■ I consent to a copy of this form and all attachments being provided to the institution.

☐ I do not consent to a copy of this form and all attachments being provided to the institution.

Attachments

The following documents have been attached (if available):

☒ Copy of the request.

■ Copy of the institution's decision letter.

■ Appeal fee made payable to the Minister of Finance (if required).

Information and Privacy
Commissioner/Ontario

Details of the Appeal

Please select the box(es) that explain why the appeal is being made.

☐ **Deemed Refusal** – It is more than 30 days since I made my request and I have not received a decision.

☐ **Failure to Disclose Records** – The institution decided to grant access to requested records but I have not received them.

☐ **Time Extension** – The institution decided to extend the time limit for responding to my request, and I disagree.

☐ **No Jurisdiction** – The institution indicated that the requested records are excluded from the *Act* and I disagree.

☒ **Reasonable Search** – The institution indicated that some or all of the requested records do not exist and I believe that more records do exist.

☐ **Frivolous or Vexatious** – The institution indicated my request is frivolous or vexatious and I disagree.

☒ **Exemptions** – The institution has exempted all or part of the requested records and I believe that more of them should be disclosed.

☐ **Interim Decision** – Because of the number of records at issue, the institution reviewed a sample of the records or consulted an experienced employee, advised me of the exemptions that might apply, and provided me with a fee estimate. I disagree with the amount of the fee estimate.

☐ **Fee/Fee Estimate** – The institution sent me an access decision that included a fee or fee estimate that I feel is excessive.

☐ **Fee Waiver** – The institution has refused to grant my request to waive the fees.

☐ **Refusal to Confirm or Deny** – The institution has refused to confirm or deny the existence of the requested records.

☐ **Correction** – The institution has refused to make corrections to my personal information.

☐ **Third Party** – The institution has indicated it will grant access to a record/personal information that may relate to me or the appellant, and I feel this information should not be disclosed.

☐ **Other** – please explain:

Information and Privacy Commissioner/Ontario

Resolution of Appeal

Please describe how you feel this appeal could be resolved.

Please see the attached letter dated October 28, 2015, which outlines the reasons for this appeal.

Previous Appeals

Please list any previous appeals with the Information and Privacy Commissioner/Ontario that may relate to this matter.

Information about the Appeal Process

For more information about the processes of the Information and Privacy Commissioner/Ontario and the Code of Procedure for appeals, please contact our office at 416-326-3333, toll-free at 1-800-387-0073, or visit our website at www.ipc.on.ca.

Where to Send this Form

This form, the applicable fee, and any additional documentation must be sent in writing to the Registrar within 30 days after the institution has given notice of its decision. The cheque should be payable to the Minister of Finance. **DO NOT SEND CASH.** Mail the above to:

Dear Ms. Ledwell:

Re: Request for Information under the Freedom of Information and Protection of Privacy Act

Please consider the following as a request for information under the *Freedom of Information and Protection of Privacy Act* (*FIPPA*):

On Januay 30th, 2014 Anne Cameron of MECC wrote:

"The Ministry of the Environment and Climate Change maintains a public file and a confidential file for the Whiskey Jack 2012-2022 Forest Manage Plan project. You are welcome to view the public file at a time and date agreed upon by yourself and the ministry (myself). Alternatively, you are able to submit a Freedom of Information request in order to obtain the complete file. This can be done using the information found at https://www.ontario.ca/government/how-make-freedom-information-request ."

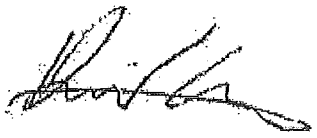
We request:

1. All records contained in the confidential MOECC file for the Whiskey Jack 2012-2022 Forest Management Plan project. We do not require any documents that were submitted by Earthroots. Please list any documents in the file that have already been provided to Earthroots, but copies are not required.
2. Any other records which the MOECC relied on in making the decision on the request for individual environmental assessment of the Whiskey Jack 2012-2022 Forest Management Plan submitted by Grassy Narrows and Earthroots.

A payment for the sum of $5.00 (five dollars) to the Minister of Finance will be made by credit card over the phone through the MOECC Freedom of Information Unit.

If you have any questions with respect to the above please do not hesitate to contact me via email at david@earthroots.org.

Sincerely,



David Sone

Toronto, ON M5V 3A8

Dear David Sone:

RE: *Freedom of Information and Protection of Privacy Act* Request
Our File #: A-2015-00157

This letter is in response to your request made pursuant to the *Freedom of Information and Protection of Privacy Act* relating to Records contained in the confidential MOECC file for the Whiskey Jack 2012-2022 Forest Management Plan project, and any other records related to the Ministry's decisions on the request for individual environmental assessment of the Plan.

After a review of the records received from the Ministry's Environmental Approvals Branch, the final decision has been made to provide partial access to the information as the identity of complainants has been removed to protect privacy (Section 21(1)(f) of the Act). In addition, advice and recommendations made by staff during the deliberative process have been withheld to encourage the free flow of advice in the government's decision-making process (Section 13(1)). Furthermore, communications and documentation exchanged between ministry staff and legal counsel as part of ongoing advice has been withheld to maintain solicitor-client privilege (Section 19(1)(a)(b)); publicly available information such as newspaper articles have been withheld (Section 22(a)); and records or information that is not relevant to the request have been removed and marked 'not responsive' or 'N/R'. Duplicate records have also been withheld.

Adjusted Fees:

In accordance with Section 57 of the *Freedom of Information and Protection of Privacy Act*, detailed below are our charges:

• Search Time 2 hours @ $30/hour	$60.00
• Copying 770 pages @ $0.20/page	$154.00
• Preparation Time 2 hours @ $30/hour	$60.00
• Delivery	$3.00
• **Total**	**$277.00**
• Deposit Received	$151.50
• **Balance Due**	**$125.50**

In order to receive a copy of the records please forward this amount to our office. You may pay by money order or cheque (made payable to the "Minister of Finance (FOI)") or by credit card. Credit card forms are available on the Ministry's website http://www.ontario.ca/environment-and-energy/freedom-information-request-form-credit-card-form. Please do not mail cash.

The Act provides that all or part of the fee can be waived if the fee will cause you financial hardship or if dissemination of the record will benefit public health or safety, in accordance with Section 57. You will be required to provide evidence to support any waiver claim in writing to the Ministry. It may be advantageous to access the Information and Privacy Commission's (IPC) website, www.ipc.on.ca to review successful fee waivers and get additional information on FOI legislation.

You may request a review of my decision by contacting the Information and Privacy Commissioner/Ontario, 2 Bloor Street East, Suite 1400, Toronto, ON M4W 1A8 (800-387-0073 or 416-326-3333). Please note that there is a $25.00 fee and you only have 30 days from receipt of this letter to request a review.

If you have any questions regarding this matter, please contact Oksana Budjko at oksana.budjko@ontario.ca.

Yours truly,

for Heidi Ritscher

January 22, 2016

Re: Appeal of disclosure from the Ministry of the Environment and Climate Change
A-2015-00158

Please accept this letter of appeal of the Ministry of the Environment and Climate Change's ("MOECC") disclosure decision, file no. A-2015-00158. This letter provides details about the grounds for appeal and the possible resolution of this matter.

Enclosed please find a copy of the Appeal Form dated January 22, 2016, the appellant's request for documents dated January 8, 2015, the MOECC's decision letter dated December 23, 2015 (received on January 6, 2016) and a cheque addressed to the Minister of Finance for $25.00.

Please note that a related appeal was filed with the Information and Privacy Commissioner (PA15-567) on October 28, 2015.

Request for Information under the *Freedom of Information and Protection of Privacy Act*, RSO 1990, c F31 *("FIPPA")*

This appeal relates to the following request for disclosure from the MOECC on January 8, 2015:

> We request all records as defined under FIPPA in possession, management or control of the MOECC that address, identify, discuss, refer, relate, or respond to:
>
> a) Grassy Narrows and Earthroots' request for individual environmental assessment of the Whiskey Jack Forest Management Plan 2012-2022.
> b) Any other matters related to the Whiskey Jack Forest Management Plan 2012-2022.
> c) The release of mercury from clearcut logging and associated issues.

Background

This request for information from the MOECC relates to the Ministry of Natural Resources and Forestry's ("MNRF") Whiskey Jack Forest Management Plan 2012-2022. Earthroots and Grassy

Narrows First Nation ("GNFN") requested that the MOECC order that MNRF conduct an Individual Environmental Assessment ("IEA") in respect of the potential release of mercury to the water system, methylmercury uptake in fish, and the resulting human health effects from eating the fish that would arise from clearcut logging authorized under the Plan. The MOECC refused the request for an IEA. The Whiskey Jack Forest Management Plan 2012-2022 is now in effect. Earthroots and GNFN are concerned about the mercury health effects of clearcut logging in the Whiskey Jack Forest which was authorized by the Plan.

Request for Review

A. Reasonable Search

(a) Attachments not included in release package

The following documents are attachments to emails disclosed in the release package. These attachments are also responsive to the request for information and should be disclosed. If any of these documents are included in the release package, we request that MOECC identify them.

1- Page 1 (PDF page 36) – Email dated June 16, 2015

Please disclose the following attachments: (1) "#2878 – Grassy Narrows First Nation_Advice Note Template.doc", (2) 2878 – Grassy Narrows First Nation.pdf, and (3) 2878a – Grassy Narrows First Nation.

2- Page 81 (PDF page 69) – Email dated May 29, 2014.

Please disclose the following attachments: (1) GN and ER comments on MNR Response to WJ IEA Request May 26, 2014 FINAL pdf, (2) 2014 May 26 ER ANA Reply to MOE re MNR response to WJ EA Request May 26, 2014, and (3) Cover FINAL.

3- Page 498 (PDF page 250) - Email dated July 15, 2014

Please disclose the following attachments: (1) July IEA Clarification to MOE. Pdf, and (2) Whiskey Jack IEA MNR science comment July 2014.

4- Page 538 (PDF page 287) – Email April 16, 2014

Please disclose the following attachments: (1) "WhiskeyJackIEA.review1.1", and (2) "SRB Hg research_2".

5- Page 634 (PDF page 318) – Email dated March 14, 2014

Please disclose the following attachment: "284.Redox Potential In Encyclopedia of Soils in the Environment.pdf".

6- Page 756 (PDF page 431): Email dated April 22, 2014

Please disclose the following attachment: (1) WhiskeyJackIEA review1_1.docx. The MOECC should confirm whether this document is an exact duplicate of the document referred to at page 538 (PDF page 287).

7- Page 830 (PDF page 490) – Email dated December 18, 2014

Please disclose the following attachment: (1) Whiskey Jack QA Dec 18.

8- Page 1111 (PDF page 681): Email dated August 26, 2014

Please disclose the following attachment: (1): "ANA Mercury Contamination.doc".

(b) The MOECC's search was not reasonable

We request that the MOECC confirm that there are no other documents responsive to this *FIPPA* request for records. Almost all of the records in the release package appear to be from computer files. We request in particular that the MOECC release all hard copy documents, written notes, voicemail message, texts, hard copy faxes, drafts and any other records that are responsive to the request.

There are several meetings referred to in the records that have been disclosed. All notes and records created for the meetings and at the meetings, and any records created as follow up to those meetings, are also responsive to the request and should be disclosed.

1- A meeting is referred to in an email dated March 28, 2014 at page 1021 (PDF page 623). The MOECC should disclose all records prepared for the meeting, created at the meeting, or after the meeting, and any documents created to follow up on issues raised at that meeting. (See also the reference to a meeting at page 1025 (PDF page 625).

2- Several records refer to meetings between MOECC and MNRF:

   a. The email dated February 18, 2014 at page 632 (PDF page 316)
   b. The email dated February 21, 2014 at page 742 (PDF page 417)
   c. The email dated February 28, 2014 at page 105 (PDF page 86)
   d. The email dated March 20, 2014 at page 516 (PDF page 268)
   e. The email dated March 20, 2014 at pages 552-553 (PDF pages 301-302)
   f. The email dated April 16, 2014 at page 538 (PDF page 287)
   g. The email dated May 29, 2014 at page 554 (PDF page 303)

   All records created relating to these meetings or any other meetings held between MOECC and MNRF related to the Whiskey Jack Forest Management Plan 2012-2022 or the IEA request are responsive to the *FIPPA* request but have not yet been disclosed. The

records should include documents prepared for the meetings, created at the meetings or after the meetings, and any records created to follow up on issues raised at the meetings.

The MOECC's decision not to grant Earthroots' and GNFN's request for an IEA was significant and took one year to finalize. There are very few documents relating to the substance of that decision in the release package. We request that the MOECC confirm that there are no other documents related to background research or drafts of the decision, or any other documents that relate to prong (a) of the information request, namely, "we request all records as defined under FIPPA in possession, management or control of the MOECC that address, identify, discuss, refer, relate, or respond to (a) Grassy Narrows and Earthroots' request for individual environmental assessment of the Whiskey Jack Forest Management Plan 2012-2022".

As well, we request the following documents:

1- The email dated July 30, 2013 at page 47 (PDF page 36) refers to a MNR[F]/MOE[CC] plan to conduct a study on the impacts of logging. MOECC should disclose all records related to the planning for this study. If the study was conducted, MOECC should disclose all records generated by the study including any findings from the study. We request any records created that follow up on the results of this study.

2- The email dated February 5, 2013 at page 63 (PDF page 51) refers to a project to look at the effects of logging on Hg concentrations in fish. MOECC should disclose all records related to the planning for this study. If the study was conducted, MOECC should disclose all records generated by the study including any findings from the study. We request any records created that follow up on the results of this study.

3- The email dated February 28, 2014 at page 105 (PDF page 86) refers to work Dr. Satyendra Bhavsar completed on "fish Hg/ logging". MOECC should disclose all records related to the planning for this study. If the study was conducted, MOECC should disclose all records generated by the study including any findings from the study. We request any records created that follow up on the results of this study.

4- The Information Note at pages 167 - 174 (PDF pages 126 – 133) refers to several studies. MOECC should disclose all documents related to the January 2011- March 2011 study referred to at page 168 (PDF page 127).

   The Information Note also refers to an MOEEC and MNRF discussion about a potential study to look at the effects of logging and clearcutting on mercury levels in fish at page 169 (PDF page 128). MOECC should disclose all records related to the planning for this study. If the study was conducted, MOECC should disclose all records generated by the study including any findings from the study. We request any records created that follow up on the results of this study.

   The email dated August 7, 2013 at page 656 (PDF page 335) refers to Dr. Satyendra Bhavsar working with MNR[F] to set up a study using "SF data" regarding the relationship between different logging practices and Hg in fish. MOECC should disclose

all records related to the planning for this study. If the study was conducted, MOECC should disclose all records generated by the study including any findings from the study. We request any records created that follow up on the results of this study.

5- The email dated April 16, 2014 at page 538 (PDF page 287) refers to a review by MOECC of science documentation provided by MNRF. MOECC should disclose all documents related to this review and any other science review conducted by MOECC during the IEA process.

6- The email dated April 22, 2014 at page 756 (PDF page 431) refers to Dr. Fletcher's comments on MNR[F]'s reply. MOECC should disclose all documents related to this review of MNRF's reply.

7- The email dated July 28, 2014 at page 1668 (PDF page 1044) refers to two reports. One is the report referenced by the media in relation to the Mercury Disability Board, and the other is a University of Ottawa report funded by Health Canada. MOECC should disclose these reports.

8- The email dated July 30, 2014 at page 740 (PDF page 415) refers to an "informal working group of scientists to better understand the impacts of logging and from a science view whether there are ways to mitigate the effects of Hg from logging". MOECC should disclose all records related to the working group.

9- We also request all drafts and all records created in relation to or as follow up after the Decision Note at pages 1326-1335 (PDF pages 885-894).

B. Documents that cannot be read or identified

Portions of the following documents are not readable and we ask that a new copy be disclosed. If a better copy is not available, we request that MOECC ask that the author of the document identify the document and record what it says: (1) email dated February 2, 2014 at page 53 (PDF page 41), (2) email dated June 7, 2012 at page 55-57 (PDF page 43-45), and (3) email dated May 29, 2014 at page 81 (PDF page 69).

There are also a significant number of documents that have been withheld in their entirety under section 13 or have been marked as "not relevant. There is no way to identify these documents or determine whether these characterizations should be upheld. We therefore request that the MOECC create an Index of Records which provides clear information that identifies the date, author, recipients, copied parties, subject of the documents, and an explanation of the application of subsection 13(1) or their characterization as "not relevant".

In particular, we ask that the MOECC identify each document redacted in its entirety under section 13 and explain why section 13 applies to the whole document.These documents include but are not limited to:

1- Pages 821-822 (PDF page 483)
2- Pages 825-826 (PDF page 486)
3- Pages 831-833 (PDF page 491)
4- Pages 836-838 (PDF page 494)
5- Pages 840-043 (PDF page 496).
6- Pages 850-854 (PDF page 503)
7- Pages 929-938 (PDF page 567)
8- Pages 939-943 (PDF page 568)
9- Pages 944-945 (PDF page 569)

It is CELA's position that section 13 has been improperly applied to these documents and we ask that the documents be disclosed. They are not properly classified under subsection 13(1), are properly classified under subsection 13(2), and should be disclosed pursuant to section 23. Disclosure of these documents would serve the purposes of the *FIPPA* regime under section 1. In the alternative, the MOECC should ensure that the documents are released to the extent possible under subsection 10(2) of *FIPPA*.

There are also a significant number of documents in the release package which have been withheld in their entirety and marked as "not relevant". There is no way to identify these documents or to determine whether these documents have been appropriately classified as not relevant. We ask that the MOECC identify these documents and explain their characterization as not relevant. We ask that all of the documents marked as not relevant be disclosed.

C. Section 13 has been improperly applied

Section 13 has been improperly applied throughout the release package and we ask that these documents be disclosed because they are not properly classified under subsection 13(1), are properly classified under subsection 13(2), and should be disclosed pursuant to section 23. Disclosure of these documents would serve the purposes of the *FIPPA* regime under section 1.

Many of the documents are background information or scientific reviews. There is a compelling public interest in their disclosure. They relate to very serious health and environmental issues arising from the Whiskey Jack Forest Management Plan 2012-2022 and the MOECC's decision not to order an IEA.

There is a strong public interest in understanding the basis for the MOECC's decision. These documents would shed light on the operations of government and allow the public to assess the rigour and fairness of the IEA decision-making process in this case.

In particular, section 13 has been improperly applied in the following documents and the information withheld under section 13 should be disclosed:

1- The email chain dated August 7, 2014 at pages 656-657 (PDF pages 335-336).

2- The email chain dated July 31, 2014 at pages 740-741 (PDF pages 415-416).

3- The email dated January 10, 2014 at page 760 (PDF page 435).

4- The email dated March 31, 2014 at page 814 (PDF page 476).

5- The email dated April 1, 2014 at page 815 (PDF page 477).

6- The email chain dated December 18, 2014 at pages 827-829 (PDF pages 487-489).

7- The email chain dated April 1, 2014 at pages 1238- 1243 (PDF pages 797-802).

8- Decision Note at pages 1326-1335 (PDF pages 885 – 894).

D. Redaction to document at page 39 (PDF page 32)

Please disclose the full document at page 39 (PDF page 32). The reason for the redactions has not been disclosed.

Thank you for your consideration of this matter. Please note that I will be out of the office from January 22, 2016- February 8, 2016 without access to email. During that time, if you require immediate assistance, please contact my colleague Joseph Castrilli at 416-960-2284 ext. 218 or castrillij@sympatico.ca.

Institution Information (if available)

NAME OF INSTITUTION Minister of the Environment and Climate Change

INSTITUTION FILE NUMBER A-2015-00158

Consent to Provide a Copy of Documentation to the Institution

Please select *one* of the following:

■ I consent to a copy of this form and all attachments being provided to the institution.

☐ I do not consent to a copy of this form and all attachments being provided to the institution.

Attachments

The following documents have been attached (if available):

☒ Copy of the request.

■ Copy of the institution's decision letter.

■ Appeal fee made payable to the Minister of Finance (if required).

Information and Privacy Commissioner/Ontario

Details of the Appeal

Please select the box(es) that explain why the appeal is being made.

☐ **Deemed Refusal** – It is more than 30 days since I made my request and I have not received a decision.

☐ **Failure to Disclose Records** – The institution decided to grant access to requested records but I have not received them.

☐ **Time Extension** – The institution decided to extend the time limit for responding to my request, and I disagree.

☐ **No Jurisdiction** – The institution indicated that the requested records are excluded from the *Act* and I disagree.

☒ **Reasonable Search** – The institution indicated that some or all of the requested records do not exist and I believe that more records do exist.

☐ **Frivolous or Vexatious** – The institution indicated my request is frivolous or vexatious and I disagree.

☒ **Exemptions** – The institution has exempted all or part of the requested records and I believe that more of them should be disclosed.

☐ **Interim Decision** – Because of the number of records at issue, the institution reviewed a sample of the records or consulted an experienced employee, advised me of the exemptions that might apply, and provided me with a fee estimate. I disagree with the amount of the fee estimate.

☐ **Fee/Fee Estimate** – The institution sent me an access decision that included a fee or fee estimate that I feel is excessive.

☐ **Fee Waiver** – The institution has refused to grant my request to waive the fees.

☐ **Refusal to Confirm or Deny** – The institution has refused to confirm or deny the existence of the requested records.

☐ **Correction** – The institution has refused to make corrections to my personal information.

☐ **Third Party** – The institution has indicated it will grant access to a record/personal information that may relate to me or the appellant, and I feel this information should not be disclosed.

☐ **Other** – please explain:

Information and Privacy Commissioner/Ontario

Resolution of Appeal

Please describe how you feel this appeal could be resolved.

Please see the attached letter dated January 22, 2016, which outlines the reasons for this appeal.

Previous Appeals

Please list any previous appeals with the Information and Privacy Commissioner/Ontario that may relate to this matter.

This appeal relates to appeal PA15-567 (Ministry of the Environment and Climate Change - A-2015-00157).

Information about the Appeal Process

For more information about the processes of the Information and Privacy Commissioner/Ontario and the Code of Procedure for appeals, please contact our office at 416-326-3333, toll-free at 1-800-387-0073, or visit our website at www.ipc.on.ca.

Where to Send this Form

This form, the applicable fee, and any additional documentation must be sent in writing to the Registrar within 30 days after the institution has given notice of its decision. The cheque should be payable to the Minister of Finance. **DO NOT SEND CASH.** Mail the above to:

Dear Ms. Ledwell:

Re: Request for Information under the Freedom of Information and Protection of Privacy Act

Please consider the following as a request for information under the *Freedom of Information and Protection of Privacy Act* (*FIPPA*):

We request all records as defined under FIPPA in possession, management or control of the MOECC that address, identify, discuss, refer, relate, or respond to:

a) Grassy Narrows and Earthroots' request for individual environmental assessment of the Whiskey Jack Forest Management Plan 2012-2022.
b) Any other matters related to the Whiskey Jack Forest Management Plan 2012-2022.
c) The release of mercury from clearcut logging and associated issues.

Any records previously provided to Earthroots need not be provided.

A payment for the sum of $5.00 (five dollars) to the Minister of Finance will be made by credit card over the phone through the MOECC Freedom of Information Unit.

If you have any questions with respect to the above please do not hesitate to contact me at via email at david@earthroots.org.

Sincerely,

David Sone

Dear David Sone:

RE: *Freedom of Information and Protection of Privacy Act* Request
Our File # A-2015-00158

This letter is further to your request made pursuant to the *Freedom of Information and Protection of Privacy Act* relating to Records related to the Grassy Narrows and Earthroot's request for individual assessment of the Whiskey Jack 2012-2022, and any other matters related to this plan. As well, the release of mercury from clearcut logging and associated issues..

Attached is a copy of the records.

If you have any questions regarding this matter, please contact Oksana Budjko at oksana.budjko@ontario.ca.

Yours truly,

Respondents

SUPPLEMENTARY AFFIDAVIT OF JOSEPH FOBISTER

I, JOSEPH FOBISTER, of Grassy Narrows, in the District of Kenora, AFFIRM AND SAY AS FOLLOWS:

1. I am a Band member of the Grassy Narrows First Nation ("Grassy Narrows"), and I have acted as advisor to former Chief Simon Fobister on logging issues, and negotiator for Grassy Narrows on logging issues between 2007 and 2014. I have continued to work with

current Chief Roger Fobister, Senior on the bump-up request referred to below and matters arising from that issue. As such I have knowledge of the matters hereinafter deposed to.

FIPPA REQUEST TO MOECC

2. I have read the supplementary affidavit of David Sone, sworn March 9, 2016, and the exhibits contained therein. The efforts of Mr. Sone to obtain information under the *Freedom of Information and Protection of Privacy Act* ("*FIPPA*") from the Ministry of the Environment and Climate Change ("MOECC") about its consideration of the issue of mercury during the bump-up request process described in detail in Mr. Sone's supplementary affidavit, were in furtherance of the joint efforts of Grassy Narrows and Earthroots Coalition ("Earthroots") discussed in my earlier affidavit, affirmed August 26, 2015, to obtain information about the extent to which the release of mercury to area waterbodies from clearcut logging was addressed by the Ministry of Natural Resources and Forestry ("MNRF") prior to its decision to approve the 2012-2022 Whiskey Jack Forest Management Plan ("Plan").

3. I also agree with paragraphs 5-9 and 17 of Mr. Sone's supplementary affidavit. Grassy Narrows was not privy to the communications or discussions or aware of the existence of on-going contact and collaboration that was taking place between MOECC and MNRF during the bump-up request process that is revealed in Mr. Sone's supplementary affidavit and exhibits.

4. I affirm this supplementary affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIRMED before me in the District of Kenora, in the Province of Ontario, this ___ day of _____, 2016.

A Commissioner, etc.

SUPPLEMENTARY AFFIDAVIT OF ROGER FOBISTER, SENIOR

I, ROGER FOBISTER, SENIOR, of Grassy Narrows, in the District of Kenora, AFFIRM AND SAY AS FOLLOWS:

1. I am one of the applicants in the within application for judicial review, and as such have knowledge of the matters hereinafter deposed to.

2. I am a member of the Grassy Narrows First Nation (hereinafter "Grassy Narrows"). I have been its elected Chief since April 2014.

3. I have read the supplementary affidavit of David Sone, sworn March 9, 2016. I agree with paragraphs 5-9 and 17 of Mr. Sone's supplementary affidavit. Neither Grassy Narrows nor I were privy to the communications or aware of the existence of on-going contact and collaboration between the Ministry of the Environment and Climate Change ("MOECC") and the Ministry of Natural Resources and Forestry ("MNRF") during the period of my tenure as Chief and our request was before MOECC (April to December 2014) for an individual environmental assessment ("IEA") of the potential mercury impacts of clearcut logging arising from the MNRF decision to approve the 2012-2022 Whiskey Jack Forest Management Plan.

4. I only learned of the fact, nature, frequency, and extent of the MOECC/MNRF contact and collaboration on our IEA request upon reading Mr. Sone's supplementary affidavit.

5. I affirm this supplementary affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIRMED before me in the City of Toronto, in the Province of Ontario, this ___ day of _____, 2016.

AFFIDAVIT OF SHIGERU TAKAOKA

I, SHIGERU TAKAOKA, of the City of Minamata, in the Prefecture of Kumamoto, Japan MAKE OATH AND SAY AS FOLLOWS:

1. I am a medical doctor and director of the Kyoritsu Neurology and Rehabilitation Clinic, in the City of Minamata, in the Prefecture of Kumamoto, where I specialize in the areas of neurological, rehabilitative, and general internal medicine. I have participated in clinical examinations of patients suspected of having been exposed to mercury in

Minamata, Japan and Grassy Narrows, Ontario, Canada, the latter experience as part of a team of researchers lead by the late Dr. Masazumi Harada. In addition to my clinical work, I am also the co-author of several articles on the subject of exposure to mercury that have been published in a number of peer-reviewed medical and scientific journals. A copy of my curriculum vitae is attached to Exhibit "A", below.

2. In December 2015 I, along with my colleagues Drs. Tadashi Fujino and Akitomo Shimoji were asked by counsel for Grassy Narrows First Nation to answer certain questions on medical-psychological/psychiatric issues pertaining to mercury exposure at Grassy Narrows. The questions and our answers to them appear as part of our May 2016 expert report attached as Exhibit "A" to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "B" to my Affidavit.

SWORN BEFORE ME in the City of Minamata, in the Prefecture of Kumamoto, Japan, this ___ day of _____, 2016.

A Commissioner, etc.

高岡滋の宣誓供述書

私、日本国熊本県水俣市在住の高岡滋は下記のことを宣誓供述致します。

1. 私は医師で熊本県水俣市の神経内科リハビリテーション協立クリニック院長であります。私の専門は神経内科とリハビリテーション、そして一般内科です。私は日本の水俣市とカナダ国オンタリオ州グラッシーナローズにて水銀汚染されたと疑われる患者の住民健診に参加しました。グラッシー・ナローズにおいては原田正純医師率いる調査チームに参加しました。臨床経験に加え、私は水銀汚染に関する論文をいくつか共同で執筆し、それらは論文審査のある医学科学専門誌で発表されました。以下の証拠品 A に私の履歴書が添付されています。

2. 2015 年 12 月に私と同僚の藤野糺医師、下地明友医師に対してグラッシー・ナローズ・ファースト・ネーションの弁護士からグラッシー・ナローズにおける水銀汚染に係る医学的、心理学的、そして精神的影響に関するいくつかの質問に回答するように依頼されました。質問と回答は私の供述宣誓書に証拠品 A として添付されている 2016 年 5 月専門家報告書に記載されています。

3. 私の専門家全責任承認フォーム 1 部が証拠品 B として私の供述宣誓書に添付されています。

Introduction: Expertise and Qualifications

We are three doctors who practice in Kumamoto Prefecture on the island of Kyushu in Japan. The following is a brief summary of our experience and expertise:

Dr. Shigeru Takaoka: I am a medical doctor and director of the Kyoritsu Neurology and Rehabilitation Clinic, Minamata, Kumamoto, Japan where I specialize in a number of areas, including neurological, rehabilitative, and general internal medicine. I have participated in clinical examinations of patients suspected of having been exposed to mercury in Minamata, Japan and Grassy Narrows, Ontario, Canada, the latter experience as part of a team of researchers lead by the late Dr. Masazumi Harada. In addition to my clinical work, I am also the co-author of several articles on the subject of exposure to mercury that have been published in a number of peer-reviewed medical and scientific journals.

Dr. Tadashi Fujino: I am a medical doctor specializing in psychiatry and neurology at Kumamoto Hospital. I have considerable clinical experience examining patients exposed to mercury in Minamata, Japan. At various times, over several decades, I also undertook, with a team of researchers lead by the late Dr. Masazumi Harada, many clinical examinations of men, women, and children suspected of being exposed to mercury in Grassy Narrows, Ontario, Canada. I have written extensively about my clinical investigations in both countries in numerous medical and scientific peer-reviewed journals.

Dr. Akitomo Shimoji: I am a medical doctor, neuro-psychiatrist, and professor at Kumamoto Gakuen University. Along with a team of researchers lead by the late Dr. Masazumi Harada, I participated in clinical examinations of patients exposed or suspected of having been exposed to mercury in Grassy Narrows, Ontario, Canada. Based on my clinical experience in Japan, I also have authored or co-authored several articles that have been published in peer-reviewed medical and scientific journals on the subject of exposure to mercury.

Our curriculum vitae appear in Appendix B of our Expert Report.

Instructions and Nature of Professional Opinion Sought

We have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare an expert report that responds to four questions that are reproduced below. We are solely responsible for the answers to the questions contained in this report. Page references contained in the questions set out below are from the Applicants' Application Record in *Grassy Narrows First Nation, et al v. Minister of Natural Resources and Forestry (Ontario), et al.*

List of Questions Asked

Questions for Dr. Shigeru Takaoka et al.		
English	Japanese	Reference Page
Question 1: Based on the clinical medical examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on the statements, which appear below respecting pages 001251 to 001252 of the January 2014 request by Grassy Narrows (GN) to the Government of Ontario, and whether they are accurate in their summary of the findings of Dr. Harada's team based on the two Harada referenced reports of 2005 and 2011 that appear at page 001284 of the January 2014 request?		
Excerpt from: Bump-up Request for an Individual Environmental Assessment (IEA) submitted to the Ontario Ministry of the Environment regarding the Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022 - Final Plan Inspection Approved by the Ministry of Natural Resources, December 23, 2013 - EBR Registry No. 010-9240 Submitted by: Grassy Narrows First Nation and Earthroots January 22, 2014 5. Mercury Impacts Human Health in Grassy Narrows SUMMARY 35 Years of study by renowned mercury expert Dr. Harada and his team have confirmed that people in Grassy Narrows are suffering from Minamata Disease as a result of methyl mercury ingested by eating local fish. EVIDENCE Doctor Harada's teams of researchers have studied mercury health impacts in Grassy Narrows for over 35 years starting in 1975. "[I]t is an undoubtable fact that Minamata Disease occurred in [Grassy Narrows and White Dog], based on our long-term investigation result." (Harada et al., 2011) Grassy Narrows people "were poisoned by eating fish contaminated with mercury." (Harada et al., 2011) Findings by Harada et al., 2011 • 59% of the 160 people tested in GN and White Dog were affected by mercury. • 34% were diagnosed with Minamata Disease (MD)		1251-1252

using current Japanese diagnostic criteria (41% in GN --> 30 cases) • 25% were diagnosed with suspected Minamata Disease (SMD) • 44% of people aged 21-40 had MD or SMD. All these people were born after the mercury dumping was curtailed in 1971. "[T]he possibility of congenital Minamata Disease occurrence is very high in these two communities. We examined 7 cases of cerebral palsy and 7 cases of mental deficiency.... Further epidemiological research on stillbirths and miscarriages needs to be done." (Harada et al., 2005) All of Dr. Harada's patients who indicated mercury levels higher than the safetyguideline of 50 ppm in 1975 were deceased by 2004. (Harada et al., 2005)

"Mercury Poisoning in First Nations Groups in Ontario, Canada 35 Years of Minamata Disease in Canada." Journal of Minamata Studies 3: 3–30. Harada, Masazumi, Masanori Hanada, Takashi Miyakita, Tadashi Fujino, Kazuhito Tsuruta, Akira Fukuhara, Tadashi Orui, Shigeharu Nakachi, Chihito Araki, and Masami Tajiri. 2005. "Long-Term Study on the Effects of Mercury Contamination on Two Indigenous Communities in Canada (1975-2004)." Research on Environmental Disruption 34 (4).		1284
Question 2: Based on the clinical medical examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on the statements, which appear below respecting pages 001445, 001479 to 001483 of the September 2014 supplementary GN submissions to the Government of Ontario, and whether they are accurate in their summary of the findings of Dr. Harada's team referred to in those pages?		

The following 5 Excerpts are from: Literature Review regarding the Impact of Mercury on Human Health Summary of a text produced by Drs. Laurie Chan and Donna Mergler for the Mercury Disability Board presented by Donna Mergler PhD, Professor Emerita, University of Quebec at Montreal: Dr. Harada's studies • Dr. Harada did pioneering work in Japan, demonstrating neurologic damage of Minamata Disease • In a recent report, he stated: "During the early stages of the MD crisis in Minamata, patients, who were diagnosed with MD, seemed to be typical and severe cases of the Hunter-Russell syndrome, including sensory disturbance, concentric constriction of the visual field, ataxia, speech impairment and impaired hearing. However, through more study, it became clear that such severe cases were rather exceptional and many more mild cases were progressing to chronic Minamata Disease. I observed that the symptoms of Minamata Disease became more chronic and atypical in the 1970s. Also I have been proving that sensory disturbances, specifically stronger loss of sensation in the extremities, were seen among patients of methylmercury poisoning at a very high rate, through clinical examinations on family members of patients with sever(sic) and typical symptoms or mothers of congenital Minamata Disease patients"		1479
Dr. Harada's studies • In the '70s, he showed that persons in Grassy Narrows and White Dog manifested similar signs and symptoms to MD and there appeared to be a dose-relation with mercury exposure • In 2002 and 2004, he and his team went back. In total they examined 156 people from Grassy Narrows and White Dog. • Age ranged from 1-90 years • No information was provided on how persons were recruited		1480
Dr. Harada's studies • Diagnostic criteria: • MD: more than one symptom of: sensory disturbances, ataxia, disturbed ocular movement, imbalance, concentric constr[i]ction of the visual field and speech impairment. • In cases where examinees were showing only sensory disturbances, we acknowledged MD as long as there was no other disease causing the symptom. • If an examinee had another disease and still showed symptoms of MD that were not explained by that other disease, we defined the case as MD with complications.		1481

Dr. Harada's studies • Findings: • 60 cases of MD (34.2% of total examinees, excluding people 10 years old and younger); • 54 cases (30.8%) of MD with complications; • 25 cases (14.2%) of possible MD for a total of 139 cases (79.4%). • They conclude : • It is very high rate of neurological symptoms for a sample of a population, even though examinees came because of other health issues. It is as high as contaminated areas in Minamata. We cannot help but recognize the effects of methylmercury from the symptoms we have seen.		1482
Our conclusions [of Drs. Chan and Mergler] • Dr Harada and his group did not evaluate the prevalence of MD in this population, but reported on the percentage of MD signs and symptoms within the group that they examined. • We consider that Dr. Harada's follow-up clinical evaluation should be seen as a preliminary study showing the need for a comprehensive epidemiologic study that would include all of the known outcomes of mercury exposure and could take into account co-morbidity from other diseases, such as diabetes and /or alcohol and test for possible interactions. Such a study should also take into account the presence of other contaminants. For this study it would be most useful to have all of the results of hair and blood sampling by Health Canada, Dr. Chan and Dr. Harada, as well as the results of the neurological examinations that were done by Dr. Harada.		1483
Question 3: Based on the clinical psychological/psychiatric examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on whether you agree with the statements of Donnan, 1986, regarding the psychological health impacts of mercury/methylmercury, which statements appear below respecting pages 001492 to 001493 of the November 2014 supplementary GN submissions to the Government of Ontario? In your professional opinion, has exposure to mercury had psychological/psychiatric impacts on the people of Grassy Narrows and, if so, what have been those impacts?		

Excerpts from: Grassy Narrows and Earthroots Fourth Supplementary Submission to Devon Wills, Ministry of the Environment on 2012-2022 Whiskey Jack Forest Management Plan IEA Request, dated November 14, 2014 2. PSYCHOLOGICAL HEALTH IMPACTS OF MERCURY "High blood mercury levels contribute to anxiety..." (Donnan, MOE 1986, p.28) "...mental health effects such as anxiety due to mercury contamination in the Wabigoon- English River System have been borne almost entirely by the Native people of the Grassy Narrows and Whitedog Bands." (Donnan, MOE 1986, p.28) The fear and anxiety from knowing they were contaminated was debilitating to many. The threat of mercury poisoning clearly affected the mental health of these people...." (Donnan, MOE 1986, p.31) "[A] reduction in fish mercury levels could help to reduce anxiety and mental trauma experienced by these people." (Donnan, MOE 1986, p.44)		1492-1493
Question 4: Do you continue to adopt the findings and conclusions contained in the article by Shigeru Takaoka, et al, entitled "Signs and symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" reported in Science of the Total Environment 468-469 (2014) 950-957? If not, what has caused you to change your opinion since publication of the article?		

Answers to Questions

Question No. 1

They are accurate.

Question No. 2

They are accurate.

Question No. 3

In our professional opinion, yes, there were negative psychiatric effects.

Question No. 4

We continue to support them.

HIGHLIGHTS

- Similarities between the prevalence of complaints in Minamata and Grassy Narrows
- Similarities in neurological findings were also found.
- Quantitative sensory measurements gave similar results for impairments.
- Younger Canadians were less severely affected than older ones.
- Results suggest that subjects from Grassy Narrows had methylmercury poisoning.

ABSTRACT

In 1970, fish caught in the English–Wabigoon River system in northwestern Ontario, Canada, were found to be contaminated with mercury coming from a chlor-alkali plant in the province. In the 1970s, patients exhibiting some of the symptoms of the Hunter–Russell syndrome (e.g. paresthesias, visual field constriction, ataxia, impaired hearing, and speech impairment) were reported by some researchers. However attempts to diagnose the patients as suffering from methylmercury poisoning proved to be controversial. In order to research the presence of methylmercury contamination, and show that the patients, through eating contaminated fish, were suffering from methylmercury poisoning, we studied the results of subjective complaints, neurological findings, and quantitative somatosensory measurements gathered in Grassy Narrows Indian Reservation, Ontario, in March, 2010. At that time, the population of the Grassy Narrows settlement was around 900. Ninety-one residents volunteered to be examined. From them, we selected 80 people who were older than 15 years old, and divided them into two groups. Canadian Younger (CY): 36 residents who were from 16 to 45 years old. Canadian Older (CO): 44 residents who were from 46 to 76 years old. We compared them to Japanese Exposed (JE): 88 methylmercury exposed residents from the Minamata district in Japan, and Japanese Control (JC): 164 control residents from non-polluted areas in Japan. Complaints and abnormal neurological findings were more prevalent and quantitative sensory measurements were worse in the two Canadian groups and the Japanese Exposed group than in the Japanese Control group. Complaints, neurological findings and quantitative sensory measurements were similar in Canadian Older and Japanese Exposed. The results for Canadian Younger fell between those of Canadian Older and Japanese Control. These findings indicate that the clinical signs and symptoms of the residents of Grassy Narrows are almost the same as those recorded for Minamata disease in Japan.

1. Introduction

Since the 1960s, a chlor-alkali plant had been releasing waste products contaminated with mercury into the waters of the English–Wabigoon River system in northwestern Ontario, Canada. In the first examples of fish, from the river system, that were contaminated with methylmercury (Bligh, 1970) levels of up to 16 μg/g were reported. Fimreite and Reynolds (1973) found highly contaminated fish with a maximum

023

methylmercury concentration of 27.8 μg/g in 1970. The contamination in fish there was almost equal to that measured in fish from Minamata Bay, Japan, where a barracuda was recorded as having 23 μg/g in May 1961 (Fujiki and Irukayama, 1979). The average mercury concentrations, measured in 1971, in walleye and northern pike from Ball Lake, English–Wabigoon River, were 1.99 μg/g and 5.05 μg/g respectively (Armstrong and Scott, 1979).

In 2003, results of similar measurements were 0.40 μg/g in walleye and 0.85 μg/g in northern pike (Kinghorn et al., 2007). The concentrations of mercury in fish are declining, but they are still higher than those found in fish in Minamata Bay, Japan, where the average concentration of mercury in fish has been from 0.17 to 0.42 μg/g during the period of 1998-2004. (Kindaichi and Matsuyama, 2005). Residents living in that area of Japan, still continue to be exposed to low levels of mercury from the eating of locally caught fish.

The two First Nations' communities living in Grassy Narrows and Whitedog Indian Reservations became victims of methylmercury poisoning through the consumption of locally caught fish. Patients with some of the Hunter–Russell syndrome symptoms have been reported in these reserves (Harada et al., 1976). Canadian researchers also examined the indigenous residents of the areas. Wheatley et al. (1979) reported that effects associated with methylmercury poisoning were observed, but they concluded that direct impacts on human health were difficult to prove.

Pathological studies of a cat from Whitedog, which exhibited acute neurological symptoms, revealed high mercury levels in the brain similar to those of Minamata disease in Japan (Takeuchi et al., 1977). Another cat from neighboring Grassy Narrows showed no symptoms, but on closer examination it was shown to have high mercury levels in the brain and latent defects caused by methylmercury poisoning (Takeuchi et al., 1977).

Since 2004, more than 60,000 people from the Minamata district have been diagnosed with abnormal neurological symptoms. In many cases, the abnormalities were being reported for the first time since the release of methylmercury contaminated wastewater was stopped in 1968 (Takaoka et al., 2009). In chronic methylmercury poisoning the somatosensory disturbance from cortical damage is specific and sensory disturbance is present either in all four limbs or throughout the body, sometimes with the exception of the face and head. To detect such abnormalities, quantitative sensory measurements are useful (Takaoka et al., 2008). So we carried out a health survey that included the examination of subjective complaints, neurological symptoms, and quantitative sensory measurements in Grassy Narrows, Ontario, Canada, in 2010 and tried to reassess the effect of methylmercury in this area.

2. Materials and methods

2.1. Subjects

The study was carried out in March 2010 in Grassy Narrows, Ontario, Canada. We contacted a Grassy Narrows support group and asked for their help. They informed the indigenous population of our coming survey to detect any health effects from methylmercury poisoning and asked for volunteers to take part in the study. The Chief of Grassy Narrows First Nation went on the local radio to ask for volunteers for our research. Posters, informing of our coming research project and our wish for volunteers, were displayed in the band office and a local store. Of the approximately 900 residents, 91 volunteered to be examined. We selected 80 residents, who were older than 15, for the study. Subjects were informed verbally and in writing about the examination method, how the data would be used and that their confidentiality would be protected. Each participant gave their written consent.

We divided them into two groups. (1) Group Canadian Younger (CY): consisted of 36 residents who were from 16 to 45 years old (M/F = 18/18, 34.4 ± 9.5 years old). (2) Group Canadian Older (CO): consisted of 44 residents who were from 46 to 76 years old (M/F = 19/25, 57.5 ± 8.1 years old).

We studied subjective symptoms, neurological findings and carried out four quantitative sensory measurements (including minimal tactile sensation, vibration, position sense, and two-point discrimination) among the 80 residents. In order to assess the state of health of the residents of Grassy Narrows, we compared them to a group of Japanese residents who had also been exposed to methylmercury as well as a group of Japanese control residents. These residents were the same people we had used as subjects in our previous study (Takaoka et al., 2008).

(3) Group Japanese Exposed (JE): was comprised of 88 randomly selected Japanese subjects. They were chosen from residents of the Minamata area who had been exposed to methylmercury and who had been included in our former study at the Minamata Kyoritsu Hospital and the Kyoritsu Neurology and Rehabilitation Clinic between November 2004 and April 2005. Their ages matched those of the corresponding Canadian group but the genders could not be matched exactly (M/F = 38/50, 59.0 ± 7.5). They answered a detailed questionnaire and were given a neurological examination including the same four quantitative sensory measurements as we performed in Canada. All of them were born before 1969. In our former study, we separated the subjects into those with and without neurological or neurologically related diseases, but we found that there was little difference between those two groups. So in this study, Group JE included subjects both with and without such related diseases.

(4) Group Japanese Control (JC): consisted of 164 residents who lived in other districts, e.g. around Fukuoka City, Kumamoto City, and Kagoshima City, aged between 40 and 79. In the control group, people who had lived around Minamata City or who suffered from a neurological disease or a neurologically related illness were excluded. The control subjects were examined between February and May 2006 (M/F = 67/97, 58.4 ± 11.6).

2.2. Epidemiological conditions and questionnaire on complications

The questionnaire, both in Canada and Japan, included questions to determine the subject's exposure to methylmercury and asked for information regarding place of residence, dietary habits, occupational history, medical complications and the health and medical histories of family members.

The questionnaire on complaints for the Canadian groups (CO and CY) consisted of 47 questions related to sensory impairment (7 items), somatic pain (4), visual impairment (3), hearing impairment (3), tasting and smelling problems (3), in-coordination of the extremities (4), other movement impairment (11), vertigo and dizziness (4), general complaints (2), and mental and intellectual problems (6).

The questionnaire on complaints for the Japanese groups (JE and JC) consisted of about 50 questions. We selected 35 relevant questions from the Japanese questionnaire and used them in the Canadian one. They were as follows: sensory impairment (4 items), somatic pain (3), visual impairment (3), hearing impairment (3), tasting and smelling problems (3), in-coordination of the extremities (5), other movement impairment (4), vertigo and dizziness (4), general complaints (2), and mental and intellectual problems (4).

In answer to questions on health complaints, subjects were asked to select one of 4 possible choices. 1) Yes, always, 2) Yes, sometimes, 3) Yes, in the past but not at present, and 4) No, never. The prevalence of each complaint was calculated for each group and then compared between the four groups. All subjects completed the questionnaire before their medical examination. Subjects who could not complete the questionnaire by themselves were asked the questions verbally. All questionnaires were reviewed prior to the examinations.

2507
024

2.3. Standard neurological examination

A standard neurological examination was carried out on 32 of the 36 subjects in Group CY and on all 44 subjects in Group CO. Dysarthria, auditory disturbance, visual constriction, finger–nose test with the eyes open and closed, diadochokinesis, heel–shin test, gait disturbances, tandem gait test, Mann's test, balancing on one foot with eyes open and closed, and superficial sensory disturbance (touch and pain) were used and tested for. The examination methods and criteria were almost the same as the former study (Takaoka et al., 2008).

Dysarthria, auditory disturbance, visual constriction, postural hand tremors, gait disturbances and Romberg's sign were judged to be either present or absent. Dysarthria, auditory disturbance, and visual field constriction were judged by the examining physician without using special instruments. Tunnel vision was considered to be present when the confrontation test showed a lateral field of vision of 80° or less.

Limb and truncal ataxia were judged as being either absent, mildly abnormal or moderately to severely abnormal. The results of the finger–nose test and the heel–shin test were judged to be positive not only when there was constant dysmetria or decomposition but also when there was uncertain dysmetria, decomposition, or very slow movement involved. Dysdiadochokinesis was judged to be present from when there was a constant abnormality to when there was an uncertain abnormality or slow movement. Tandem gait disturbance was judged as present not only when the subject could not walk more than five steps but also when they could walk five steps but were unstable. In the balancing on one foot test, disequilibrium was judged as present when it was impossible to balance more than 3 s or when the subject was unstable, but could keep their balance for more than 3 s.

The examinations were carried out in Canada by one neurologist and four psychiatrists. The neurologist and two of the psychiatrists had previous experience in carrying out these tests from earlier examinations of Minamata disease patients. The other two psychiatrists had been briefed and trained to carry out the tests. In Japan, Group JE was examined by six physicians and one neurologist and Group JC was examined by forty-five physicians, several of whom were neurologists.

Because there was not enough data collected from Group JE for the finger–nose test with eyes closed, Mann's test, Romberg's sign or balancing on one foot with eyes closed test, we excluded that information from our calculations.

2.4. Quantitative sensory measurements

Four categories of tests were used in the quantitative measurement of the somatosensory system. All four categories were the same as in the former study (Takaoka et al., 2008).

2.4.1. Assessment of minimal tactile sense

The minimal tactile sense was measured by the Semmes–Weinstein monofilament test. Twenty kinds of filaments from 0.008 to 300 g were used. Subjects were tested with eyes closed after receiving clear instructions on which locations would be tested. Each filament was pushed until it bent about 90° for about a second. The threshold was the smallest size filament which a subject could feel as touch. The trial was performed starting from a smaller size filament and then gradually increasing the size.

Each filament was tested only once except when the subject was unsure. In that case the examiner, using the same filament, repeated the test an odd number of times and selected the dominant response. If a subject could not detect the maximum filament (300 g), we defined the threshold as 400 g for calculation. Testing was carried out on the lower lip, upper chest and ventral sides of both index fingers and big toes.

2.4.2. Vibration sense

Vibration sense was measured by using a 128 Hz tuning fork. The vibration test was carried out on the middle or upper sternum, the radial side of both wrists and the fibular side of both ankles. Subjects were told to indicate when they no longer could feel the vibrations. The examiner simultaneously struck a tuning fork and started a stopwatch, then placed the base of the fork against the area to be tested. The time interval until the subject reacted was recorded.

2.4.3. Position sense

The testing of position sense was carried out on subjects with their eyes closed. A ruler with a millimeter scale was used. Tests were carried out on the subject's index fingers and big toes. A ruler was placed vertically alongside the digit. With the digit held horizontally, the zero point was the position of the digit's nail on the ruler's scale. The examiner held the digit by its sides and moved it either up or down, holding the position for about 1 s. The subject was asked to indicate whether they felt the movement and if it was up or down. The upward or downward movement started from 5 mm from the zero point and was considered to be the minimum value. The movement was increased in 5 mm increments and the subject's threshold distance was recorded.

Each trial was carried out once for each distance except when the subject was uncertain. In that case the examiner would repeat the test again for an odd number of times and choose the dominant response. If the subject could not feel the maximum movement, the threshold was defined as the maximum distance plus 5 mm.

2.4.4. Two-point discrimination

The two-point discrimination test was carried out on subjects while their eyes were closed. A drafting divider, with the legs set at different distances, was pressed against the subject's skin at an angle of 30 to 45° to a depth of between 1 and 2 mm for about 1 s. The distances between the points used in the test were 1, 2, 3, 4, 5, 6, 8, 10, 12, 15, 20, 25, 30 and 36 mm. The threshold recorded was the shortest distance at which a subject answered correctly. This method was performed on the lower lip and the ventral side of each index finger. If the subject was unable to detect the maximum distance of 36 mm, the threshold was defined as 40 mm for calculation purposes.

In testing Groups CO and CY, the "Yes/No" method was used. However, when a subject felt that 1-point stimulation was actually 2-point stimulation, they were re-tested using the "2-alternative, forced-choice method". In Groups JE and JC the "2-alternative, forced-choice method" was used exclusively.

2.5. Statistical methods

All the calculations were performed using MS Excel and SPSS. Chi square analysis was used in MS Excel when the prevalence was compared, and t-test was used in MS Excel when the average was compared. The correlations were calculated by SPSS.

When we calculated the minimal tactile sense, we converted the grams to the evaluator size using the equation: Evaluator size = log([gram]) + 4.

3. Results

3.1. The subjects' backgrounds

The age and sex of the subjects are shown in Table 1. The age and sex in Groups CO, JC and JE were not statistically different. The age of Group CY was less than the other groups.

From Table 2, we can see that 86% of Group CO and 83% of Group CY answered the question on how they obtained fish and over 60% of Groups CO and CY answered that they are catching fish by themselves. Also from Table 2, we can see that 41% of Group JE and 1% of Group JC

2508
025

Table 1
Age and sex of each group.

	Age	n (M/F)
Group CO	57.5 ± 8.1	44 (19/25)
Group CY	34.4 ± 9.5	36 (18/18)
Group JE	59.0 ± 7.5	88 (38/50)
Group JC	58.4 ± 11.6	164 (67/97)

belonged to a fisher family. Ninety-three percent of Group JE and 25% of Group JC ate fish every day.

Table 3 shows the relevant medical history of Group CO and Group CY. The information was collected through interviews. On the question of hypertension, although some subjects had no recorded history of hypertension, high blood pressure was detected during the tests. If we detected a systolic pressure of 170 or more or and diastolic pressure of 110 or more in a subject, we recorded that hypertension was present. Some neurological or neurologically related diseases were found in 47 subjects (53%) of Group JE. No neurological or neurologically related diseases were found in Group JC.

3.2. Questionnaire on medical complaints

Medical complaints reported from each group are shown in Table 4, and the p-values by chi square among the four groups are shown in Table 5. In general, the prevalence in both "Yes, always" and "Yes, always" + "Yes, sometimes" in Groups JE, CO, and CY was statistically higher than Group JC. In general, the prevalence in Group JE and Group CO was similar. For most of the complaints Group CY showed a lower prevalence than Group CO.

The questionnaire consisted of questions related to specific and non-specific symptoms in the methylmercury polluted area. Specific symptoms included numbness, difficulty in speaking, fine-finger tasks, buttoning, losing slippers while walking, difficulty in differentiating tastes, detecting smells etc. Non-specific symptoms included headaches, forgetfulness, general fatigue, and so on. In specific symptoms, the prevalence of the answer "Yes, always" + "Yes, sometimes" was lower in Table 4. A tendency to a similar prevalence was observed both in specific and non-specific symptoms.

The correlation efficient among four groups was shown in Table 7. In "Yes, always" answers, the correlation between Groups JE and CO was highest, and was followed by the one between Groups CO and CY. In "Yes, always" + "Yes, sometimes" answers the correlation between Groups CO and CY was highest, and was followed by the one between Groups JE and CO and between Groups JE and CY.

Table 2
Fish sources and frequency of ingestion.

In Canada	Group CO	Group CY
Self-caught fish	28/44 (64%)	24/36 (67%)
Fish caught by relatives and friends, purchased etc.	30/44 (68%)	22/36 (61%)
A combination of both the above	38/44 (86%)	30/36 (83%)
In Japan	**Group JE**	**Group JC**
Fishermen	10/88 (11%)	0/164 (0%)
Fishermen's families	36/88 (41%)	1/164 (1%)
Sport fishing/recreational fishing	62/88 (70%)	17/161 (11%)[b]
Daily ingestion	81/87 (93%)[a]	40/157 (25%)[c]
Ingestion more than once a week	85/87 (98%)[a]	119/157 (76%)[c]

[a] Datum for 1 person was missing.
[b] Data for 3 persons were missing.
[c] Data for 7 persons were missing.

Table 3
Complications in Canadian subjects.

	Group CO	Group CY
Hypertension	15 (34%)	16 (44%)
Diabetes mellitus	8 (18%)	3 (8%)
Stroke	3 (7%)	1 (3%)
Lung diseases	0 (0%)	1 (3%)
Stomach diseases	6 (14%)	1 (3%)
Heart diseases	1 (2%)	0 (0%)
Orthopedic diseases	7 (16%)	4 (11%)
Psychiatric diseases	3 (7%)	1 (3%)

3.3. Neurological examination

The neurological findings for each group and p-values by chi-square among the four groups are shown in Table 6. The prevalence was generally highest in Group JE, and the prevalence of all the findings of Groups JE and CO was statistically higher than Group JC. All the findings of Group CY were less prevalent than Group CO, and seven of twelve findings of Group CO showed statistically higher prevalence than Group CY.

The most prevalent findings in Groups CO are tandem gait abnormality and somatosensory disturbances of pain and touch, followed by hearing impairment, truncal ataxia other than tandem gait abnormality, upper extremity ataxia (finger–nose test and diadochokinesis), and lower extremity ataxia (heel–shin test). The prevalence of visual constriction or dysarthria was lower. Although the orders of prevalence for the positive findings were different, the tendencies of the abnormalities were similar between Groups CO and JE.

Correlation among four groups was shown in Table 7. Correlations between Groups JE and CY, Groups CO and CY, and Groups JE and CO were higher than those between Group JC and other three groups, and p-values were lower.

3.4. Quantitative sensory measurements

3.4.1. Minimal tactile sensitivity using the Semmes–Weinstein monofilament test

Thirty-three subjects (75%) of Group CO and 24 subjects (67%) of Group CY were examined. One set of data for the lower lip in Group CO and one set of data for the left and right big toes in Group CY were absent. 84 of 88 subjects (95%) in Group JE (in which three sets of data were missing for the lower lip) and all 164 subjects of Group JC were examined and calculated.

Fig. 1 shows the results of the minimal tactile sensitivity using the Semmes–Weinstein monofilament test. The results were worst in Group CO, and there were distinct statistical differences between Groups CO, CY, and JC. Group JE was, in general, positioned between Groups CO and CY.

3.4.2. Vibration sense

Thirty-five subjects from Group CO and 25 subjects from Group CY were examined. Two subjects from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 33 subjects (75%) from Group CO and 24 subjects (67%) from Group CY were used in the calculation. Three sets of data for the right ankle and 4 sets of data for the left ankle were absent for Group CO. All 88 subjects of Group JE and all 164 subjects of Group JC (in which one set of data for the chest and one set of data for the left and right ankles were absent) were examined and calculated.

Fig. 2 shows that the vibration sense was worst in Group JE, followed by Group CO, Group CY and Group JC. Most of them had statistical differences between each other.

35	General fatigue	40%	31%	45%	2%	95%	78%	87%	25%

3.4.3. Position sense

Twenty-eight subjects from Group CO and 24 subjects from Group CY were examined. One subject from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 27 subjects (61%) from Group CO and 23 subjects (64%) from Group CY were used in the calculation. One set of data for the left and the right big toe, both upward and downward movements, was absent for Group CO. Eighty-seven subjects from Group JE (in which one set of data for both big toes in both directions was absent) and all 164 subjects of Group JC were examined and calculated.

Fig. 3 shows that the position sense was worst in Group JE, followed by Group CO, Group CY, and Group JC. Although there were some exceptions, most of the groups had statistical differences.

3.4.4. Two-point discrimination

Thirty-four subjects from Group CO and 25 subjects from Group CY were examined. Two subjects from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 32 subjects (73%) from Group CO and 24 subjects (67%) from Group CY were used in the calculation. 87 of 88 subjects (99%) from Group JE and all 164 subjects of Group JC (in which one set of data for the right index finger was absent) were examined and calculated.

Fig. 4 shows that the position sense was worst in Group JE or Group CO, followed by Group CY and finally Group JC. Most of them had statistical differences, except for the results for index fingers when comparing Group JE with Group CO.

4. Discussion

Our results show that subjective complaints were most prevalent in Group JE, followed by Groups CO, CY and JC. Similar and high prevalence of more specific complaints from methylmercury poisoning between Groups JE and CO suggest that these similarities are mainly related to methylmercury poisoning. The increase of non-specific complaints, which was found in Group JE, was also observed in Group CO.

The high prevalence of somatosensory disturbance and following ataxic movement in Groups JE and CO suggests that those two groups are similarly affected by methylmercury and Group CY is affected to a smaller extent by methylmercury. Harada et al. (1976) conducted health surveys on 89 indigenous inhabitants of Grassy Narrows and Whitedog and found sensory disturbance (47.6%), abnormality in visual field (18.0%), impaired hearing (44.9%), ataxia (9.0%), and dysarthria (5.6%). These findings together with the Hunter–Russell syndrome suggest methylmercury pollution in these communities.

Except for the high prevalence of tandem gait abnormality and hearing loss, the pattern of prevalence is almost the same as our study from the Minamata area in the 1970s (Fujino, 1994). Harada and his colleague visited Grassy Narrows in 2002 (Harada et al., 2005a) and Grassy Narrows and Whitedog in 2004 (Harada et al., 2005b). In 2002, glove and stocking type of sensory disturbance (54.4%), tunnel vision (10.5%), ataxia (12.3%) and impaired speech (12.3%) were observed in 57 subjects (Harada et al., 2005a). Combining the results of both studies, 2002 and 2004, glove and stocking type sensory disturbance was found in 65.1% of the cases, tunnel vision in 10.8%, ataxia in 25.1% and impaired speech in 6.9% of the 175 subjects (Harada et al., 2005b). As the criteria used for determining ataxia was not described in those papers, it is possible that the actual percentage could be greater than the papers suggested. We show the raw data for ataxic movement in this study.

Our present study differs from the former studies of 1975, 2002 and 2004, in that quantitative measurements of somatosensory disturbance were added to the study. The results of two-point discrimination sensitivity of the lower lip, vibration sense and position sense in big toes were also worse in Group JE, followed by Groups CO, CY and JC. Somatosensory acuity was most impaired in Group JE. Whereas minimal tactile sensitivity of the lower lip and left big toe were worst in Group CO, followed by Groups JE, CY and JC. The reason for these differences is, as yet, unascertained. As to two-point discrimination, the "Yes/No" method was used in testing Groups CO and CY, and the "2-alternative, forced-choice method" was used in testing of Groups JE and JC. But, in our experience, there were no great differences between results of these two methods.

Quantitative measurements showed that somatosensory disturbance, showing a similar pattern, was present in all tested body areas. These patterns are assumed to be the characteristics of somatosensory disturbance due to a uniformly injured central nervous system, especially the sensory cortex.

The similarity in the symptoms of abnormalities, neurological findings and quantitative measurements in Groups JE and CO were assumed to be produced by methylmercury poisoning. The intermediate abnormalities in Group CY suggest a milder and continuing effect of methylmercury poisoning in the younger generations of this area.

There are some limitations in this study. The first one is that the subjects in the study consisted of applicants who volunteered for the examination. The subjects in Groups JE, CO and CY ate a lot of fish, but the subjects in Group JC ate less fish. Also the lifestyle and occupations of the Japanese and the Canadian subjects are likely to be quite different. Also, the lifestyle and occupations were not the same in the two Japanese groups JE and JC.

Secondly we had no control area in Canada. Instead, we compared the Canadian results with the results from a control area in Japan, as well as from an exposed area in Japan.

Thirdly, there can be other factors involved which can affect the findings. In Groups CO and CY, some neurological diseases were found which confused the analysis of the test results. In order to overcome this limitation, we tried to compare a wide range of symptoms and complaints, neurological findings and quantitative measurements.

In the earlier study in Japan, we found that some complaints, symptoms, neurological findings, and quantitative measurements recorded could be affected by the presence of certain other neurological diseases. However, the similar patterns of symptoms, neurological findings, and quantitative sensory measurements cannot be explained without taking

into account the possibility of the presence of methylmercury poisoning (Takaoka et al., 2008).

After Harada's paper in 1976, the health effects of methylmercury on indigenous Canadians (First Nations) were reported by Canadian researchers. Barbeau et al. (1976) reported that he discovered symptoms like Minamata disease patients in Quebec, but he soon modified and toned down his conclusions. Shephard (1979) admitted the higher exposure in Canadian Indians and insisted that there was no agreement on the clinical diagnosis of mercury poisoning. But no conclusive human health-related data of Canadian Indians were presented by them. Wheatley et al. (1979) reported that they failed to prove abnormalities attributable to methylmercury. But his study in 1979 was based on clinical and pathological test results taken from only one male Cree Indian.

In north-western Quebec, McKeown-Eyssen and Ruedy (1983) studied individuals from the Cree First Nation and reported incoordination (15.4% in males/6.5% in females in Mistassini, 44.2% in males/26.5% in females in Great Whale), abnormal perception of sensations (5.7% in males/4.3% in females in Mistassini, 9.3% in males/2.1% in females in Great Whale). The results for subjects who had visual field scores of over 55° were 16.0% in males and 19.4% in females in Mistassini, and 0.7% in males and 15.5% in females in Great Whale. Although the patterns of abnormalities are very different from our results, the presence of these abnormalities could suggest milder methylmercury poisoning. The Canadian researchers did not, however, come to this conclusion. It would appear that they did not follow up and observe the individuals for a longer period of time, which is unfortunate. In our new Minamata disease cases, observed from November 2004 to April 2005, about half of them were considered to have had their first abnormalities after 1968, the year when the Chisso Company ceased to release methylmercury contaminated industrial wastewater (Takaoka et al., 2009).

Spitzer et al. (1988) found no abnormalities in north-western Quebec when they compared people from the Cree First Nation with a control group. In this study, the exposed group (SDD: The Self Designated Disease Group) and other three control groups were compared. Visual constriction was observed in 4.9% of SDD and in 0.0–1.7% of other groups. Peripheral sensory disturbance (written as "peripheral neuropathy" in the paper) was observed in 9.9% of SDD and in 1.5–3.1% of other groups. There was a higher tendency in the prevalence in SDD, but there was no statistical difference between SDD and other groups.

In examining the Cree people, McKeown-Eyssen et al. (1990) emphasized inter-observer variation. It is more important, however, to do the same examination in the control area and to set criteria for judging the results of the examination, rather than to repeat an examination in the same group. Even though there were some variations and differences between the results obtained by the screener and the results of the neurological examination by the neurologist, e.g. prevalence of tremor (screener 40.2%, neurologist 29.9%) and incoordination (screener 22.8%, neurologist 15.4%) in men in Mistassini, they were still high. They also had differences in criteria when identifying neurological abnormalities, but it should be possible to set standard criteria for the assessment of the neurological findings similar to our methods.

Changeability of neurological functions is quite common in cases of Minamata disease. In Minamata disease the range of four limb

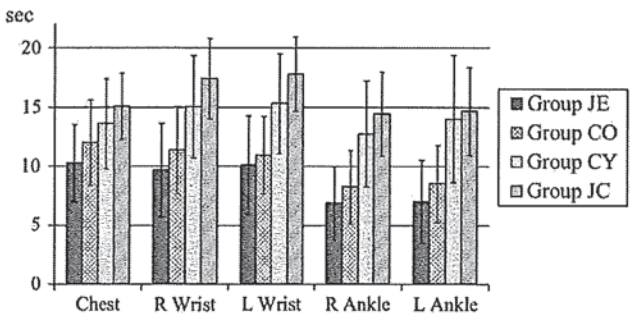

Fig. 2. Threshold for vibration sense — group comparisons. somatosensory disturbance is changeable. Uchino and Araki (1984) reported on 100 cases of Minamata disease. In 77 of the 100 cases the examination for superficial sensory disturbance was carried out from 2 to 5 times, and 63 of the 77 cases (82%) were recorded as "unstable type" in which the area of the body showing somatosensory disturbance changed. The most important factor in showing the effect of environmental pollution on the inhabitants of an area is the ability to gather data and information from both the people exposed to the pollution and from a control group which has not been exposed.

There are some other Canadian studies about the exposure to methylmercury (Wheatley and Paradis, 1996; Wheatley et al., 1997; Wheatley and Paradis, 1998), but there are few that take into account epidemiological human health data. Wheatley (1996) stressed that the people of the First Nations understanding of mercury contamination is influenced by their holistic concepts of health and environment. But there was too little physical data available to corroborate this concept. Without the presence of human physical data, we cannot evaluate psychological, social and spiritual values of health.

5. Conclusions

The data collected from methylmercury-exposed indigenous residents of Grassy Narrows suggest that they were poisoned by methylmercury. The health abnormalities also appear to exist in a milder form in the younger generations from Grassy Narrows.

Information on funding sources

The study was conducted partly with funding from Grants-in-Aid for Scientific Research of Japan Society for the Promotion of Science (JSPS) (No. 20330118). The title of the funding is "Studies on the reappraisal of the real situation of Minamata disease damages and their social impact in the past half-century."

Conflict of interest

There is no conflict of interest in this study.

Acknowledgment

We, the authors, would like to express our thanks to the late Masazumi Harada of the Open Research Center for Minamata Studies, Kumamoto Gakuen University, for his planning and involvement in carrying out this research, by dedicating this paper to his memory.

Education・Work Experience

March	1968	Graduated from Kumamoto University Medical School
April	1969	Entered Department of Neuropsychiatry, Faculty of Life Sciences, Kumamoto University
April	1972	Minamata Sanatorium Post-graduate student, Department of Neuropsychiatry, Faculty of Life Sciences, Kumamoto University
January	1974	Director, Yoshikazu Medical Institution, Minamata Clinic
April	1976	Post-graduate student, Institute of Constitutional Medicine, Kumamoto University
March	1978	Director, Yoshikazu Medical Institution, Minamata Kyoritsu Hospital
February	1981	Received Medical Degree (Kumamoto University, Doctor No. 399)
March	1982	Completed post-graduate programs at Kumamoto University Medical School and the Institute of Constitutional Medicine
April	1989	Contract Psychiatrist, Minamata Public Health Center, Kumamoto Prefecture, up to March 2002
April	1990	General Director, Yoshikazukai Medical Institution, Minamata Kyoritsu Hospital Director, Minamata Kyoritsu Neurology and Rehabilitation Clinic
July	2002	Tomiokai Medical Institution, Sakuragaoka Hospital
January	2005	Forensic Psychiatrist, Kumamoto District Court, up to December 2008
April	2006	Visiting Researcher, Open Research Center for Minamata Studies, Kumamoto Gakuen University
July	2008	Yoshikazukai Medical Institution, Kikuyo Hospital
April	2009	Yoshikazukai Medical Institution, Minamata Kyoritsu Hospital
April	2012	Anninkai General Foundation, Kumamoto Seimyo Hospital

Clinical research experience in Canada

August	1975	Participation in G.N. and W.D. medical screening, with Dr. Masazumi Harada
August	2002	Participation in G.N. medical screening, with Dr. Masazumi Harada
August	2004	Participation in G.N. and W.D. medical screening, with Dr. Masazumi Harada

Education

1973 Graduated Faculty of Medicine, Kumamoto University

1973 Started work at Department of Neuropsychiatry, Faculty of Life Sciences, Kumamoto University

1975 Tomiai Prefectural Hospital Kumamoto (currently called Kokoro Medical Center)

1977 Research Associate, Poisoning Research Center, Neurotoxin Sector, Kumamoto University

1981 Research Associate, Department of Psychiatry, Kumamoto University

1987 Chief Psychiatrist, Okinawa Miyako Hospital

1989 Lecturer, Department of Neuropsychiatry, Kumamoto University

1997 Associate Professor, Department of Neuropsychiatry (Clinical Psychology), Kumamoto University

2004 Associate Professor, Department of Psychiatry and Neuropathology, Graduate School of Medicine and Faculty of Medicine of Kumamoto University (Chief Psychiatrist, Department of Neuropsychiatry)

2005 Professor, Graduate School and Faculty of Social Welfare of Kumamoto Gakuen University (Welfare Environmental Studies)

Clinical research experience in in Canada

August 2014 Participated in clinical research in Grassy Narrows and Whitedog

付録 **A: 2014** 年に書かれた記事 – カナダ・オンタリオ州北西部に位置する北米先住民族コミュニティーにおけるメチル水銀汚染の兆候と症状 11
付録 **B:** 著者の履歴書 20

前書き：専門分野と資格

私たちは日本の九州に位置する熊本県の 3 人の医師です。下記の内容は私たちの経験と専門分野の簡潔な要約です。

高岡滋医師：私は医師で日本国熊本県水俣市にある神経内科リハビリテーション協立クリニックの院長です。私の専門は幅広く、神経内科とリハビリテーションそして一般内科です。私は日本の水俣市とカナダ国オンタリオ州グラッシーナローズにて水銀汚染されたと疑われる患者の住民健診に参加しました。グラッシー・ナローズにおいては原田正純医師率いる調査チームに参加しました。臨床経験に加え、私は水銀汚染に関する論文をいくつか共同で執筆し、それらは論文審査のある医学科学専門誌で発表されました。

藤野糺医師：私は熊本病院で精神科と神経内科を専門としている医師です。私は日本の水俣において水銀汚染された患者の住民健診の経験が豊富であります。数十年に渡り、何度も原田正純医師率いる調査チームと共にカナダ国オンタリオ州グラッシー・ナローズで水銀汚染されたと疑われる男性女性児童の住民検診を多く手がけました。両国において臨床研究について広範囲にわたり論文を執筆し、それらは論文審査のある多くの医学科学専門誌で発表されました。

下地明友医師：私は神経精神科医であり、熊本大学の教授でもあります。故原田正純医師率いる調査チームと共にカナダ国オンタリオ州グラッシー・ナローズにおいて水銀汚染された又は水銀汚染が疑われた患者の臨床評価に参加しました。日本における臨床経験に基づき、私は水銀汚染に関する論文を執筆・共同執筆し、それらは論文審査のある医学科学専門誌で発表されました。

私たちの履歴書は専門家報告書の付録 B に記載されています。

専門的意見を依頼された経緯と背景

私たちはグラッシー・ナローズ・ファースト・ネーションを代理であるカナダ環境法協会のジョゼフ・F・カストリリ氏とリチャード・D・リンドグレン氏より下記の 4 つの質問に回答として専門家報告書の作成を依頼されました。質問の中に出てくる参照ページは原告の申請記録「グラッシー・ナローズ・ファースト・ネーション及びその他、対オンタリオ州天然資源省森林局及びその他」から引用しています。

Questions for Dr. Shigeru Takaoka et al.	高岡滋医師とそのチームにへの質問	
English	**日本語**	**関連ページ**
Question 1: Based on the clinical medical examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on the statements, which appear below respecting pages 001251 to 001252 of the January 2014 request by Grassy Narrows (GN) to the Government of Ontario, and whether they are accurate in their summary of the findings of Dr. Harada's team based on the two Harada referenced reports of 2005 and 2011 that appear at page 001284 of the January 2014 request?	**質問１：原田医師とそのチームがグラッシー・ナローズで長年に渡って行った臨床医療調査をもとに、下記のステートメントにコメントしてください。2014 年 1 月にオンタリオ州政府へグラッシー・ナローズから提出されたリクエストの 001251 ページから 001252 ページに関連しています。それらは 2014 年 1 月のリクエストの 001284 ページに記載されている、原田医師が書いた 2005 年と 2011 年の報告書に基づいて原田医師のチームが出した調査結果はその要旨において正確でしょうか。**	
Excerpt from: Bump-up Request for an Individual Environmental Assessment (IEA) submitted to the Ontario Ministry of the Environment regarding the Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022 - Final Plan Inspection Approved by the Ministry of Natural Resources, December 23, 2013 - EBR Registry No. 010-9240 Submitted by: Grassy Narrows First Nation and Earthroots January 22, 2014 5. Mercury Impacts Human Health in Grassy Narrows SUMMARY 35 Years of study by renowned mercury expert Dr. Harada and his team have confirmed that people in Grassy Narrows are suffering from Minamata Disease as a result of methyl mercury ingested by eating local fish. EVIDENCE Doctor Harada's teams of researchers have studied mercury health impacts in Grassy Narrows for over 35 years starting in 1975. "[I]t is an undoubtable fact that Minamata Disease occurred in [Grassy Narrows and White Dog], based on our long-term investigation result." (Harada et al., 2011) Grassy Narrows people "were poisoned by eating fish contaminated with mercury." (Harada et al., 2011) Findings by Harada et al., 2011	次より抜粋：2012 年 4 月 1 日から 2022 年 3 月 31 日までの 10 年間に及ぶウィスキー・ジャック・フォレストの森林管理計画に関してオンタリオ州環境省に提出された個別環境調査(IEA)への再リクエスト– オンタリオ州天然資源省より 2013 年 12 月 23 日に承認された最終計画監査。EBR Registry No. 010-9240 2014 年 1 月 22 日にグラッシー・ナローズ ファーストネーションとアースルートにより提出。 ５．グラッシー・ナローズにおいての水銀の人間の健康への影響 要旨 水銀の専門家として有名な原田医師とそのチームによって行われた 35 年に及ぶ調査により、グラッシー・ナローズ住民は地元で採れた魚を食することによって摂取したメチル水銀が原因で水俣病に苦しんでいることが確認された。 証拠 原田医師の研究者チームは 1975 年以来 35 年に渡りグラッシー・ナローズにおいて水銀の健康に対する影響を調査した。 「長期間に及ぶ調査の結果、（グラッシー・ナローズとホワイト・ドッグでは）水俣病が発生したことは疑う余地のない事実である。」（原田医師とそのチーム、2011 年） グラッシー・ナローズの人々は「水銀に汚染された魚を摂取することにより汚染された。」（原田医師とそのチーム、2011 年） 原田医師とそのチームによって発見された事実	1251-1252

• 59% of the 160 people tested in GN and White Dog were affected by mercury. • 34% were diagnosed with Minamata Disease (MD) using current Japanese diagnostic criteria (41% in GN --> 30 cases) • 25% were diagnosed with suspected Minamata Disease (SMD) • 44% of people aged 21-40 had MD or SMD. All these people were born after the mercury dumping was curtailed in 1971. "[T]he possibility of congenital Minamata Disease occurrence is very high in these two communities. We examined 7 cases of cerebral palsy and 7 cases of mental deficiency…. Further epidemiological research on stillbirths and miscarriages needs to be done." (Harada et al., 2005) All of Dr. Harada's patients who indicated mercury levels higher than the safetyguideline of 50 ppm in 1975 were deceased by 2004. (Harada et al., 2005)	(2011 年) • グラッシー・ナローズとホワイト・ドッグで検査を受けた 160 名の 59%が水銀に汚染されていた。 • 現在の日本の診断基準に基づき、34%が水俣病（MD）と診断された。（グラッシー・ナローズでは 41%、30 件以上） • 25%は水俣病の疑いあり（SMD）と診断された。 • 21 歳か 40 歳の 44%が MD 又は SMD と診断された。全員が 1971 年に水銀放出が削減された以降に生まれている。 「これらの２つのコミュニティーにおいて先天的水俣病発生率は極めて高い。脳性まひ 7 症例と知的障害 7 症例を調査した。死産と流産に関しては、より詳しい疫学的調査を実施する必要がある。」（原田医師とそのチーム、2005 年） 原田医師の患者全員で、1975 年には水銀レベルが 50 ppm の安全指針よりも高かったが、2004 年までには下がった。（原田医師とそのチーム、2005 年）

Question 2: Based on the clinical medical examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on the statements, which appear below respecting pages 001445, 001479 to 001483 of the September 2014 supplementary GN submissions to the Government of Ontario, and whether they are accurate in their summary of the findings of Dr. Harada's team referred to in those pages?	**質問２：原田医師とそのチームがグラッシー・ナローズで長年に渡って行った臨床医療調査をもとに、下記のステートメントにコメントしてください。2014 年 9 月にグラッシー・ナローズがオンタリオ州政府に提出した補足提出の 001445 ページ、 001479 ページと 001483 ページに関連しています。それらは原田医師のチームがこれらのページおいて言及している調査結果はその要旨において正確でしょうか？**	

The following 5 Excerpts are from: Literature Review regarding the Impact of Mercury on Human Health Summary of a text produced by Drs. Laurie Chan and Donna Mergler for the Mercury Disability Board presented by Donna Mergler PhD, Professor Emerita, University of Quebec at Montreal: Dr. Harada's studies • Dr. Harada did pioneering work in Japan, demonstrating neurologic damage of Minamata Disease • In a recent report, he stated: "During the early stages of the MD crisis in Minamata, patients, who were diagnosed with MD, seemed to be typical and severe cases of the Hunter-Russell syndrome, including sensory disturbance, concentric constriction of the visual field, ataxia, speech impairment and impaired hearing. However, through more study, it became clear that such severe cases were rather exceptional and many more mild cases were progressing to chronic Minamata Disease. I observed that the symptoms of Minamata Disease became more chronic and atypical in the 1970s. Also I have been proving that sensory disturbances, specifically stronger loss of sensation in the extremities, were seen among patients of methylmercury poisoning at a very high rate, through clinical examinations on family members of patients with sever(sic) and typical symptoms or mothers of congenital Minamata Disease patients"	下記の 5 つは次からの抜粋です。人間の健康に及ぼす水銀の影響に関する文献の考察 ローリー・チャン博士とドナ・マーグラー博士により水銀障害委員会のために作成された文章の要旨 モントリオール、ケベック大学名誉教授ドナ・マーグラー博士によって公開されました。 原田医師の調査 • 原田医師は日本で草分け的な調査を行い、水俣病の神経系の障害を証明した。 • 最近の報告書にて、彼は「水俣市における水俣病騒動の初期において、水俣病患者は知覚障害、視野の求心性収縮、運動失調、発語障害と聴覚障害などの、ハンター＝ラッセル症候群患者に典型的でかつ重度な症状が見受けられた。しかしながら、より多くの調査を通じて、そのような重度な症例はどちらかというと例外的で、多くの軽症例が慢性的水俣病へ移行していくことが明確になった。水俣病の症状は 1970 年代に、より慢性で変則的なものとなったことが認められ。また私は、先天性水俣病患者の家族または母親の臨床検査を通じて、知覚障害、厳密に言えば、四肢におけるより強度な知覚喪失がメタル水銀中毒患者に非常に高い率で診られることを証明した。」と述べている。	1479
Dr. Harada's studies • In the '70s, he showed that persons in Grassy Narrows and White Dog manifested similar signs and symptoms to MD and there appeared to be a dose-relation with mercury exposure • In 2002 and 2004, he and his team went back. In total they examined 156 people from Grassy Narrows and White Dog. • Age ranged from 1-90 years • No information was provided on how persons were recruited	原田医師の調査 • 70 年代に、彼はグラッシー・ナローズとホワイト・ドッグの住人に水俣病に似た兆候と症状が現われ、水銀の摂取量と関係があることを明らかにした。 • 2002 年と 2004 年に彼と彼のチームは現地へ戻り、グラッシー・ナローズとホワイト・ドッグで合計 156 名を調査した。 ・年齢は 1 歳から 90 歳 ・調査対象の選出法については一切公表されていない	1480

Dr. Harada's studies • Diagnostic criteria: • MD: more than one symptom of: sensory disturbances, ataxia, disturbed ocular movement, imbalance, concentric constr[i]ction of the visual field and speech impairment. • In cases where examinees were showing only sensory disturbances, we acknowledged MD as long as there was no other disease causing the symptom. • If an examinee had another disease and still showed symptoms of MD that were not explained by that other disease, we defined the case as MD with complications.	原田医師の調査 ・診断基準 • 水俣病：知覚障害、運動失調、眼球運動障害、平衡失調、視野の求心性収縮、発語障害の症状のいずれかが一つ以上認められる。 • 調査対象で知覚障害のみが認められた場合、その症状を引き起こす他の疾患が認められない場合は水俣病と認識した。 • 調査対象が他の疾患を持ちながら水俣病症状を表し、その症状が他の疾患によるものではない場合、そのケースは合併症を伴う水俣病とした。	1481
Dr. Harada's studies • Findings: • 60 cases of MD (34.2% of total examinees, excluding people 10 years old and younger); • 54 cases (30.8%) of MD with complications; • 25 cases (14.2%) of possible MD for a total of 139 cases (79.4%). • They conclude : • It is very high rate of neurological symptoms for a sample of a population, even though examinees came because of other health issues. It is as high as contaminated areas in Minamata. We cannot help but recognize the effects of methylmercury from the symptoms we have seen.	原田医師の調査 ・調査結果 ・60 の症例が水俣病（調査対象全員の 34.2%、10 歳以下を除く） ・54 の症例（30.8%）が合併症を伴う水俣病 ・合計 139 の症例（79.4%）のうち 25 の症例（14.2%）が水俣病の疑いがある ・結論 ・調査対象が他の健康問題で来たにもかかわらず、住民の実例としては神経症状はかなり高い率で見られた。それは水俣の汚染地域と同じくらい高かった。我々が見た症状からするとメチル水銀の影響と認識せざるを得ない。	1482
Our conclusions [of Drs. Chan and Megler] • Dr Harada and his group did not evaluate the prevalence of MD in this population, but reported on the percentage of MD signs and symptoms within the group that they examined. • We consider that Dr. Harada's follow-up clinical evaluation should be seen as a preliminary study showing the need for a comprehensive epidemiologic study that would include all of the known outcomes of mercury exposure and could take into account co-morbidity from other diseases, such as diabetes and /or alcohol and test for possible interactions. Such a study should also take into account the presence of other contaminants. For this study it would be most useful to have all of the results of hair and blood sampling by Health Canada, Dr. Chan and Dr. Harada, as well as the results of the neurological examinations that were done by Dr. Harada.	我々の結論（チャン博士とメグラー博士による） • 原田医師と彼のチームはこの住人における水俣病の患者数は見積もらなかったが、水俣病の兆候と症状を示した調査対象人数の参加人数に対するパーセンテージを報告した。 • 原田医師のフォローアップ臨床評価は、既に知られていた水銀汚染の全ての結果を含む、包括的な疫学調査の必要性を示す予備調査として見られるべきであり、糖尿病やアルコールとの相互作用の可能性のテスト等、他の疾患との合計疾患率を考慮せねばならない。このような調査は他の汚染物質の存在をも考慮せねばならない。この調査のためにはヘルス・カナダやチャン博士と原田医師による髪の毛や血液のサンプル摂取の結果の全てと原田医師によって実施された神経学に関する調査の結果があれば最も価値あるものとなるであろう。	1483

Question 3: Based on the clinical psychological/psychiatric examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on whether you agree with the statements of Donnan, 1986, regarding the psychological health impacts of mercury/methylmercury, which statements appear below respecting pages 001492 to 001493 of the November 2014 supplementary GN submissions to the Government of Ontario? In your professional opinion, has exposure to mercury had psychological/psychiatric impacts on the people of Grassy Narrows and, if so, what have been those impacts?	**質問３：原田医師とそのチームがグラッシー・ナローズで長年に渡って行った臨床心理学的・精神学的調査をもとに、1986 年にドナンが述べた、水銀・メチル水銀の心理学的健康の影響について下記のステートメントに貴殿が同意するか否かをコメントしてください。2014 年 11 月にグラッシー・ナローズがオンタリオ州政府に提出した補足提出の 001492 ページと 001493 ページ関連しています。専門家として貴殿は、グラッシー・ナローズの住人は水銀汚染されたことによって心理的・精神的影響を受けたでしょうか。受けたとお考えであれば、どのような影響を受けたのでしょうか。**	
Excerpts from: Grassy Narrows and Earthroots Fourth Supplementary Submission to Devon Wills, Ministry of the Environment on 2012-2022 Whiskey Jack Forest Management Plan IEA Request, dated November 14, 2014 2. PSYCHOLOGICAL HEALTH IMPACTS OF MERCURY "High blood mercury levels contribute to anxiety..." (Donnan, MOE 1986, p.28) "…mental health effects such as anxiety due to mercury contamination in the Wabigoon-English River System have been borne almost entirely by the Native people of the Grassy Narrows and Whitedog Bands." (Donnan, MOE 1986, p.28) The fear and anxiety from knowing they were contaminated was debilitating to many. The threat of mercury poisoning clearly affected the mental health of these people…." (Donnan, MOE 1986, p.31) "[A] reduction in fish mercury levels could help to reduce anxiety and mental trauma experienced by these people." (Donnan, MOE 1986, p.44)	次から抜粋：グラッシー・ナローズとアースルーツの 2012-2022 年ウィスキージャック森林管理計画 IEA リクエストに関する、デボンウィルス、環境省に提出した第４補足提案、2014 年 11 月 14 日付 ２．水銀の心理学的健康への影響 「高い血中の水銀値は不安を抱かせる」（ドナン、MOE 1986 年、28 ページ） 「グラッシー・ナローズとホワイトドッグ・バンドの原住民によってほぼ全域が所有されているワビゴーン-イングリッシュ川沿岸が水銀に汚染されていることによって引き起こされる不安などのメンタルヘルスの影響」（ドナン、MOE 1986 年、28 ページ） 「彼らが汚染されていると知っていることによる恐れと不安は、多くの人々を衰弱させる。水銀汚染の脅威は明らかにこれらの人々のメンタルヘルスに影響を及ぼしている。」（ドナン、MOE 1986 年、31 ページ） 「魚の水銀汚染レベルを下げることは人々の不安と彼らが経験した精神的なトラウマを少なくさせることに役立つ。」（ドナン、MOE 1986 年、44 ページ）	1492-1493
Question 4: Do you continue to adopt the findings and conclusions contained in the article by Shigeru Takaoka, et al, entitled "Signs and symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" reported in Science of the Total Environment 468-469 (2014) 950-957? If not, what has caused you to change your opinion since publication of the article?	**質問４：高岡滋医師と彼のチームによって書かれ、Science of Total Environment 486-469 (2014) 950-957 に報告された「カナダ・オンタリオ州北西部にあるファーストネーション・コミュニティーにおけるメタル水銀汚染の兆候と症状」という題名の記事に記載されている調査結果と結論を引き続き支持されますか。支持ないのであれば、この記事が発表となって以来どのような理由で貴殿のご意見が変わったのでしょうか？**	

質問への回答

質問１

正確です。

質問２

正確です。

質問３

我々専門家の意見では、精神的悪影響を受けました。

質問４

我々は引き続き支持します。

HIGHLIGHTS

- Similarities between the prevalence of complaints in Minamata and Grassy Narrows
- Similarities in neurological findings were also found.
- Quantitative sensory measurements gave similar results for impairments.
- Younger Canadians were less severely affected than older ones.
- Results suggest that subjects from Grassy Narrows had methylmercury poisoning.

Quantitative somatosensory measurements

ABSTRACT

In 1970, fish caught in the English–Wabigoon River system in northwestern Ontario, Canada, were found to be contaminated with mercury coming from a chlor-alkali plant in the province. In the 1970s, patients exhibiting some of the symptoms of the Hunter–Russell syndrome (e.g. paresthesias, visual field constriction, ataxia, impaired hearing, and speech impairment) were reported by some researchers. However attempts to diagnose the patients as suffering from methylmercury poisoning proved to be controversial. In order to research the presence of methylmercury contamination, and show that the patients, through eating contaminated fish, were suffering from methylmercury poisoning, we studied the results of subjective complaints, neurological findings, and quantitative somatosensory measurements gathered in Grassy Narrows Indian Reservation, Ontario, in March, 2010. At that time, the population of the Grassy Narrows settlement was around 900. Ninety-one residents volunteered to be examined. From them, we selected 80 people who were older than 15 years old, and divided them into two groups. Canadian Younger (CY): 36 residents who were from 16 to 45 years old. Canadian Older (CO): 44 residents who were from 46 to 76 years old. We compared them to Japanese Exposed (JE): 88 methylmercury exposed residents from the Minamata district in Japan, and Japanese Control (JC): 164 control residents from non-polluted areas in Japan. Complaints and abnormal neurological findings were more prevalent and quantitative sensory measurements were worse in the two Canadian groups and the Japanese Exposed group than in the Japanese Control group. Complaints, neurological findings and quantitative sensory measurements were similar in Canadian Older and Japanese Exposed. The results for Canadian Younger fell between those of Canadian Older and Japanese Control. These findings indicate that the clinical signs and symptoms of the residents of Grassy Narrows are almost the same as those recorded for Minamata disease in Japan.

1. Introduction

Since the 1960s, a chlor-alkali plant had been releasing waste products contaminated with mercury into the waters of the English–Wabigoon River system in northwestern Ontario, Canada. In the first examples of fish, from the river system, that were contaminated with methylmercury (Bligh, 1970) levels of up to 16 μg/g were reported. Fimreite and Reynolds (1973) found highly contaminated fish with a maximum

methylmercury concentration of 27.8 μg/g in 1970. The contamination in fish there was almost equal to that measured in fish from Minamata Bay, Japan, where a barracuda was recorded as having 23 μg/g in May 1961 (Fujiki and Irukayama, 1979). The average mercury concentrations, measured in 1971, in walleye and northern pike from Ball Lake, English–Wabigoon River, were 1.99 μg/g and 5.05 μg/g respectively (Armstrong and Scott, 1979).

In 2003, results of similar measurements were 0.40 μg/g in walleye and 0.85 μg/g in northern pike (Kinghorn et al., 2007). The concentrations of mercury in fish are declining, but they are still higher than those found in fish in Minamata Bay, Japan, where the average concentration of mercury in fish has been from 0.17 to 0.42 μg/g during the period of 1998-2004. (Kindaichi and Matsuyama, 2005). Residents living in that area of Japan, still continue to be exposed to low levels of mercury from the eating of locally caught fish.

The two First Nations' communities living in Grassy Narrows and Whitedog Indian Reservations became victims of methylmercury poisoning through the consumption of locally caught fish. Patients with some of the Hunter–Russell syndrome symptoms have been reported in these reserves (Harada et al., 1976). Canadian researchers also examined the indigenous residents of the areas. Wheatley et al. (1979) reported that effects associated with methylmercury poisoning were observed, but they concluded that direct impacts on human health were difficult to prove.

Pathological studies of a cat from Whitedog, which exhibited acute neurological symptoms, revealed high mercury levels in the brain similar to those of Minamata disease in Japan (Takeuchi et al., 1977). Another cat from neighboring Grassy Narrows showed no symptoms, but on closer examination it was shown to have high mercury levels in the brain and latent defects caused by methylmercury poisoning (Takeuchi et al., 1977).

Since 2004, more than 60,000 people from the Minamata district have been diagnosed with abnormal neurological symptoms. In many cases, the abnormalities were being reported for the first time since the release of methylmercury contaminated wastewater was stopped in 1968 (Takaoka et al., 2009). In chronic methylmercury poisoning the somatosensory disturbance from cortical damage is specific and sensory disturbance is present either in all four limbs or throughout the body, sometimes with the exception of the face and head. To detect such abnormalities, quantitative sensory measurements are useful (Takaoka et al., 2008). So we carried out a health survey that included the examination of subjective complaints, neurological symptoms, and quantitative sensory measurements in Grassy Narrows, Ontario, Canada, in 2010 and tried to reassess the effect of methylmercury in this area.

2. Materials and methods

2.1. Subjects

The study was carried out in March 2010 in Grassy Narrows, Ontario, Canada. We contacted a Grassy Narrows support group and asked for their help. They informed the indigenous population of our coming survey to detect any health effects from methylmercury poisoning and asked for volunteers to take part in the study. The Chief of Grassy Narrows First Nation went on the local radio to ask for volunteers for our research. Posters, informing of our coming research project and our wish for volunteers, were displayed in the band office and a local store. Of the approximately 900 residents, 91 volunteered to be examined. We selected 80 residents, who were older than 15, for the study. Subjects were informed verbally and in writing about the examination method, how the data would be used and that their confidentiality would be protected. Each participant gave their written consent.

We divided them into two groups. (1) Group Canadian Younger (CY): consisted of 36 residents who were from 16 to 45 years old (M/F = 18/18, 34.4 ± 9.5 years old). (2) Group Canadian Older (CO): consisted of 44 residents who were from 46 to 76 years old (M/F = 19/25, 57.5 ± 8.1 years old).

We studied subjective symptoms, neurological findings and carried out four quantitative sensory measurements (including minimal tactile sensation, vibration, position sense, and two-point discrimination) among the 80 residents. In order to assess the state of health of the residents of Grassy Narrows, we compared them to a group of Japanese residents who had also been exposed to methylmercury as well as a group of Japanese control residents. These residents were the same people we had used as subjects in our previous study (Takaoka et al., 2008).

(3) Group Japanese Exposed (JE): was comprised of 88 randomly selected Japanese subjects. They were chosen from residents of the Minamata area who had been exposed to methylmercury and who had been included in our former study at the Minamata Kyoritsu Hospital and the Kyoritsu Neurology and Rehabilitation Clinic between November 2004 and April 2005. Their ages matched those of the corresponding Canadian group but the genders could not be matched exactly (M/F = 38/50, 59.0 ± 7.5). They answered a detailed questionnaire and were given a neurological examination including the same four quantitative sensory measurements as we performed in Canada. All of them were born before 1969. In our former study, we separated the subjects into those with and without neurological or neurologically related diseases, but we found that there was little difference between those two groups. So in this study, Group JE included subjects both with and without such related diseases.

(4) Group Japanese Control (JC): consisted of 164 residents who lived in other districts, e.g. around Fukuoka City, Kumamoto City, and Kagoshima City, aged between 40 and 79. In the control group, people who had lived around Minamata City or who suffered from a neurological disease or a neurologically related illness were excluded. The control subjects were examined between February and May 2006 (M/F = 67/97, 58.4 ± 11.6).

2.2. Epidemiological conditions and questionnaire on complications

The questionnaire, both in Canada and Japan, included questions to determine the subject's exposure to methylmercury and asked for information regarding place of residence, dietary habits, occupational history, medical complications and the health and medical histories of family members.

The questionnaire on complaints for the Canadian groups (CO and CY) consisted of 47 questions related to sensory impairment (7 items), somatic pain (4), visual impairment (3), hearing impairment (3), tasting and smelling problems (3), in-coordination of the extremities (4), other movement impairment (11), vertigo and dizziness (4), general complaints (2), and mental and intellectual problems (6).

The questionnaire on complaints for the Japanese groups (JE and JC) consisted of about 50 questions. We selected 35 relevant questions from the Japanese questionnaire and used them in the Canadian one. They were as follows: sensory impairment (4 items), somatic pain (3), visual impairment (3), hearing impairment (3), tasting and smelling problems (3), in-coordination of the extremities (5), other movement impairment (4), vertigo and dizziness (4), general complaints (2), and mental and intellectual problems (4).

In answer to questions on health complaints, subjects were asked to select one of 4 possible choices. 1) Yes, always, 2) Yes, sometimes, 3) Yes, in the past but not at present, and 4) No, never. The prevalence of each complaint was calculated for each group and then compared between the four groups. All subjects completed the questionnaire before their medical examination. Subjects who could not complete the questionnaire by themselves were asked the questions verbally. All questionnaires were reviewed prior to the examinations.

2.3. Standard neurological examination

A standard neurological examination was carried out on 32 of the 36 subjects in Group CY and on all 44 subjects in Group CO. Dysarthria, auditory disturbance, visual constriction, finger–nose test with the eyes open and closed, diadochokinesis, heel–shin test, gait disturbances, tandem gait test, Mann's test, balancing on one foot with eyes open and closed, and superficial sensory disturbance (touch and pain) were used and tested for. The examination methods and criteria were almost the same as the former study (Takaoka et al., 2008).

Dysarthria, auditory disturbance, visual constriction, postural hand tremors, gait disturbances and Romberg's sign were judged to be either present or absent. Dysarthria, auditory disturbance, and visual field constriction were judged by the examining physician without using special instruments. Tunnel vision was considered to be present when the confrontation test showed a lateral field of vision of 80° or less.

Limb and truncal ataxia were judged as being either absent, mildly abnormal or moderately to severely abnormal. The results of the finger–nose test and the heel–shin test were judged to be positive not only when there was constant dysmetria or decomposition but also when there was uncertain dysmetria, decomposition, or very slow movement involved. Dysdiadochokinesis was judged to be present from when there was a constant abnormality to when there was an uncertain abnormality or slow movement. Tandem gait disturbance was judged as present not only when the subject could not walk more than five steps but also when they could walk five steps but were unstable. In the balancing on one foot test, disequilibrium was judged as present when it was impossible to balance more than 3 s or when the subject was unstable, but could keep their balance for more than 3 s.

The examinations were carried out in Canada by one neurologist and four psychiatrists. The neurologist and two of the psychiatrists had previous experience in carrying out these tests from earlier examinations of Minamata disease patients. The other two psychiatrists had been briefed and trained to carry out the tests. In Japan, Group JE was examined by six physicians and one neurologist and Group JC was examined by forty-five physicians, several of whom were neurologists.

Because there was not enough data collected from Group JE for the finger–nose test with eyes closed, Mann's test, Romberg's sign or balancing on one foot with eyes closed test, we excluded that information from our calculations.

2.4. Quantitative sensory measurements

Four categories of tests were used in the quantitative measurement of the somatosensory system. All four categories were the same as in the former study (Takaoka et al., 2008).

2.4.1. Assessment of minimal tactile sense

The minimal tactile sense was measured by the Semmes–Weinstein monofilament test. Twenty kinds of filaments from 0.008 to 300 g were used. Subjects were tested with eyes closed after receiving clear instructions on which locations would be tested. Each filament was pushed until it bent about 90° for about a second. The threshold was the smallest size filament which a subject could feel as touch. The trial was performed starting from a smaller size filament and then gradually increasing the size.

Each filament was tested only once except when the subject was unsure. In that case the examiner, using the same filament, repeated the test an odd number of times and selected the dominant response. If a subject could not detect the maximum filament (300 g), we defined the threshold as 400 g for calculation. Testing was carried out on the lower lip, upper chest and ventral sides of both index fingers and big toes.

2.4.2. Vibration sense

Vibration sense was measured by using a 128 Hz tuning fork. The vibration test was carried out on the middle or upper sternum, the radial side of both wrists and the fibular side of both ankles. Subjects were told to indicate when they no longer could feel the vibrations. The examiner simultaneously struck a tuning fork and started a stopwatch, then placed the base of the fork against the area to be tested. The time interval until the subject reacted was recorded.

2.4.3. Position sense

The testing of position sense was carried out on subjects with their eyes closed. A ruler with a millimeter scale was used. Tests were carried out on the subject's index fingers and big toes. A ruler was placed vertically alongside the digit. With the digit held horizontally, the zero point was the position of the digit's nail on the ruler's scale. The examiner held the digit by its sides and moved it either up or down, holding the position for about 1 s. The subject was asked to indicate whether they felt the movement and if it was up or down. The upward or downward movement started from 5 mm from the zero point and was considered to be the minimum value. The movement was increased in 5 mm increments and the subject's threshold distance was recorded.

Each trial was carried out once for each distance except when the subject was uncertain. In that case the examiner would repeat the test again for an odd number of times and choose the dominant response. If the subject could not feel the maximum movement, the threshold was defined as the maximum distance plus 5 mm.

2.4.4. Two-point discrimination

The two-point discrimination test was carried out on subjects while their eyes were closed. A drafting divider, with the legs set at different distances, was pressed against the subject's skin at an angle of 30 to 45° to a depth of between 1 and 2 mm for about 1 s. The distances between the points used in the test were 1, 2, 3, 4, 5, 6, 8, 10, 12, 15, 20, 25, 30 and 36 mm. The threshold recorded was the shortest distance at which a subject answered correctly. This method was performed on the lower lip and the ventral side of each index finger. If the subject was unable to detect the maximum distance of 36 mm, the threshold was defined as 40 mm for calculation purposes.

In testing Groups CO and CY, the “Yes/No” method was used. However, when a subject felt that 1-point stimulation was actually 2-point stimulation, they were re-tested using the “2-alternative, forced-choice method”. In Groups JE and JC the “2-alternative, forced-choice method” was used exclusively.

2.5. Statistical methods

All the calculations were performed using MS Excel and SPSS. Chi square analysis was used in MS Excel when the prevalence was compared, and t-test was used in MS Excel when the average was compared. The correlations were calculated by SPSS.

When we calculated the minimal tactile sense, we converted the grams to the evaluator size using the equation: Evaluator size $=$ $\log([\text{gram}]) + 4$.

3. Results

3.1. The subjects' backgrounds

The age and sex of the subjects are shown in Table 1. The age and sex in Groups CO, JC and JE were not statistically different. The age of Group CY was less than the other groups.

From Table 2, we can see that 86% of Group CO and 83% of Group CY answered the question on how they obtained fish and over 60% of Groups CO and CY answered that they are catching fish by themselves. Also from Table 2, we can see that 41% of Group JE and 1% of Group JC

Table 1
Age and sex of each group.

	Age	n (M/F)
Group CO	57.5 ± 8.1	44 (19/25)
Group CY	34.4 ± 9.5	36 (18/18)
Group JE	59.0 ± 7.5	88 (38/50)
Group JC	58.4 ± 11.6	164 (67/97)

belonged to a fisher family. Ninety-three percent of Group JE and 25% of Group JC ate fish every day.

Table 3 shows the relevant medical history of Group CO and Group CY. The information was collected through interviews. On the question of hypertension, although some subjects had no recorded history of hypertension, high blood pressure was detected during the tests. If we detected a systolic pressure of 170 or more or and diastolic pressure of 110 or more in a subject, we recorded that hypertension was present. Some neurological or neurologically related diseases were found in 47 subjects (53%) of Group JE. No neurological or neurologically related diseases were found in Group JC.

3.2. Questionnaire on medical complaints

Medical complaints reported from each group are shown in Table 4, and the p-values by chi square among the four groups are shown in Table 5. In general, the prevalence in both "Yes, always" and "Yes, always" + "Yes, sometimes" in Groups JE, CO, and CY was statistically higher than Group JC. In general, the prevalence in Group JE and Group CO was similar. For most of the complaints Group CY showed a lower prevalence than Group CO.

The questionnaire consisted of questions related to specific and non-specific symptoms in the methylmercury polluted area. Specific symptoms included numbness, difficulty in speaking, fine-finger tasks, buttoning, losing slippers while walking, difficulty in differentiating tastes, detecting smells etc. Non-specific symptoms included headaches, forgetfulness, general fatigue, and so on. In specific symptoms, the prevalence of the answer "Yes, always" + "Yes, sometimes" was lower in Table 4. A tendency to a similar prevalence was observed both in specific and non-specific symptoms.

The correlation efficient among four groups was shown in Table 7. In "Yes, always" answers, the correlation between Groups JE and CO was highest, and was followed by the one between Groups CO and CY. In "Yes, always" + "Yes, sometimes" answers the correlation between Groups CO and CY was highest, and was followed by the one between Groups JE and CO and between Groups JE and CY.

Table 2
Fish sources and frequency of ingestion.

In Canada	Group CO	Group CY
Self-caught fish	28/44 (64%)	24/36 (67%)
Fish caught by relatives and friends, purchased etc.	30/44 (68%)	22/36 (61%)
A combination of both the above	38/44 (86%)	30/36 (83%)
In Japan	**Group JE**	**Group JC**
Fishermen	10/88 (11%)	0/164 (0%)
Fishermen's families	36/88 (41%)	1/164 (1%)
Sport fishing/recreational fishing	62/88 (70%)	17/161 (11%)[b]
Daily ingestion	81/87 (93%)[a]	40/157 (25%)[c]
Ingestion more than once a week	85/87 (98%)[a]	119/157 (76%)[c]

[a] Datum for 1 person was missing.
[b] Data for 3 persons were missing.
[c] Data for 7 persons were missing.

Table 3
Complications in Canadian subjects.

	Group CO	Group CY
Hypertension	15 (34%)	16 (44%)
Diabetes mellitus	8 (18%)	3 (8%)
Stroke	3 (7%)	1 (3%)
Lung diseases	0 (0%)	1 (3%)
Stomach diseases	6 (14%)	1 (3%)
Heart diseases	1 (2%)	0 (0%)
Orthopedic diseases	7 (16%)	4 (11%)
Psychiatric diseases	3 (7%)	1 (3%)

3.3. Neurological examination

The neurological findings for each group and p-values by chi-square among the four groups are shown in Table 6. The prevalence was generally highest in Group JE, and the prevalence of all the findings of Groups JE and CO was statistically higher than Group JC. All the findings of Group CY were less prevalent than Group CO, and seven of twelve findings of Group CO showed statistically higher prevalence than Group CY.

The most prevalent findings in Groups CO are tandem gait abnormality and somatosensory disturbances of pain and touch, followed by hearing impairment, truncal ataxia other than tandem gait abnormality, upper extremity ataxia (finger–nose test and diadochokinesis), and lower extremity ataxia (heel–shin test). The prevalence of visual constriction or dysarthria was lower. Although the orders of prevalence for the positive findings were different, the tendencies of the abnormalities were similar between Groups CO and JE.

Correlation among four groups was shown in Table 7. Correlations between Groups JE and CY, Groups CO and CY, and Groups JE and CO were higher than those between Group JC and other three groups, and p-values were lower.

3.4. Quantitative sensory measurements

3.4.1. Minimal tactile sensitivity using the Semmes–Weinstein monofilament test

Thirty-three subjects (75%) of Group CO and 24 subjects (67%) of Group CY were examined. One set of data for the lower lip in Group CO and one set of data for the left and right big toes in Group CY were absent. 84 of 88 subjects (95%) in Group JE (in which three sets of data were missing for the lower lip) and all 164 subjects of Group JC were examined and calculated.

Fig. 1 shows the results of the minimal tactile sensitivity using the Semmes–Weinstein monofilament test. The results were worst in Group CO, and there were distinct statistical differences between Groups CO, CY, and JC. Group JE was, in general, positioned between Groups CO and CY.

3.4.2. Vibration sense

Thirty-five subjects from Group CO and 25 subjects from Group CY were examined. Two subjects from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 33 subjects (75%) from Group CO and 24 subjects (67%) from Group CY were used in the calculation. Three sets of data for the right ankle and 4 sets of data for the left ankle were absent for Group CO. All 88 subjects of Group JE and all 164 subjects of Group JC (in which one set of data for the chest and one set of data for the left and right ankles were absent) were examined and calculated.

Fig. 2 shows that the vibration sense was worst in Group JE, followed by Group CO, Group CY and Group JC. Most of them had statistical differences between each other.

3.4.3. Position sense

Twenty-eight subjects from Group CO and 24 subjects from Group CY were examined. One subject from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 27 subjects (61%) from Group CO and 23 subjects (64%) from Group CY were used in the calculation. One set of data for the left and the right big toe, both upward and downward movements, was absent for Group CO. Eighty-seven subjects from Group JE (in which one set of data for both big toes in both directions was absent) and all 164 subjects of Group JC were examined and calculated.

Fig. 3 shows that the position sense was worst in Group JE, followed by Group CO, Group CY, and Group JC. Although there were some exceptions, most of the groups had statistical differences.

3.4.4. Two-point discrimination

Thirty-four subjects from Group CO and 25 subjects from Group CY were examined. Two subjects from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 32 subjects (73%) from Group CO and 24 subjects (67%) from Group CY were used in the calculation. 87 of 88 subjects (99%) from Group JE and all 164 subjects of Group JC (in which one set of data for the right index finger was absent) were examined and calculated.

Fig. 4 shows that the position sense was worst in Group JE or Group CO, followed by Group CY and finally Group JC. Most of them had statistical differences, except for the results for index fingers when comparing Group JE with Group CO.

4. Discussion

Our results show that subjective complaints were most prevalent in Group JE, followed by Groups CO, CY and JC. Similar and high prevalence of more specific complaints from methylmercury poisoning between Groups JE and CO suggest that these similarities are mainly related to methylmercury poisoning. The increase of non-specific complaints, which was found in Group JE, was also observed in Group CO.

The high prevalence of somatosensory disturbance and following ataxic movement in Groups JE and CO suggests that those two groups are similarly affected by methylmercury and Group CY is affected to a smaller extent by methylmercury. Harada et al. (1976) conducted health surveys on 89 indigenous inhabitants of Grassy Narrows and Whitedog and found sensory disturbance (47.6%), abnormality in visual field (18.0%), impaired hearing (44.9%), ataxia (9.0%), and dysarthria (5.6%). These findings together with the Hunter–Russell syndrome suggest methylmercury pollution in these communities.

Except for the high prevalence of tandem gait abnormality and hearing loss, the pattern of prevalence is almost the same as our study from the Minamata area in the 1970s (Fujino, 1994). Harada and his colleague visited Grassy Narrows in 2002 (Harada et al., 2005a) and Grassy Narrows and Whitedog in 2004 (Harada et al., 2005b). In 2002, glove and stocking type of sensory disturbance (54.4%), tunnel vision (10.5%), ataxia (12.3%) and impaired speech (12.3%) were observed in 57 subjects (Harada et al., 2005a). Combining the results of both studies, 2002 and 2004, glove and stocking type sensory disturbance was found in 65.1% of the cases, tunnel vision in 10.8%, ataxia in 25.1% and impaired speech in 6.9% of the 175 subjects (Harada et al., 2005b). As the criteria used for determining ataxia was not described in those papers, it is possible that the actual percentage could be greater than the papers suggested. We show the raw data for ataxic movement in this study.

Our present study differs from the former studies of 1975, 2002 and 2004, in that quantitative measurements of somatosensory disturbance were added to the study. The results of two-point discrimination sensitivity of the lower lip, vibration sense and position sense in big toes were also worse in Group JE, followed by Groups CO, CY and JC. Somatosensory acuity was most impaired in Group JE. Whereas minimal tactile sensitivity of the lower lip and left big toe were worst in Group CO, followed by Groups JE, CY and JC. The reason for these differences is, as yet, unascertained. As to two-point discrimination, the "Yes/No" method was used in testing Groups CO and CY, and the "2-alternative, forced-choice method" was used in testing of Groups JE and JC. But, in our experience, there were no great differences between results of these two methods.

Quantitative measurements showed that somatosensory disturbance, showing a similar pattern, was present in all tested body areas. These patterns are assumed to be the characteristics of somatosensory disturbance due to a uniformly injured central nervous system, especially the sensory cortex.

The similarity in the symptoms of abnormalities, neurological findings and quantitative measurements in Groups JE and CO were assumed to be produced by methylmercury poisoning. The intermediate abnormalities in Group CY suggest a milder and continuing effect of methylmercury poisoning in the younger generations of this area.

There are some limitations in this study. The first one is that the subjects in the study consisted of applicants who volunteered for the examination. The subjects in Groups JE, CO and CY ate a lot of fish, but the subjects in Group JC ate less fish. Also the lifestyle and occupations of the Japanese and the Canadian subjects are likely to be quite different. Also, the lifestyle and occupations were not the same in the two Japanese groups JE and JC.

Secondly we had no control area in Canada. Instead, we compared the Canadian results with the results from a control area in Japan, as well as from an exposed area in Japan.

Thirdly, there can be other factors involved which can affect the findings. In Groups CO and CY, some neurological diseases were found which confused the analysis of the test results. In order to overcome this limitation, we tried to compare a wide range of symptoms and complaints, neurological findings and quantitative measurements.

In the earlier study in Japan, we found that some complaints, symptoms, neurological findings, and quantitative measurements recorded could be affected by the presence of certain other neurological diseases. However, the similar patterns of symptoms, neurological findings, and quantitative sensory measurements cannot be explained without taking

into account the possibility of the presence of methylmercury poisoning (Takaoka et al., 2008).

After Harada's paper in 1976, the health effects of methylmercury on indigenous Canadians (First Nations) were reported by Canadian researchers. Barbeau et al. (1976) reported that he discovered symptoms like Minamata disease patients in Quebec, but he soon modified and toned down his conclusions. Shephard (1979) admitted the higher exposure in Canadian Indians and insisted that there was no agreement on the clinical diagnosis of mercury poisoning. But no conclusive human health-related data of Canadian Indians were presented by them. Wheatley et al. (1979) reported that they failed to prove abnormalities attributable to methylmercury. But his study in 1979 was based on clinical and pathological test results taken from only one male Cree Indian.

In north-western Quebec, McKeown-Eyssen and Ruedy (1983) studied individuals from the Cree First Nation and reported incoordination (15.4% in males/6.5% in females in Mistassini, 44.2% in males/26.5% in females in Great Whale), abnormal perception of sensations (5.7% in males/4.3% in females in Mistassini, 9.3% in males/2.1% in females in Great Whale). The results for subjects who had visual field scores of over 55° were 16.0% in males and 19.4% in females in Mistassini, and 0.7% in males and 15.5% in females in Great Whale. Although the patterns of abnormalities are very different from our results, the presence of these abnormalities could suggest milder methylmercury poisoning. The Canadian researchers did not, however, come to this conclusion. It would appear that they did not follow up and observe the individuals for a longer period of time, which is unfortunate. In our new Minamata disease cases, observed from November 2004 to April 2005, about half of them were considered to have had their first abnormalities after 1968, the year when the Chisso Company ceased to release methylmercury contaminated industrial wastewater (Takaoka et al., 2009).

Spitzer et al. (1988) found no abnormalities in north-western Quebec when they compared people from the Cree First Nation with a control group. In this study, the exposed group (SDD: The Self Designated Disease Group) and other three control groups were compared. Visual constriction was observed in 4.9% of SDD and in 0.0–1.7% of other groups. Peripheral sensory disturbance (written as "peripheral neuropathy" in the paper) was observed in 9.9% of SDD and in 1.5–3.1% of other groups. There was a higher tendency in the prevalence in SDD, but there was no statistical difference between SDD and other groups.

In examining the Cree people, McKeown-Eyssen et al. (1990) emphasized inter-observer variation. It is more important, however, to do the same examination in the control area and to set criteria for judging the results of the examination, rather than to repeat an examination in the same group. Even though there were some variations and differences between the results obtained by the screener and the results of the neurological examination by the neurologist, e.g. prevalence of tremor (screener 40.2%, neurologist 29.9%) and incoordination (screener 22.8%, neurologist 15.4%) in men in Mistassini, they were still high. They also had differences in criteria when identifying neurological abnormalities, but it should be possible to set standard criteria for the assessment of the neurological findings similar to our methods.

Changeability of neurological functions is quite common in cases of Minamata disease. In Minamata disease the range of four limb

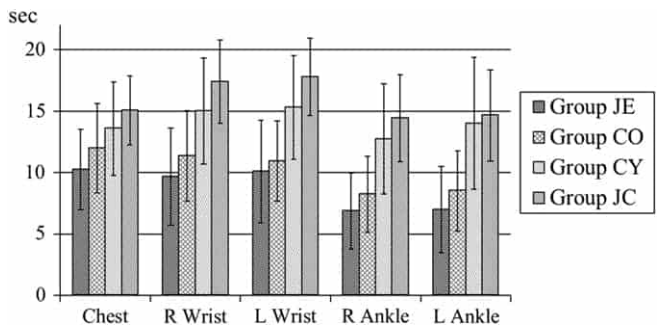

Fig. 2. Threshold for vibration sense — group comparisons. JC, JE: $p < 0.01$ (all locations), JC, CO: $p < 0.01$ (all locations), JC, CY: $p < 0.01$ (bilateral wrist), $p < 0.05$ (chest and R. ankle), n.s. (L. ankle), JE, CO: $p < 0.01$ (chest), n.s. (L wrist), $p < 0.05$ (other locations), JE, CY: $p < 0.01$ (all locations), and CO, CY: n.s. (chest), $p < 0.01$ (all other locations).

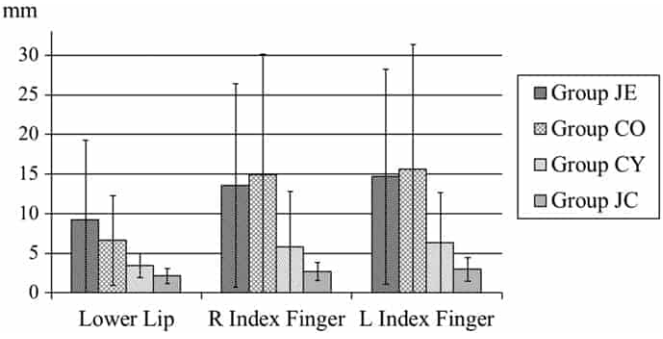

Fig. 4. Threshold for two-point discrimination — group comparisons. JC, JE: $p < 0.01$ (all locations), JC, CO: $p < 0.01$ (all locations), JC, CY: $p < 0.05$ (R index finger), $p < 0.01$ (other locations), JE, CO: $p < 0.05$ (lower lip), n.s. (other locations), JE, CY: $p < 0.01$ (all locations), and CO, CY: $p < 0.01$ (all locations).

somatosensory disturbance is changeable. Uchino and Araki (1984) reported on 100 cases of Minamata disease. In 77 of the 100 cases the examination for superficial sensory disturbance was carried out from 2 to 5 times, and 63 of the 77 cases (82%) were recorded as "unstable type" in which the area of the body showing somatosensory disturbance changed. The most important factor in showing the effect of environmental pollution on the inhabitants of an area is the ability to gather data and information from both the people exposed to the pollution and from a control group which has not been exposed.

There are some other Canadian studies about the exposure to methylmercury (Wheatley and Paradis, 1996; Wheatley et al., 1997; Wheatley and Paradis, 1998), but there are few that take into account epidemiological human health data. Wheatley (1996) stressed that the people of the First Nations understanding of mercury contamination is influenced by their holistic concepts of health and environment. But there was too little physical data available to corroborate this concept. Without the presence of human physical data, we cannot evaluate psychological, social and spiritual values of health.

5. Conclusions

The data collected from methylmercury-exposed indigenous residents of Grassy Narrows suggest that they were poisoned by methylmercury. The health abnormalities also appear to exist in a milder form in the younger generations from Grassy Narrows.

Information on funding sources

The study was conducted partly with funding from Grants-in-Aid for Scientific Research of Japan Society for the Promotion of Science (JSPS) (No. 20330118). The title of the funding is "Studies on the reappraisal of the real situation of Minamata disease damages and their social impact in the past half-century."

Conflict of interest

There is no conflict of interest in this study.

Acknowledgment

We, the authors, would like to express our thanks to the late Masazumi Harada of the Open Research Center for Minamata Studies, Kumamoto Gakuen University, for his planning and involvement in carrying out this research, by dedicating this paper to his memory.

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Shigeru Takaoka. I live in the City of Minamata in the Prefecture of Kumamoto.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

AFFIDAVIT OF TADASHI FUJINO

I, TADASHI FUJINO, of the City of Kumamoto, in the Prefecture of Kumamoto, Japan MAKE OATH AND SAY AS FOLLOWS:

1. I am a medical doctor specializing in psychiatry and neurology at Kumamoto Hospital, in the City of Kumamoto, in the Prefecture of Kumamoto. I have considerable clinical experience examining patients exposed to mercury in Minamata, Japan. At various times, over several decades, I also undertook, with a team of researchers lead by the late Dr.

Masazumi Harada, many clinical examinations of men, women, and children suspected of being exposed to mercury in Grassy Narrows, Ontario, Canada. I have written extensively about my clinical investigations in both countries in a number of medical and scientific peer-reviewed journals. A copy of my curriculum vitae is attached to Exhibit "A" of the affidavit of Shigeru Takaoka for this proceeding.

2. In December 2015 I, along with my colleagues Drs. Shigeru Takaoka and Akitomo Shimoji were asked by counsel for Grassy Narrows First Nation to answer certain questions on medical-psychological/psychiatric issues pertaining to mercury exposure at Grassy Narrows. The questions and our answers to them appear as part of our May 2016 expert report attached as Exhibit "A" to the affidavit of Shigeru Takaoka.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "A" to my Affidavit.

藤野糺の宣誓供述書

私、日本国熊本県熊本市在住の藤野糺は下記のことを宣誓供述致します。

1. 私は熊本県熊本市にある熊本病院で精神科と神経内科を専門としている医師です。私は日本の水俣において水銀汚染された患者の住民健診の経験が豊富であります。数十年に渡り、何度も原田正純医師率いる調査チームと共にカナダ・オンタリオ州グラッシー・ナローズで水銀汚染されたと疑われる男性女性児童の住民検診を多く手がけました。両国において臨床研究について広範囲にわたり論文を執筆し、それらは論文審査のある多くの医学科学専門誌で発表されました。私の履歴書はこの訴訟のために、高岡滋氏の宣誓供述書の証拠品 A に添付されています。
2. 2015 年 12 月、私と同僚の高岡滋医師、下地明友医師はグラッシー・ナローズ・ファースト・ネーションの弁護士からグラッシー・ナローズにおける水銀汚染に係る医学的、心理学的、そして精神的影響に関するいくつかの質問に回答するように依頼されました。質問と回答は高岡滋氏の供述宣誓書に証拠品 A として添付されている 2016 年 5 月専門家報告書の一部として記載されています。
3. 私の専門家全責任承認フォーム 1 部が証拠品 A として私の供述宣誓書に添付されています。

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Akitomo Shimoji. I live in the City of Kumamoto in the Prefecture of Kumamoto.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

AFFIDAVIT OF MINAKO MIYATA

I, MINAKO MIYATA, of the City of Markham, in the Province of Ontario, MAKE OATH AND SAY AS FOLLOWS:

1. I am a contractor with Multilingual Community Interpreter Services ("MCIS") in Toronto, Ontario where I provide Japanese-English interpretation and translation services in a wide variety of contexts.

2. I am fully qualified to translate Japanese and English. My professional qualifications, work experience, education, and membership affiliations are included in my curriculum vitae, attached as Exhibit “A” to my Affidavit.

3. In July 2016, I was asked by MCIS to verify that the Japanese and English versions of the material that appears in Exhibit “B” to my Affidavit are identical. I am very familiar with this material due to my having previously translated it, except for what is identified in paragraph 5, below, from English to Japanese or Japanese to English, as the circumstances required, in the period December 2015 to April 2016.

4. I have carefully reviewed the Japanese and English versions of the documents produced to me by MCIS identified below that appear in Exhibit “B” to my Affidavit, including:

   (a) Affidavit of Shigeru Takaoka;

   (b) Expert Report of Drs. Shigeru Takaoka, Tadashi Fujino, and Akitomo Shimoji entitled “Response to Questions on Medical-Psychological/Psychiatric Issues Pertaining to Mercury Exposure at Grassy Narrows”;

   (c) Acknowledgement of Expert’s Duty by Shigeru Takaoka;

   (d) Affidavit of Tadashi Fujino;

   (e) Acknowledgement of Expert’s Duty by Tadashi Fujino;

   (f) Affidavit of Akitomo Shimoji; and

   (g) Acknowledgement of Expert’s Duty by Akitomo Shimoji.

5. The Japanese and English versions of the above documents are in all material respects identical to each other except that the Japanese versions of the documents: (1) have been

signed by Shigeru Takaoka, Tadashi Fujino, or Akitomo Shimoji, as appropriate; (2) contain various dates in May 2016 (May 27 or May 28, 2016) in the jurat; and (3) contain the signature of John Donald Davis, and the jurat in the Japanese documents states that he is a commissioner for taking oaths.

6. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "C" to my Affidavit.

SWORN BEFORE ME in the City of Toronto, in the Province of Ontario, this ___ day of July, 2016.

AFFIDAVIT OF SHIGERU TAKAOKA

I, SHIGERU TAKAOKA, of the City of Minamata, in the Prefecture of Kumamoto, Japan MAKE OATH AND SAY AS FOLLOWS:

1. I am a medical doctor and director of the Kyoritsu Neurology and Rehabilitation Clinic, in the City of Minamata, in the Prefecture of Kumamoto, where I specialize in the areas of neurological, rehabilitative, and general internal medicine. I have participated in clinical examinations of patients suspected of having been exposed to mercury in

Minamata, Japan and Grassy Narrows, Ontario, Canada, the latter experience as part of a team of researchers lead by the late Dr. Masazumi Harada. In addition to my clinical work, I am also the co-author of several articles on the subject of exposure to mercury that have been published in a number of peer-reviewed medical and scientific journals. A copy of my curriculum vitae is attached to Exhibit "A", below.

2. In December 2015 I, along with my colleagues Drs. Tadashi Fujino and Akitomo Shimoji were asked by counsel for Grassy Narrows First Nation to answer certain questions on medical-psychological/psychiatric issues pertaining to mercury exposure at Grassy Narrows. The questions and our answers to them appear as part of our May 2016 expert report attached as Exhibit "A" to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "B" to my Affidavit.

SWORN BEFORE ME in the City of Minamata, in the Prefecture of Kumamoto, Japan, this ___ day of _____, 2016.

Introduction: Expertise and Qualifications

We are three doctors who practice in Kumamoto Prefecture on the island of Kyushu in Japan. The following is a brief summary of our experience and expertise:

Dr. Shigeru Takaoka: I am a medical doctor and director of the Kyoritsu Neurology and Rehabilitation Clinic, Minamata, Kumamoto, Japan where I specialize in a number of areas, including neurological, rehabilitative, and general internal medicine. I have participated in clinical examinations of patients suspected of having been exposed to mercury in Minamata, Japan and Grassy Narrows, Ontario, Canada, the latter experience as part of a team of researchers lead by the late Dr. Masazumi Harada. In addition to my clinical work, I am also the co-author of several articles on the subject of exposure to mercury that have been published in a number of peer-reviewed medical and scientific journals.

Dr. Tadashi Fujino: I am a medical doctor specializing in psychiatry and neurology at Kumamoto Hospital. I have considerable clinical experience examining patients exposed to mercury in Minamata, Japan. At various times, over several decades, I also undertook, with a team of researchers lead by the late Dr. Masazumi Harada, many clinical examinations of men, women, and children suspected of being exposed to mercury in Grassy Narrows, Ontario, Canada. I have written extensively about my clinical investigations in both countries in numerous medical and scientific peer-reviewed journals.

Dr. Akitomo Shimoji: I am a medical doctor, neuro-psychiatrist, and professor at Kumamoto Gakuen University. Along with a team of researchers lead by the late Dr. Masazumi Harada, I participated in clinical examinations of patients exposed or suspected of having been exposed to mercury in Grassy Narrows, Ontario, Canada. Based on my clinical experience in Japan, I also have authored or co-authored several articles that have been published in peer-reviewed medical and scientific journals on the subject of exposure to mercury.

Our curriculum vitae appear in Appendix B of our Expert Report.

Instructions and Nature of Professional Opinion Sought

We have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare an expert report that responds to four questions that are reproduced below. We are solely responsible for the answers to the questions contained in this report. Page references contained in the questions set out below are from the Applicants' Application Record in *Grassy Narrows First Nation, et al v. Minister of Natural Resources and Forestry (Ontario), et al.*

List of Questions Asked

Questions for Dr. Shigeru Takaoka et al.		
English	**Japanese**	**Reference Page**
Question 1: Based on the clinical medical examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on the statements, which appear below respecting pages 001251 to 001252 of the January 2014 request by Grassy Narrows (GN) to the Government of Ontario, and whether they are accurate in their summary of the findings of Dr. Harada's team based on the two Harada referenced reports of 2005 and 2011 that appear at page 001284 of the January 2014 request?		
Excerpt from: Bump-up Request for an Individual Environmental Assessment (IEA) submitted to the Ontario Ministry of the Environment regarding the Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022 - Final Plan Inspection Approved by the Ministry of Natural Resources, December 23, 2013 - EBR Registry No. 010-9240 Submitted by: Grassy Narrows First Nation and Earthroots January 22, 2014 5. Mercury Impacts Human Health in Grassy Narrows SUMMARY 35 Years of study by renowned mercury expert Dr. Harada and his team have confirmed that people in Grassy Narrows are suffering from Minamata Disease as a result of methyl mercury ingested by eating local fish. EVIDENCE Doctor Harada's teams of researchers have studied mercury health impacts in Grassy Narrows for over 35 years starting in 1975. "[I]t is an undoubtable fact that Minamata Disease occurred in [Grassy Narrows and White Dog], based on our long-term investigation result." (Harada et al., 2011) Grassy Narrows people "were poisoned by eating fish contaminated with mercury." (Harada et al., 2011) Findings by Harada et al., 2011 • 59% of the 160 people tested in GN and White Dog were affected by mercury. • 34% were diagnosed with Minamata Disease (MD)		1251-1252

using current Japanese diagnostic criteria (41% in GN --> 30 cases) • 25% were diagnosed with suspected Minamata Disease (SMD) • 44% of people aged 21-40 had MD or SMD. All these people were born after the mercury dumping was curtailed in 1971. "[T]he possibility of congenital Minamata Disease occurrence is very high in these two communities. We examined 7 cases of cerebral palsy and 7 cases of mental deficiency.... Further epidemiological research on stillbirths and miscarriages needs to be done." (Harada et al., 2005) All of Dr. Harada's patients who indicated mercury levels higher than the safetyguideline of 50 ppm in 1975 were deceased by 2004. (Harada et al., 2005)		
References Cited Section of Previous Excerpted Document: Harada, Masazumi, Masanori Hanada, Masami Tajiri, Yukari Inoue, Nobuyuki Hotta, Tadashi Fujino, Shigeru Takaoka, and Keishi Ueda. 2011. "Mercury Poisoning in First Nations Groups in Ontario, Canada 35 Years of Minamata Disease in Canada." Journal of Minamata Studies 3: 3–30. Harada, Masazumi, Masanori Hanada, Takashi Miyakita, Tadashi Fujino, Kazuhito Tsuruta, Akira Fukuhara, Tadashi Orui, Shigeharu Nakachi, Chihito Araki, and Masami Tajiri. 2005. "Long-Term Study on the Effects of Mercury Contamination on Two Indigenous Communities in Canada (1975-2004)." Research on Environmental Disruption 34 (4).		1284
Question 2: Based on the clinical medical examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on the statements, which appear below respecting pages 001445, 001479 to 001483 of the September 2014 supplementary GN submissions to the Government of Ontario, and whether they are accurate in their summary of the findings of Dr. Harada's team referred to in those pages?		

The following 5 Excerpts are from: Literature Review regarding the Impact of Mercury on Human Health Summary of a text produced by Drs. Laurie Chan and Donna Mergler for the Mercury Disability Board presented by Donna Mergler PhD, Professor Emerita, University of Quebec at Montreal: Dr. Harada's studies • Dr. Harada did pioneering work in Japan, demonstrating neurologic damage of Minamata Disease • In a recent report, he stated: "During the early stages of the MD crisis in Minamata, patients, who were diagnosed with MD, seemed to be typical and severe cases of the Hunter-Russell syndrome, including sensory disturbance, concentric constriction of the visual field, ataxia, speech impairment and impaired hearing. However, through more study, it became clear that such severe cases were rather exceptional and many more mild cases were progressing to chronic Minamata Disease. I observed that the symptoms of Minamata Disease became more chronic and atypical in the 1970s. Also I have been proving that sensory disturbances, specifically stronger loss of sensation in the extremities, were seen among patients of methylmercury poisoning at a very high rate, through clinical examinations on family members of patients with sever(sic) and typical symptoms or mothers of congenital Minamata Disease patients"		1479
Dr. Harada's studies • In the '70s, he showed that persons in Grassy Narrows and White Dog manifested similar signs and symptoms to MD and there appeared to be a dose-relation with mercury exposure • In 2002 and 2004, he and his team went back. In total they examined 156 people from Grassy Narrows and White Dog. • Age ranged from 1-90 years • No information was provided on how persons were recruited		1480
Dr. Harada's studies • Diagnostic criteria: • MD: more than one symptom of: sensory disturbances, ataxia, disturbed ocular movement, imbalance, concentric constr[i]ction of the visual field and speech impairment. • In cases where examinees were showing only sensory disturbances, we acknowledged MD as long as there was no other disease causing the symptom. • If an examinee had another disease and still showed symptoms of MD that were not explained by that other disease, we defined the case as MD with complications.		1481

Dr. Harada's studies • Findings: • 60 cases of MD (34.2% of total examinees, excluding people 10 years old and younger); • 54 cases (30.8%) of MD with complications; • 25 cases (14.2%) of possible MD for a total of 139 cases (79.4%). • They conclude : • It is very high rate of neurological symptoms for a sample of a population, even though examinees came because of other health issues. It is as high as contaminated areas in Minamata. We cannot help but recognize the effects of methylmercury from the symptoms we have seen.		1482
Our conclusions [of Drs. Chan and Mergler] • Dr Harada and his group did not evaluate the prevalence of MD in this population, but reported on the percentage of MD signs and symptoms within the group that they examined. • We consider that Dr. Harada's follow-up clinical evaluation should be seen as a preliminary study showing the need for a comprehensive epidemiologic study that would include all of the known outcomes of mercury exposure and could take into account co-morbidity from other diseases, such as diabetes and /or alcohol and test for possible interactions. Such a study should also take into account the presence of other contaminants. For this study it would be most useful to have all of the results of hair and blood sampling by Health Canada, Dr. Chan and Dr. Harada, as well as the results of the neurological examinations that were done by Dr. Harada.		1483
Question 3: Based on the clinical psychological/psychiatric examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on whether you agree with the statements of Donnan, 1986, regarding the psychological health impacts of mercury/methylmercury, which statements appear below respecting pages 001492 to 001493 of the November 2014 supplementary GN submissions to the Government of Ontario? In your professional opinion, has exposure to mercury had psychological/psychiatric impacts on the people of Grassy Narrows and, if so, what have been those impacts?		

Excerpts from: Grassy Narrows and Earthroots Fourth Supplementary Submission to Devon Wills, Ministry of the Environment on 2012-2022 Whiskey Jack Forest Management Plan IEA Request, dated November 14, 2014 2. PSYCHOLOGICAL HEALTH IMPACTS OF MERCURY "High blood mercury levels contribute to anxiety..." (Donnan, MOE 1986, p.28) "...mental health effects such as anxiety due to mercury contamination in the Wabigoon- English River System have been borne almost entirely by the Native people of the Grassy Narrows and Whitedog Bands." (Donnan, MOE 1986, p.28) The fear and anxiety from knowing they were contaminated was debilitating to many. The threat of mercury poisoning clearly affected the mental health of these people...." (Donnan, MOE 1986, p.31) "[A] reduction in fish mercury levels could help to reduce anxiety and mental trauma experienced by these people." (Donnan, MOE 1986, p.44)		1492-1493
Question 4: Do you continue to adopt the findings and conclusions contained in the article by Shigeru Takaoka, et al, entitled "Signs and symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" reported in Science of the Total Environment 468-469 (2014) 950-957? If not, what has caused you to change your opinion since publication of the article?		

Answers to Questions

Question No. 1

They are accurate.

Question No. 2

They are accurate.

Question No. 3

In our professional opinion, yes, there were negative psychiatric effects.

Question No. 4

We continue to support them.

HIGHLIGHTS

- Similarities between the prevalence of complaints in Minamata and Grassy Narrows
- Similarities in neurological findings were also found.
- Quantitative sensory measurements gave similar results for impairments.
- Younger Canadians were less severely affected than older ones.
- Results suggest that subjects from Grassy Narrows had methylmercury poisoning.

ABSTRACT

In 1970, fish caught in the English–Wabigoon River system in northwestern Ontario, Canada, were found to be contaminated with mercury coming from a chlor-alkali plant in the province. In the 1970s, patients exhibiting some of the symptoms of the Hunter–Russell syndrome (e.g. paresthesias, visual field constriction, ataxia, impaired hearing, and speech impairment) were reported by some researchers. However attempts to diagnose the patients as suffering from methylmercury poisoning proved to be controversial. In order to research the presence of methylmercury contamination, and show that the patients, through eating contaminated fish, were suffering from methylmercury poisoning, we studied the results of subjective complaints, neurological findings, and quantitative somatosensory measurements gathered in Grassy Narrows Indian Reservation, Ontario, in March, 2010. At that time, the population of the Grassy Narrows settlement was around 900. Ninety-one residents volunteered to be examined. From them, we selected 80 people who were older than 15 years old, and divided them into two groups. Canadian Younger (CY): 36 residents who were from 16 to 45 years old. Canadian Older (CO): 44 residents who were from 46 to 76 years old. We compared them to Japanese Exposed (JE): 88 methylmercury exposed residents from the Minamata district in Japan, and Japanese Control (JC): 164 control residents from non-polluted areas in Japan. Complaints and abnormal neurological findings were more prevalent and quantitative sensory measurements were worse in the two Canadian groups and the Japanese Exposed group than in the Japanese Control group. Complaints, neurological findings and quantitative sensory measurements were similar in Canadian Older and Japanese Exposed. The results for Canadian Younger fell between those of Canadian Older and Japanese Control. These findings indicate that the clinical signs and symptoms of the residents of Grassy Narrows are almost the same as those recorded for Minamata disease in Japan.

1. Introduction

Since the 1960s, a chlor-alkali plant had been releasing waste products contaminated with mercury into the waters of the English–Wabigoon River system in northwestern Ontario, Canada. In the first examples of fish, from the river system, that were contaminated with methylmercury (Bligh, 1970) levels of up to 16 μg/g were reported. Fimreite and Reynolds (1973) found highly contaminated fish with a maximum

2606
123

methylmercury concentration of 27.8 μg/g in 1970. The contamination in fish there was almost equal to that measured in fish from Minamata Bay, Japan, where a barracuda was recorded as having 23 μg/g in May 1961 (Fujiki and Irukayama, 1979). The average mercury concentrations, measured in 1971, in walleye and northern pike from Ball Lake, English–Wabigoon River, were 1.99 μg/g and 5.05 μg/g respectively (Armstrong and Scott, 1979).

In 2003, results of similar measurements were 0.40 μg/g in walleye and 0.85 μg/g in northern pike (Kinghorn et al., 2007). The concentrations of mercury in fish are declining, but they are still higher than those found in fish in Minamata Bay, Japan, where the average concentration of mercury in fish has been from 0.17 to 0.42 μg/g during the period of 1998-2004. (Kindaichi and Matsuyama, 2005). Residents living in that area of Japan, still continue to be exposed to low levels of mercury from the eating of locally caught fish.

The two First Nations' communities living in Grassy Narrows and Whitedog Indian Reservations became victims of methylmercury poisoning through the consumption of locally caught fish. Patients with some of the Hunter–Russell syndrome symptoms have been reported in these reserves (Harada et al., 1976). Canadian researchers also examined the indigenous residents of the areas. Wheatley et al. (1979) reported that effects associated with methylmercury poisoning were observed, but they concluded that direct impacts on human health were difficult to prove.

Pathological studies of a cat from Whitedog, which exhibited acute neurological symptoms, revealed high mercury levels in the brain similar to those of Minamata disease in Japan (Takeuchi et al., 1977). Another cat from neighboring Grassy Narrows showed no symptoms, but on closer examination it was shown to have high mercury levels in the brain and latent defects caused by methylmercury poisoning (Takeuchi et al., 1977).

Since 2004, more than 60,000 people from the Minamata district have been diagnosed with abnormal neurological symptoms. In many cases, the abnormalities were being reported for the first time since the release of methylmercury contaminated wastewater was stopped in 1968 (Takaoka et al., 2009). In chronic methylmercury poisoning the somatosensory disturbance from cortical damage is specific and sensory disturbance is present either in all four limbs or throughout the body, sometimes with the exception of the face and head. To detect such abnormalities, quantitative sensory measurements are useful (Takaoka et al., 2008). So we carried out a health survey that included the examination of subjective complaints, neurological symptoms, and quantitative sensory measurements in Grassy Narrows, Ontario, Canada, in 2010 and tried to reassess the effect of methylmercury in this area.

2. Materials and methods

2.1. Subjects

The study was carried out in March 2010 in Grassy Narrows, Ontario, Canada. We contacted a Grassy Narrows support group and asked for their help. They informed the indigenous population of our coming survey to detect any health effects from methylmercury poisoning and asked for volunteers to take part in the study. The Chief of Grassy Narrows First Nation went on the local radio to ask for volunteers for our research. Posters, informing of our coming research project and our wish for volunteers, were displayed in the band office and a local store. Of the approximately 900 residents, 91 volunteered to be examined. We selected 80 residents, who were older than 15, for the study. Subjects were informed verbally and in writing about the examination method, how the data would be used and that their confidentiality would be protected. Each participant gave their written consent.

We divided them into two groups. (1) Group Canadian Younger (CY): consisted of 36 residents who were from 16 to 45 years old (M/F = 18/18, 34.4 ± 9.5 years old). (2) Group Canadian Older (CO): consisted of 44 residents who were from 46 to 76 years old (M/F = 19/25, 57.5 ± 8.1 years old).

We studied subjective symptoms, neurological findings and carried out four quantitative sensory measurements (including minimal tactile sensation, vibration, position sense, and two-point discrimination) among the 80 residents. In order to assess the state of health of the residents of Grassy Narrows, we compared them to a group of Japanese residents who had also been exposed to methylmercury as well as a group of Japanese control residents. These residents were the same people we had used as subjects in our previous study (Takaoka et al., 2008).

(3) Group Japanese Exposed (JE): was comprised of 88 randomly selected Japanese subjects. They were chosen from residents of the Minamata area who had been exposed to methylmercury and who had been included in our former study at the Minamata Kyoritsu Hospital and the Kyoritsu Neurology and Rehabilitation Clinic between November 2004 and April 2005. Their ages matched those of the corresponding Canadian group but the genders could not be matched exactly (M/F = 38/50, 59.0 ± 7.5). They answered a detailed questionnaire and were given a neurological examination including the same four quantitative sensory measurements as we performed in Canada. All of them were born before 1969. In our former study, we separated the subjects into those with and without neurological or neurologically related diseases, but we found that there was little difference between those two groups. So in this study, Group JE included subjects both with and without such related diseases.

(4) Group Japanese Control (JC): consisted of 164 residents who lived in other districts, e.g. around Fukuoka City, Kumamoto City, and Kagoshima City, aged between 40 and 79. In the control group, people who had lived around Minamata City or who suffered from a neurological disease or a neurologically related illness were excluded. The control subjects were examined between February and May 2006 (M/F = 67/97, 58.4 ± 11.6).

2.2. Epidemiological conditions and questionnaire on complications

The questionnaire, both in Canada and Japan, included questions to determine the subject's exposure to methylmercury and asked for information regarding place of residence, dietary habits, occupational history, medical complications and the health and medical histories of family members.

The questionnaire on complaints for the Canadian groups (CO and CY) consisted of 47 questions related to sensory impairment (7 items), somatic pain (4), visual impairment (3), hearing impairment (3), tasting and smelling problems (3), in-coordination of the extremities (4), other movement impairment (11), vertigo and dizziness (4), general complaints (2), and mental and intellectual problems (6).

The questionnaire on complaints for the Japanese groups (JE and JC) consisted of about 50 questions. We selected 35 relevant questions from the Japanese questionnaire and used them in the Canadian one. They were as follows: sensory impairment (4 items), somatic pain (3), visual impairment (3), hearing impairment (3), tasting and smelling problems (3), in-coordination of the extremities (5), other movement impairment (4), vertigo and dizziness (4), general complaints (2), and mental and intellectual problems (4).

In answer to questions on health complaints, subjects were asked to select one of 4 possible choices. 1) Yes, always, 2) Yes, sometimes, 3) Yes, in the past but not at present, and 4) No, never. The prevalence of each complaint was calculated for each group and then compared between the four groups. All subjects completed the questionnaire before their medical examination. Subjects who could not complete the questionnaire by themselves were asked the questions verbally. All questionnaires were reviewed prior to the examinations.

2607
124

2.3. Standard neurological examination

A standard neurological examination was carried out on 32 of the 36 subjects in Group CY and on all 44 subjects in Group CO. Dysarthria, auditory disturbance, visual constriction, finger–nose test with the eyes open and closed, diadochokinesis, heel–shin test, gait disturbances, tandem gait test, Mann's test, balancing on one foot with eyes open and closed, and superficial sensory disturbance (touch and pain) were used and tested for. The examination methods and criteria were almost the same as the former study (Takaoka et al., 2008).

Dysarthria, auditory disturbance, visual constriction, postural hand tremors, gait disturbances and Romberg's sign were judged to be either present or absent. Dysarthria, auditory disturbance, and visual field constriction were judged by the examining physician without using special instruments. Tunnel vision was considered to be present when the confrontation test showed a lateral field of vision of 80° or less.

Limb and truncal ataxia were judged as being either absent, mildly abnormal or moderately to severely abnormal. The results of the finger–nose test and the heel–shin test were judged to be positive not only when there was constant dysmetria or decomposition but also when there was uncertain dysmetria, decomposition, or very slow movement involved. Dysdiadochokinesis was judged to be present from when there was a constant abnormality to when there was an uncertain abnormality or slow movement. Tandem gait disturbance was judged as present not only when the subject could not walk more than five steps but also when they could walk five steps but were unstable. In the balancing on one foot test, disequilibrium was judged as present when it was impossible to balance more than 3 s or when the subject was unstable, but could keep their balance for more than 3 s.

The examinations were carried out in Canada by one neurologist and four psychiatrists. The neurologist and two of the psychiatrists had previous experience in carrying out these tests from earlier examinations of Minamata disease patients. The other two psychiatrists had been briefed and trained to carry out the tests. In Japan, Group JE was examined by six physicians and one neurologist and Group JC was examined by forty-five physicians, several of whom were neurologists.

Because there was not enough data collected from Group JE for the finger–nose test with eyes closed, Mann's test, Romberg's sign or balancing on one foot with eyes closed test, we excluded that information from our calculations.

2.4. Quantitative sensory measurements

Four categories of tests were used in the quantitative measurement of the somatosensory system. All four categories were the same as in the former study (Takaoka et al., 2008).

2.4.1. Assessment of minimal tactile sense

The minimal tactile sense was measured by the Semmes–Weinstein monofilament test. Twenty kinds of filaments from 0.008 to 300 g were used. Subjects were tested with eyes closed after receiving clear instructions on which locations would be tested. Each filament was pushed until it bent about 90° for about a second. The threshold was the smallest size filament which a subject could feel as touch. The trial was performed starting from a smaller size filament and then gradually increasing the size.

Each filament was tested only once except when the subject was unsure. In that case the examiner, using the same filament, repeated the test an odd number of times and selected the dominant response. If a subject could not detect the maximum filament (300 g), we defined the threshold as 400 g for calculation. Testing was carried out on the lower lip, upper chest and ventral sides of both index fingers and big toes.

2.4.2. Vibration sense

Vibration sense was measured by using a 128 Hz tuning fork. The vibration test was carried out on the middle or upper sternum, the radial side of both wrists and the fibular side of both ankles. Subjects were told to indicate when they no longer could feel the vibrations. The examiner simultaneously struck a tuning fork and started a stopwatch, then placed the base of the fork against the area to be tested. The time interval until the subject reacted was recorded.

2.4.3. Position sense

The testing of position sense was carried out on subjects with their eyes closed. A ruler with a millimeter scale was used. Tests were carried out on the subject's index fingers and big toes. A ruler was placed vertically alongside the digit. With the digit held horizontally, the zero point was the position of the digit's nail on the ruler's scale. The examiner held the digit by its sides and moved it either up or down, holding the position for about 1 s. The subject was asked to indicate whether they felt the movement and if it was up or down. The upward or downward movement started from 5 mm from the zero point and was considered to be the minimum value. The movement was increased in 5 mm increments and the subject's threshold distance was recorded.

Each trial was carried out once for each distance except when the subject was uncertain. In that case the examiner would repeat the test again for an odd number of times and choose the dominant response. If the subject could not feel the maximum movement, the threshold was defined as the maximum distance plus 5 mm.

2.4.4. Two-point discrimination

The two-point discrimination test was carried out on subjects while their eyes were closed. A drafting divider, with the legs set at different distances, was pressed against the subject's skin at an angle of 30 to 45° to a depth of between 1 and 2 mm for about 1 s. The distances between the points used in the test were 1, 2, 3, 4, 5, 6, 8, 10, 12, 15, 20, 25, 30 and 36 mm. The threshold recorded was the shortest distance at which a subject answered correctly. This method was performed on the lower lip and the ventral side of each index finger. If the subject was unable to detect the maximum distance of 36 mm, the threshold was defined as 40 mm for calculation purposes.

In testing Groups CO and CY, the "Yes/No" method was used, However, when a subject felt that 1-point stimulation was actually 2-point stimulation, they were re-tested using the "2-alternative, forced-choice method". In Groups JE and JC the "2-alternative, forced-choice method" was used exclusively.

2.5. Statistical methods

All the calculations were performed using MS Excel and SPSS. Chi square analysis was used in MS Excel when the prevalence was compared, and t-test was used in MS Excel when the average was compared. The correlations were calculated by SPSS.

When we calculated the minimal tactile sense, we converted the grams to the evaluator size using the equation: Evaluator size = log([gram]) + 4.

3. Results

3.1. The subjects' backgrounds

The age and sex of the subjects are shown in Table 1. The age and sex in Groups CO, JC and JE were not statistically different. The age of Group CY was less than the other groups.

From Table 2, we can see that 86% of Group CO and 83% of Group CY answered the question on how they obtained fish and over 60% of Groups CO and CY answered that they are catching fish by themselves. Also from Table 2, we can see that 41% of Group JE and 1% of Group JC

2608
125

Table 1
Age and sex of each group.

	Age	n (M/F)
Group CO	57.5 ± 8.1	44 (19/25)
Group CY	34.4 ± 9.5	36 (18/18)
Group JE	59.0 ± 7.5	88 (38/50)
Group JC	58.4 ± 11.6	164 (67/97)

belonged to a fisher family. Ninety-three percent of Group JE and 25% of Group JC ate fish every day.

Table 3 shows the relevant medical history of Group CO and Group CY. The information was collected through interviews. On the question of hypertension, although some subjects had no recorded history of hypertension, high blood pressure was detected during the tests. If we detected a systolic pressure of 170 or more or and diastolic pressure of 110 or more in a subject, we recorded that hypertension was present. Some neurological or neurologically related diseases were found in 47 subjects (53%) of Group JE. No neurological or neurologically related diseases were found in Group JC.

3.2. Questionnaire on medical complaints

Medical complaints reported from each group are shown in Table 4, and the p-values by chi square among the four groups are shown in Table 5. In general, the prevalence in both "Yes, always" and "Yes, always" + "Yes, sometimes" in Groups JE, CO, and CY was statistically higher than Group JC. In general, the prevalence in Group JE and Group CO was similar. For most of the complaints Group CY showed a lower prevalence than Group CO.

The questionnaire consisted of questions related to specific and non-specific symptoms in the methylmercury polluted area. Specific symptoms included numbness, difficulty in speaking, fine-finger tasks, buttoning, losing slippers while walking, difficulty in differentiating tastes, detecting smells etc. Non-specific symptoms included headaches, forgetfulness, general fatigue, and so on. In specific symptoms, the prevalence of the answer "Yes, always" + "Yes, sometimes" was lower in Table 4. A tendency to a similar prevalence was observed both in specific and non-specific symptoms.

The correlation efficient among four groups was shown in Table 7. In "Yes, always" answers, the correlation between Groups JE and CO was highest, and was followed by the one between Groups CO and CY. In "Yes, always" + "Yes, sometimes" answers the correlation between Groups CO and CY was highest, and was followed by the one between Groups JE and CO and between Groups JE and CY.

Table 2
Fish sources and frequency of ingestion.

In Canada	Group CO	Group CY
Self-caught fish	28/44 (64%)	24/36 (67%)
Fish caught by relatives and friends, purchased etc.	30/44 (68%)	22/36 (61%)
A combination of both the above	38/44 (86%)	30/36 (83%)
In Japan	**Group JE**	**Group JC**
Fishermen	10/88 (11%)	0/164 (0%)
Fishermen's families	36/88 (41%)	1/164 (1%)
Sport fishing/recreational fishing	62/88 (70%)	17/161 (11%)[b]
Daily ingestion	81/87 (93%)[a]	40/157 (25%)[c]
Ingestion more than once a week	85/87 (98%)[a]	119/157 (76%)[c]

[a] Datum for 1 person was missing.
[b] Data for 3 persons were missing.
[c] Data for 7 persons were missing.

Table 3
Complications in Canadian subjects.

	Group CO	Group CY
Hypertension	15 (34%)	16 (44%)
Diabetes mellitus	8 (18%)	3 (8%)
Stroke	3 (7%)	1 (3%)
Lung diseases	0 (0%)	1 (3%)
Stomach diseases	6 (14%)	1 (3%)
Heart diseases	1 (2%)	0 (0%)
Orthopedic diseases	7 (16%)	4 (11%)
Psychiatric diseases	3 (7%)	1 (3%)

3.3. Neurological examination

The neurological findings for each group and p-values by chi-square among the four groups are shown in Table 6. The prevalence was generally highest in Group JE, and the prevalence of all the findings of Groups JE and CO was statistically higher than Group JC. All the findings of Group CY were less prevalent than Group CO, and seven of twelve findings of Group CO showed statistically higher prevalence than Group CY.

The most prevalent findings in Groups CO are tandem gait abnormality and somatosensory disturbances of pain and touch, followed by hearing impairment, truncal ataxia other than tandem gait abnormality, upper extremity ataxia (finger–nose test and diadochokinesis), and lower extremity ataxia (heel–shin test). The prevalence of visual constriction or dysarthria was lower. Although the orders of prevalence for the positive findings were different, the tendencies of the abnormalities were similar between Groups CO and JE.

Correlation among four groups was shown in Table 7. Correlations between Groups JE and CY, Groups CO and CY, and Groups JE and CO were higher than those between Group JC and other three groups, and p-values were lower.

3.4. Quantitative sensory measurements

3.4.1. Minimal tactile sensitivity using the Semmes–Weinstein monofilament test

Thirty-three subjects (75%) of Group CO and 24 subjects (67%) of Group CY were examined. One set of data for the lower lip in Group CO and one set of data for the left and right big toes in Group CY were absent. 84 of 88 subjects (95%) in Group JE (in which three sets of data were missing for the lower lip) and all 164 subjects of Group JC were examined and calculated.

Fig. 1 shows the results of the minimal tactile sensitivity using the Semmes–Weinstein monofilament test. The results were worst in Group CO, and there were distinct statistical differences between Groups CO, CY, and JC. Group JE was, in general, positioned between Groups CO and CY.

3.4.2. Vibration sense

Thirty-five subjects from Group CO and 25 subjects from Group CY were examined. Two subjects from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 33 subjects (75%) from Group CO and 24 subjects (67%) from Group CY were used in the calculation. Three sets of data for the right ankle and 4 sets of data for the left ankle were absent for Group CO. All 88 subjects of Group JE and all 164 subjects of Group JC (in which one set of data for the chest and one set of data for the left and right ankles were absent) were examined and calculated.

Fig. 2 shows that the vibration sense was worst in Group JE, followed by Group CO, Group CY and Group JC. Most of them had statistical differences between each other.

3.4.3. Position sense

Twenty-eight subjects from Group CO and 24 subjects from Group CY were examined. One subject from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 27 subjects (61%) from Group CO and 23 subjects (64%) from Group CY were used in the calculation. One set of data for the left and the right big toe, both upward and downward movements, was absent for Group CO. Eighty-seven subjects from Group JE (in which one set of data for both big toes in both directions was absent) and all 164 subjects of Group JC were examined and calculated.

Fig. 3 shows that the position sense was worst in Group JE, followed by Group CO, Group CY, and Group JC. Although there were some exceptions, most of the groups had statistical differences.

3.4.4. Two-point discrimination

Thirty-four subjects from Group CO and 25 subjects from Group CY were examined. Two subjects from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 32 subjects (73%) from Group CO and 24 subjects (67%) from Group CY were used in the calculation. 87 of 88 subjects (99%) from Group JE and all 164 subjects of Group JC (in which one set of data for the right index finger was absent) were examined and calculated.

Fig. 4 shows that the position sense was worst in Group JE or Group CO, followed by Group CY and finally Group JC. Most of them had statistical differences, except for the results for index fingers when comparing Group JE with Group CO.

Table 5

4. Discussion

Our results show that subjective complaints were most prevalent in Group JE, followed by Groups CO, CY and JC. Similar and high prevalence of more specific complaints from methylmercury poisoning between Groups JE and CO suggest that these similarities are mainly related to methylmercury poisoning. The increase of non-specific complaints, which was found in Group JE, was also observed in Group CO.

The high prevalence of somatosensory disturbance and following ataxic movement in Groups JE and CO suggests that those two groups are similarly affected by methylmercury and Group CY is affected to a smaller extent by methylmercury. Harada et al. (1976) conducted health surveys on 89 indigenous inhabitants of Grassy Narrows and Whitedog and found sensory disturbance (47.6%), abnormality in visual field (18.0%), impaired hearing (44.9%), ataxia (9.0%), and dysarthria (5.6%). These findings together with the Hunter–Russell syndrome suggest methylmercury pollution in these communities.

Except for the high prevalence of tandem gait abnormality and hearing loss, the pattern of prevalence is almost the same as our study from the Minamata area in the 1970s (Fujino, 1994). Harada and his colleague visited Grassy Narrows in 2002 (Harada et al., 2005a) and Grassy Narrows and Whitedog in 2004 (Harada et al., 2005b). In 2002, glove and stocking type of sensory disturbance (54.4%), tunnel vision (10.5%), ataxia (12.3%) and impaired speech (12.3%) were observed in 57 subjects (Harada et al., 2005a). Combining the results of both studies, 2002 and 2004, glove and stocking type sensory disturbance was found in 65.1% of the cases, tunnel vision in 10.8%, ataxia in 25.1% and impaired speech in 6.9% of the 175 subjects (Harada et al., 2005b). As the criteria used for determining ataxia was not described in those papers, it is possible that the actual percentage could be greater than the papers suggested. We show the raw data for ataxic movement in this study.

Our present study differs from the former studies of 1975, 2002 and 2004, in that quantitative measurements of somatosensory disturbance were added to the study. The results of two-point discrimination sensitivity of the lower lip, vibration sense and position sense in big toes were also worse in Group JE, followed by Groups CO, CY and JC. Somatosensory acuity was most impaired in Group JE. Whereas minimal tactile sensitivity of the lower lip and left big toe were worst in Group CO, followed by Groups JE, CY and JC. The reason for these differences is, as yet, unascertained. As to two-point discrimination, the "Yes/No" method was used in testing Groups CO and CY, and the "2-alternative, forced-choice method" was used in testing of Groups JE and JC. But, in our experience, there were no great differences between results of these two methods.

Quantitative measurements showed that somatosensory disturbance, showing a similar pattern, was present in all tested body areas. These patterns are assumed to be the characteristics of somatosensory disturbance due to a uniformly injured central nervous system, especially the sensory cortex.

The similarity in the symptoms of abnormalities, neurological findings and quantitative measurements in Groups JE and CO were assumed to be produced by methylmercury poisoning. The intermediate abnormalities in Group CY suggest a milder and continuing effect of methylmercury poisoning in the younger generations of this area.

There are some limitations in this study. The first one is that the subjects in the study consisted of applicants who volunteered for the examination. The subjects in Groups JE, CO and CY ate a lot of fish, but the subjects in Group JC ate less fish. Also the lifestyle and occupations of the Japanese and the Canadian subjects are likely to be quite different. Also, the lifestyle and occupations were not the same in the two Japanese groups JE and JC.

Secondly we had no control area in Canada. Instead, we compared the Canadian results with the results from a control area in Japan, as well as from an exposed area in Japan.

Thirdly, there can be other factors involved which can affect the findings. In Groups CO and CY, some neurological diseases were found which confused the analysis of the test results. In order to overcome this limitation, we tried to compare a wide range of symptoms and complaints, neurological findings and quantitative measurements.

In the earlier study in Japan, we found that some complaints, symptoms, neurological findings, and quantitative measurements recorded could be affected by the presence of certain other neurological diseases. However, the similar patterns of symptoms, neurological findings, and quantitative sensory measurements cannot be explained without taking

into account the possibility of the presence of methylmercury poisoning (Takaoka et al., 2008).

After Harada's paper in 1976, the health effects of methylmercury on indigenous Canadians (First Nations) were reported by Canadian researchers. Barbeau et al. (1976) reported that he discovered symptoms like Minamata disease patients in Quebec, but he soon modified and toned down his conclusions. Shephard (1979) admitted the higher exposure in Canadian Indians and insisted that there was no agreement on the clinical diagnosis of mercury poisoning. But no conclusive human health-related data of Canadian Indians were presented by them. Wheatley et al. (1979) reported that they failed to prove abnormalities attributable to methylmercury. But his study in 1979 was based on clinical and pathological test results taken from only one male Cree Indian.

In north-western Quebec, McKeown-Eyssen and Ruedy (1983) studied individuals from the Cree First Nation and reported incoordination (15.4% in males/6.5% in females in Mistassini, 44.2% in males/26.5% in females in Great Whale), abnormal perception of sensations (5.7% in males/4.3% in females in Mistassini, 9.3% in males/2.1% in females in Great Whale). The results for subjects who had visual field scores of over 55° were 16.0% in males and 19.4% in females in Mistassini, and 0.7% in males and 15.5% in females in Great Whale. Although the patterns of abnormalities are very different from our results, the presence of these abnormalities could suggest milder methylmercury poisoning. The Canadian researchers did not, however, come to this conclusion. It would appear that they did not follow up and observe the individuals for a longer period of time, which is unfortunate. In our new Minamata disease cases, observed from November 2004 to April 2005, about half of them were considered to have had their first abnormalities after 1968, the year when the Chisso Company ceased to release methylmercury contaminated industrial wastewater (Takaoka et al., 2009).

Spitzer et al. (1988) found no abnormalities in north-western Quebec when they compared people from the Cree First Nation with a control group. In this study, the exposed group (SDD: The Self Designated Disease Group) and other three control groups were compared. Visual constriction was observed in 4.9% of SDD and in 0.0–1.7% of other groups. Peripheral sensory disturbance (written as "peripheral neuropathy" in the paper) was observed in 9.9% of SDD and in 1.5–3.1% of other groups. There was a higher tendency in the prevalence in SDD, but there was no statistical difference between SDD and other groups.

In examining the Cree people, McKeown-Eyssen et al. (1990) emphasized inter-observer variation. It is more important, however, to do the same examination in the control area and to set criteria for judging the results of the examination, rather than to repeat an examination in the same group. Even though there were some variations and differences between the results obtained by the screener and the results of the neurological examination by the neurologist, e.g. prevalence of tremor (screener 40.2%, neurologist 29.9%) and incoordination (screener 22.8%, neurologist 15.4%) in men in Mistassini, they were still high. They also had differences in criteria when identifying neurological abnormalities, but it should be possible to set standard criteria for the assessment of the neurological findings similar to our methods.

Changeability of neurological functions is quite common in cases of Minamata disease. In Minamata disease the range of four limb

somatosensory disturbance is changeable. Uchino and Araki (1984) reported on 100 cases of Minamata disease. In 77 of the 100 cases the examination for superficial sensory disturbance was carried out from 2 to 5 times, and 63 of the 77 cases (82%) were recorded as "unstable type" in which the area of the body showing somatosensory disturbance changed. The most important factor in showing the effect of environmental pollution on the inhabitants of an area is the ability to gather data and information from both the people exposed to the pollution and from a control group which has not been exposed.

There are some other Canadian studies about the exposure to methylmercury (Wheatley and Paradis, 1996; Wheatley et al., 1997; Wheatley and Paradis, 1998), but there are few that take into account epidemiological human health data. Wheatley (1996) stressed that the people of the First Nations understanding of mercury contamination is influenced by their holistic concepts of health and environment. But there was too little physical data available to corroborate this concept. Without the presence of human physical data, we cannot evaluate psychological, social and spiritual values of health.

5. Conclusions

The data collected from methylmercury-exposed indigenous residents of Grassy Narrows suggest that they were poisoned by methylmercury. The health abnormalities also appear to exist in a milder form in the younger generations from Grassy Narrows.

Information on funding sources

The study was conducted partly with funding from Grants-in-Aid for Scientific Research of Japan Society for the Promotion of Science (JSPS) (No. 20330118). The title of the funding is "Studies on the reappraisal of the real situation of Minamata disease damages and their social impact in the past half-century."

Conflict of interest

There is no conflict of interest in this study.

Acknowledgment

We, the authors, would like to express our thanks to the late Masazumi Harada of the Open Research Center for Minamata Studies, Kumamoto Gakuen University, for his planning and involvement in carrying out this research, by dedicating this paper to his memory.

Akitomo Shimoji

Education

1973 Graduated Faculty of Medicine, Kumamoto University

1973 Started work at Department of Neuropsychiatry, Faculty of Life Sciences, Kumamoto University

1975 Tomiai Prefectural Hospital Kumamoto (currently called Kokoro Medical Center)

1977 Research Associate, Poisoning Research Center, Neurotoxin Sector, Kumamoto University

1981 Research Associate, Department of Psychiatry, Kumamoto University

1987 Chief Psychiatrist, Okinawa Miyako Hospital

1989 Lecturer, Department of Neuropsychiatry, Kumamoto University

1997 Associate Professor, Department of Neuropsychiatry (Clinical Psychology), Kumamoto University

2004 Associate Professor, Department of Psychiatry and Neuropathology, Graduate School of Medicine and Faculty of Medicine of Kumamoto University (Chief Psychiatrist, Department of Neuropsychiatry)

2005 Professor, Graduate School and Faculty of Social Welfare of Kumamoto Gakuen University (Welfare Environmental Studies)

Clinical research experience in in Canada

August 2014 Participated in clinical research in Grassy Narrows and Whitedog

付録 A: 2014 年に書かれた記事 – カナダ・オンタリオ州北西部に位置する北米先住民族コミュニティーにおけるメチル水銀汚染の兆候と症状 11
付録 B: 著者の履歴書 20

前書き：専門分野と資格

私たちは日本の九州に位置する熊本県の３人の医師です。下記の内容は私たちの経験と専門分野の簡潔な要約です。

高岡滋医師：私は医師で日本国熊本県水俣市にある神経内科リハビリテーション協立クリニックの院長です。私の専門は幅広く、神経内科とリハビリテーションそして一般内科です。私は日本の水俣市とカナダ国オンタリオ州グラッシーナローズにて水銀汚染されたと疑われる患者の住民健診に参加しました。グラッシー・ナローズにおいては原田正純医師率いる調査チームに参加しました。臨床経験に加え、私は水銀汚染に関する論文をいくつか共同で執筆し、それらは論文審査のある医学科学専門誌で発表されました。

藤野糺医師：私は熊本病院で精神科と神経内科を専門としている医師です。私は日本の水俣において水銀汚染された患者の住民健診の経験が豊富であります。数十年に渡り、何度も原田正純医師率いる調査チームと共にカナダ国オンタリオ州グラッシー・ナローズで水銀汚染されたと疑われる男性女性児童の住民検診を多く手がけました。両国において臨床研究について広範囲にわたり論文を執筆し、それらは論文審査のある多くの医学科学専門誌で発表されました。

下地明友医師：私は神経精神科医であり、熊本大学の教授でもあります。故原田正純医師率いる調査チームと共にカナダ国オンタリオ州グラッシー・ナローズにおいて水銀汚染された又は水銀汚染が疑われた患者の臨床評価に参加しました。日本における臨床経験に基づき、私は水銀汚染に関する論文を執筆・共同執筆し、それらは論文審査のある医学科学専門誌で発表されました。

私たちの履歴書は専門家報告書の付録Ｂに記載されています。

専門的意見を依頼された経緯と背景

私たちはグラッシー・ナローズ・ファースト・ネーションを代理であるカナダ環境法協会のジョゼフ・Ｆ・カストリリ氏とリチャード・Ｄ・リンドグレン氏より下記の４つの質問に回答として専門家報告書の作成を依頼されました。質問の中に出てくる参照ページは原告の申請記録「グラッシー・ナローズ・ファースト・ネーション及びその他、対オンタリオ州天然資源省森林局及びその他」から引用しています。

Questions for Dr. Shigeru Takaoka et al.	高岡滋医師とそのチームにへの質問	
English	日本語	関連ページ
Question 1: Based on the clinical medical examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on the statements, which appear below respecting pages 001251 to 001252 of the January 2014 request by Grassy Narrows (GN) to the Government of Ontario, and whether they are accurate in their summary of the findings of Dr. Harada's team based on the two Harada referenced reports of 2005 and 2011 that appear at page 001284 of the January 2014 request?	**質問１：原田医師とそのチームがグラッシー・ナローズで長年に渡って行った臨床医療調査をもとに、下記のステートメントにコメントしてください。2014 年 1 月にオンタリオ州政府へグラッシー・ナローズから提出されたリクエストの 001251 ページから 001252 ページに関連しています。それらは 2014 年 1 月のリクエストの 001284 ページに記載されている、原田医師が書いた 2005 年と 2011 年の報告書に基づいて原田医師のチームが出した調査結果はその要旨において正確でしょうか。**	
Excerpt from: Bump-up Request for an Individual Environmental Assessment (IEA) submitted to the Ontario Ministry of the Environment regarding the Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022 - Final Plan Inspection Approved by the Ministry of Natural Resources, December 23, 2013 - EBR Registry No. 010-9240 Submitted by: Grassy Narrows First Nation and Earthroots January 22, 2014 5. Mercury Impacts Human Health in Grassy Narrows SUMMARY 35 Years of study by renowned mercury expert Dr. Harada and his team have confirmed that people in Grassy Narrows are suffering from Minamata Disease as a result of methyl mercury ingested by eating local fish. EVIDENCE Doctor Harada's teams of researchers have studied mercury health impacts in Grassy Narrows for over 35 years starting in 1975. "[I]t is an undoubtable fact that Minamata Disease occurred in [Grassy Narrows and White Dog], based on our long-term investigation result." (Harada et al., 2011) Grassy Narrows people "were poisoned by eating fish contaminated with mercury." (Harada et al., 2011) Findings by Harada et al., 2011	次より抜粋：2012 年 4 月 1 日から 2022 年 3 月 31 日までの 10 年間に及ぶウィスキー・ジャック・フォレストの森林管理計画に関してオンタリオ州環境省に提出された個別環境調査(IEA)への再リクエスト- オンタリオ州天然資源省より 2013 年 12 月 23 日に承認された最終計画監査。EBR Registry No. 010-9240 2014 年 1 月 22 日にグラッシー・ナローズ ファーストネーションとアースルートにより提出。 ５．グラッシー・ナローズにおいての水銀の人間の健康への影響 要旨 水銀の専門家として有名な原田医師とそのチームによって行われた 35 年に及ぶ調査により、グラッシー・ナローズ住民は地元で採れた魚を食することによって摂取したメチル水銀が原因で水俣病に苦しんでいることが確認された。 証拠 原田医師の研究者チームは 1975 年以来 35 年に渡りグラッシー・ナローズにおいて水銀の健康に対する影響を調査した。 「長期間に及ぶ調査の結果、（グラッシー・ナローズとホワイト・ドッグでは）水俣病が発生したことは疑う余地のない事実である。」（原田医師とそのチーム、2011 年） グラッシー・ナローズの人々は「水銀に汚染された魚を摂取することにより汚染された。」（原田医師とそのチーム、2011 年） 原田医師とそのチームによって発見された事実	1251-1252

• 59% of the 160 people tested in GN and White Dog were affected by mercury. • 34% were diagnosed with Minamata Disease (MD) using current Japanese diagnostic criteria (41% in GN --> 30 cases) • 25% were diagnosed with suspected Minamata Disease (SMD) • 44% of people aged 21-40 had MD or SMD. All these people were born after the mercury dumping was curtailed in 1971. "[T]he possibility of congenital Minamata Disease occurrence is very high in these two communities. We examined 7 cases of cerebral palsy and 7 cases of mental deficiency.... Further epidemiological research on stillbirths and miscarriages needs to be done." (Harada et al., 2005) All of Dr. Harada's patients who indicated mercury levels higher than the safetyguideline of 50 ppm in 1975 were deceased by 2004. (Harada et al., 2005)	(2011 年) • グラッシー・ナローズとホワイト・ドッグで検査を受けた 160 名の 59%が水銀に汚染されていた。 • 現在の日本の診断基準に基づき、34%が水俣病（MD）と診断された。（グラッシー・ナローズでは 41%、30 件以上） • 25%は水俣病の疑いあり（SMD）と診断された。 • 21 歳か 40 歳の 44%が MD 又は SMD と診断された。全員が 1971 年に水銀放出が削減された以降に生まれている。 「これらの２つのコミュニティーにおいて先天的水俣病発生率は極めて高い。脳性まひ 7 症例と知的障害 7 症例を調査した。死産と流産に関しては、より詳しい疫学的調査を実施する必要がある。」（原田医師とそのチーム、2005 年） 原田医師の患者全員で、1975 年には水銀レベルが 50 ppm の安全指針よりも高かったが、2004 年までには下がった。（原田医師とそのチーム、2005 年）

Question 2: Based on the clinical medical examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on the statements, which appear below respecting pages 001445, 001479 to 001483 of the September 2014 supplementary GN submissions to the Government of Ontario, and whether they are accurate in their summary of the findings of Dr. Harada's team referred to in those pages?	**質問２：原田医師とそのチームがグラッシー・ナローズで長年に渡って行った臨床医療調査をもとに、下記のステートメントにコメントしてください。2014 年 9 月にグラッシー・ナローズがオンタリオ州政府に提出した補足提出の 001445 ページ、 001479 ページと 001483 ページに関連しています。それらは原田医師のチームがこれらのページおいて言及している調査結果はその要旨において正確でしょうか？**	

The following 5 Excerpts are from: Literature Review regarding the Impact of Mercury on Human Health Summary of a text produced by Drs. Laurie Chan and Donna Mergler for the Mercury Disability Board presented by Donna Mergler PhD, Professor Emerita, University of Quebec at Montreal: Dr. Harada's studies • Dr. Harada did pioneering work in Japan, demonstrating neurologic damage of Minamata Disease • In a recent report, he stated: "During the early stages of the MD crisis in Minamata, patients, who were diagnosed with MD, seemed to be typical and severe cases of the Hunter-Russell syndrome, including sensory disturbance, concentric constriction of the visual field, ataxia, speech impairment and impaired hearing. However, through more study, it became clear that such severe cases were rather exceptional and many more mild cases were progressing to chronic Minamata Disease. I observed that the symptoms of Minamata Disease became more chronic and atypical in the 1970s. Also I have been proving that sensory disturbances, specifically stronger loss of sensation in the extremities, were seen among patients of methylmercury poisoning at a very high rate, through clinical examinations on family members of patients with sever(sic) and typical symptoms or mothers of congenital Minamata Disease patients"	下記の 5 つは次からの抜粋です。人間の健康に及ぼす水銀の影響に関する文献の考察 ローリー・チャン博士とドナ・マーグラー博士により水銀障害委員会のために作成された文章の要旨 モントリオール、ケベック大学名誉教授ドナ・マーグラー博士によって公開されました。 原田医師の調査 • 原田医師は日本で草分け的な調査を行い、水俣病の神経系の障害を証明した。 • 最近の報告書にて、彼は「水俣市における水俣病騒動の初期において、水俣病患者は知覚障害、視野の求心性収縮、運動失調、発語障害と聴覚障害などの、ハンター＝ラッセル症候群患者に典型的でかつ重度な症状が見受けられた。しかしながら、より多くの調査を通じて、そのような重度な症例はどちらかというと例外的で、多くの軽症例が慢性的水俣病へ移行していくことが明確になった。水俣病の症状は 1970 年代に、より慢性で変則的なものとなったことが認められ。また私は、先天性水俣病患者の家族または母親の臨床検査を通じて、知覚障害、厳密に言えば、四肢におけるより強度な知覚喪失がメタル水銀中毒患者に非常に高い率で診られることを証明した。」と述べている。	1479
Dr. Harada's studies • In the '70s, he showed that persons in Grassy Narrows and White Dog manifested similar signs and symptoms to MD and there appeared to be a dose-relation with mercury exposure • In 2002 and 2004, he and his team went back. In total they examined 156 people from Grassy Narrows and White Dog. • Age ranged from 1-90 years • No information was provided on how persons were recruited	原田医師の調査 • 70 年代に、彼はグラッシー・ナローズとホワイト・ドッグの住人に水俣病に似た兆候と症状が現われ、水銀の摂取量と関係があることを明らかにした。 • 2002 年と 2004 年に彼と彼のチームは現地へ戻り、グラッシー・ナローズとホワイト・ドッグで合計 156 名を調査した。 ・年齢は 1 歳から 90 歳 ・調査対象の選出法については一切公表されていない	1480

Dr. Harada's studies • Diagnostic criteria: • MD: more than one symptom of: sensory disturbances, ataxia, disturbed ocular movement, imbalance, concentric constr[i]ction of the visual field and speech impairment. • In cases where examinees were showing only sensory disturbances, we acknowledged MD as long as there was no other disease causing the symptom. • If an examinee had another disease and still showed symptoms of MD that were not explained by that other disease, we defined the case as MD with complications.	原田医師の調査 ・診断基準 • 水俣病：知覚障害、運動失調、眼球運動障害、平衡失調、視野の求心性収縮、発語障害の症状のいずれかが一つ以上認められる。 • 調査対象で知覚障害のみが認められた場合、その症状を引き起こす他の疾患が認められない場合は水俣病と認識した。 • 調査対象が他の疾患を持ちながら水俣病症状を表し、その症状が他の疾患によるものではない場合、そのケースは合併症を伴う水俣病とした。	1481
Dr. Harada's studies • Findings: • 60 cases of MD (34.2% of total examinees, excluding people 10 years old and younger); • 54 cases (30.8%) of MD with complications; • 25 cases (14.2%) of possible MD for a total of 139 cases (79.4%). • They conclude : • It is very high rate of neurological symptoms for a sample of a population, even though examinees came because of other health issues. It is as high as contaminated areas in Minamata. We cannot help but recognize the effects of methylmercury from the symptoms we have seen.	原田医師の調査 ・調査結果 ・60 の症例が水俣病（調査対象全員の 34.2%、10 歳以下を除く） ・54 の症例（30.8%）が合併症を伴う水俣病 ・合計 139 の症例（79.4%）のうち 25 の症例（14.2%）が水俣病の疑いがある ・結論 ・調査対象が他の健康問題で来たにもかかわらず、住民の実例としては神経症状はかなり高い率で見られた。それは水俣の汚染地域と同じくらい高かった。我々が見た症状からするとメチル水銀の影響と認識せざるを得ない。	1482
Our conclusions [of Drs. Chan and Megler] • Dr Harada and his group did not evaluate the prevalence of MD in this population, but reported on the percentage of MD signs and symptoms within the group that they examined. • We consider that Dr. Harada's follow-up clinical evaluation should be seen as a preliminary study showing the need for a comprehensive epidemiologic study that would include all of the known outcomes of mercury exposure and could take into account co-morbidity from other diseases, such as diabetes and /or alcohol and test for possible interactions. Such a study should also take into account the presence of other contaminants. For this study it would be most useful to have all of the results of hair and blood sampling by Health Canada, Dr. Chan and Dr. Harada, as well as the results of the neurological examinations that were done by Dr. Harada.	我々の結論（チャン博士とメグラー博士による） • 原田医師と彼のチームはこの住人における水俣病の患者数は見積もらなかったが、水俣病の兆候と症状を示した調査対象人数の参加人数に対するパーセンテージを報告した。 • 原田医師のフォローアップ臨床評価は、既に知られていた水銀汚染の全ての結果を含む、包括的な疫学調査の必要性を示す予備調査として見られるべきであり、糖尿病やアルコールとの相互作用の可能性のテスト等、他の疾患との合計疾患率を考慮せねばならない。このような調査は他の汚染物質の存在をも考慮せねばならない。この調査のためにはヘルス・カナダやチャン博士と原田医師による髪の毛や血液のサンプル摂取の結果の全てと原田医師によって実施された神経学に関する調査の結果があれば最も価値あるものとなるであろう。	1483

Question 3: Based on the clinical psychological/psychiatric examinations that Dr. Harada's team performed on people at Grassy Narrows over the years, please comment on whether you agree with the statements of Donnan, 1986, regarding the psychological health impacts of mercury/methylmercury, which statements appear below respecting pages 001492 to 001493 of the November 2014 supplementary GN submissions to the Government of Ontario? In your professional opinion, has exposure to mercury had psychological/psychiatric impacts on the people of Grassy Narrows and, if so, what have been those impacts?	**質問３：原田医師とそのチームがグラッシー・ナローズで長年に渡って行った臨床心理学的・精神学的調査をもとに、1986 年にドナンが述べた、水銀・メチル水銀の心理学的健康の影響について下記のステートメントに貴殿が同意するか否かをコメントしてください。2014 年 11 月にグラッシー・ナローズがオンタリオ州政府に提出した補足提出の 001492 ページと 001493 ページ関連しています。専門家として貴殿は、グラッシー・ナローズの住人は水銀汚染されたことによって心理的・精神的影響を受けたでしょうか。受けたとお考えであれば、どのような影響を受けたのでしょうか。**	
Excerpts from: Grassy Narrows and Earthroots Fourth Supplementary Submission to Devon Wills, Ministry of the Environment on 2012-2022 Whiskey Jack Forest Management Plan IEA Request, dated November 14, 2014 2. PSYCHOLOGICAL HEALTH IMPACTS OF MERCURY "High blood mercury levels contribute to anxiety..." (Donnan, MOE 1986, p.28) "...mental health effects such as anxiety due to mercury contamination in the Wabigoon-English River System have been borne almost entirely by the Native people of the Grassy Narrows and Whitedog Bands." (Donnan, MOE 1986, p.28) The fear and anxiety from knowing they were contaminated was debilitating to many. The threat of mercury poisoning clearly affected the mental health of these people...." (Donnan, MOE 1986, p.31) "[A] reduction in fish mercury levels could help to reduce anxiety and mental trauma experienced by these people." HIGHLIGHTS

- Similarities between the prevalence of complaints in Minamata and Grassy Narrows
- Similarities in neurological findings were also found.
- Quantitative sensory measurements gave similar results for impairments.
- Younger Canadians were less severely affected than older ones.
- Results suggest that subjects from Grassy Narrows had methylmercury poisoning.

Quantitative somatosensory measurements

ABSTRACT

In 1970, fish caught in the English–Wabigoon River system in northwestern Ontario, Canada, were found to be contaminated with mercury coming from a chlor-alkali plant in the province. In the 1970s, patients exhibiting some of the symptoms of the Hunter–Russell syndrome (e.g. paresthesias, visual field constriction, ataxia, impaired hearing, and speech impairment) were reported by some researchers. However attempts to diagnose the patients as suffering from methylmercury poisoning proved to be controversial. In order to research the presence of methylmercury contamination, and show that the patients, through eating contaminated fish, were suffering from methylmercury poisoning, we studied the results of subjective complaints, neurological findings, and quantitative somatosensory measurements gathered in Grassy Narrows Indian Reservation, Ontario, in March, 2010. At that time, the population of the Grassy Narrows settlement was around 900. Ninety-one residents volunteered to be examined. From them, we selected 80 people who were older than 15 years old, and divided them into two groups. Canadian Younger (CY): 36 residents who were from 16 to 45 years old. Canadian Older (CO): 44 residents who were from 46 to 76 years old. We compared them to Japanese Exposed (JE): 88 methylmercury exposed residents from the Minamata district in Japan, and Japanese Control (JC): 164 control residents from non-polluted areas in Japan. Complaints and abnormal neurological findings were more prevalent and quantitative sensory measurements were worse in the two Canadian groups and the Japanese Exposed group than in the Japanese Control group. Complaints, neurological findings and quantitative sensory measurements were similar in Canadian Older and Japanese Exposed. The results for Canadian Younger fell between those of Canadian Older and Japanese Control. These findings indicate that the clinical signs and symptoms of the residents of Grassy Narrows are almost the same as those recorded for Minamata disease in Japan.

1. Introduction

Since the 1960s, a chlor-alkali plant had been releasing waste products contaminated with mercury into the waters of the English–Wabigoon River system in northwestern Ontario, Canada. In the first examples of fish, from the river system, that were contaminated with methylmercury (Bligh, 1970) levels of up to 16 μg/g were reported. Fimreite and Reynolds (1973) found highly contaminated fish with a maximum

methylmercury concentration of 27.8 μg/g in 1970. The contamination in fish there was almost equal to that measured in fish from Minamata Bay, Japan, where a barracuda was recorded as having 23 μg/g in May 1961 (Fujiki and Irukayama, 1979). The average mercury concentrations, measured in 1971, in walleye and northern pike from Ball Lake, English–Wabigoon River, were 1.99 μg/g and 5.05 μg/g respectively (Armstrong and Scott, 1979).

In 2003, results of similar measurements were 0.40 μg/g in walleye and 0.85 μg/g in northern pike (Kinghorn et al., 2007). The concentrations of mercury in fish are declining, but they are still higher than those found in fish in Minamata Bay, Japan, where the average concentration of mercury in fish has been from 0.17 to 0.42 μg/g during the period of 1998-2004. (Kindaichi and Matsuyama, 2005). Residents living in that area of Japan, still continue to be exposed to low levels of mercury from the eating of locally caught fish.

The two First Nations' communities living in Grassy Narrows and Whitedog Indian Reservations became victims of methylmercury poisoning through the consumption of locally caught fish. Patients with some of the Hunter–Russell syndrome symptoms have been reported in these reserves (Harada et al., 1976). Canadian researchers also examined the indigenous residents of the areas. Wheatley et al. (1979) reported that effects associated with methylmercury poisoning were observed, but they concluded that direct impacts on human health were difficult to prove.

Pathological studies of a cat from Whitedog, which exhibited acute neurological symptoms, revealed high mercury levels in the brain similar to those of Minamata disease in Japan (Takeuchi et al., 1977). Another cat from neighboring Grassy Narrows showed no symptoms, but on closer examination it was shown to have high mercury levels in the brain and latent defects caused by methylmercury poisoning (Takeuchi et al., 1977).

Since 2004, more than 60,000 people from the Minamata district have been diagnosed with abnormal neurological symptoms. In many cases, the abnormalities were being reported for the first time since the release of methylmercury contaminated wastewater was stopped in 1968 (Takaoka et al., 2009). In chronic methylmercury poisoning the somatosensory disturbance from cortical damage is specific and sensory disturbance is present either in all four limbs or throughout the body, sometimes with the exception of the face and head. To detect such abnormalities, quantitative sensory measurements are useful (Takaoka et al., 2008). So we carried out a health survey that included the examination of subjective complaints, neurological symptoms, and quantitative sensory measurements in Grassy Narrows, Ontario, Canada, in 2010 and tried to reassess the effect of methylmercury in this area.

2. Materials and methods

2.1. Subjects

The study was carried out in March 2010 in Grassy Narrows, Ontario, Canada. We contacted a Grassy Narrows support group and asked for their help. They informed the indigenous population of our coming survey to detect any health effects from methylmercury poisoning and asked for volunteers to take part in the study. The Chief of Grassy Narrows First Nation went on the local radio to ask for volunteers for our research. Posters, informing of our coming research project and our wish for volunteers, were displayed in the band office and a local store. Of the approximately 900 residents, 91 volunteered to be examined. We selected 80 residents, who were older than 15, for the study. Subjects were informed verbally and in writing about the examination method, how the data would be used and that their confidentiality would be protected. Each participant gave their written consent.

We divided them into two groups. (1) Group Canadian Younger (CY): consisted of 36 residents who were from 16 to 45 years old (M/F = 18/18, 34.4 ± 9.5 years old). (2) Group Canadian Older (CO): consisted of 44 residents who were from 46 to 76 years old (M/F = 19/25, 57.5 ± 8.1 years old).

We studied subjective symptoms, neurological findings and carried out four quantitative sensory measurements (including minimal tactile sensation, vibration, position sense, and two-point discrimination) among the 80 residents. In order to assess the state of health of the residents of Grassy Narrows, we compared them to a group of Japanese residents who had also been exposed to methylmercury as well as a group of Japanese control residents. These residents were the same people we had used as subjects in our previous study (Takaoka et al., 2008).

(3) Group Japanese Exposed (JE): was comprised of 88 randomly selected Japanese subjects. They were chosen from residents of the Minamata area who had been exposed to methylmercury and who had been included in our former study at the Minamata Kyoritsu Hospital and the Kyoritsu Neurology and Rehabilitation Clinic between November 2004 and April 2005. Their ages matched those of the corresponding Canadian group but the genders could not be matched exactly (M/F = 38/50, 59.0 ± 7.5). They answered a detailed questionnaire and were given a neurological examination including the same four quantitative sensory measurements as we performed in Canada. All of them were born before 1969. In our former study, we separated the subjects into those with and without neurological or neurologically related diseases, but we found that there was little difference between those two groups. So in this study, Group JE included subjects both with and without such related diseases.

(4) Group Japanese Control (JC): consisted of 164 residents who lived in other districts, e.g. around Fukuoka City, Kumamoto City, and Kagoshima City, aged between 40 and 79. In the control group, people who had lived around Minamata City or who suffered from a neurological disease or a neurologically related illness were excluded. The control subjects were examined between February and May 2006 (M/F = 67/97, 58.4 ± 11.6).

2.2. Epidemiological conditions and questionnaire on complications

The questionnaire, both in Canada and Japan, included questions to determine the subject's exposure to methylmercury and asked for information regarding place of residence, dietary habits, occupational history, medical complications and the health and medical histories of family members.

The questionnaire on complaints for the Canadian groups (CO and CY) consisted of 47 questions related to sensory impairment (7 items), somatic pain (4), visual impairment (3), hearing impairment (3), tasting and smelling problems (3), in-coordination of the extremities (4), other movement impairment (11), vertigo and dizziness (4), general complaints (2), and mental and intellectual problems (6).

The questionnaire on complaints for the Japanese groups (JE and JC) consisted of about 50 questions. We selected 35 relevant questions from the Japanese questionnaire and used them in the Canadian one. They were as follows: sensory impairment (4 items), somatic pain (3), visual impairment (3), hearing impairment (3), tasting and smelling problems (3), in-coordination of the extremities (5), other movement impairment (4), vertigo and dizziness (4), general complaints (2), and mental and intellectual problems (4).

In answer to questions on health complaints, subjects were asked to select one of 4 possible choices. 1) Yes, always, 2) Yes, sometimes, 3) Yes, in the past but not at present, and 4) No, never. The prevalence of each complaint was calculated for each group and then compared between the four groups. All subjects completed the questionnaire before their medical examination. Subjects who could not complete the questionnaire by themselves were asked the questions verbally. All questionnaires were reviewed prior to the examinations.

2.3. Standard neurological examination

A standard neurological examination was carried out on 32 of the 36 subjects in Group CY and on all 44 subjects in Group CO. Dysarthria, auditory disturbance, visual constriction, finger–nose test with the eyes open and closed, diadochokinesis, heel–shin test, gait disturbances, tandem gait test, Mann's test, balancing on one foot with eyes open and closed, and superficial sensory disturbance (touch and pain) were used and tested for. The examination methods and criteria were almost the same as the former study (Takaoka et al., 2008).

Dysarthria, auditory disturbance, visual constriction, postural hand tremors, gait disturbances and Romberg's sign were judged to be either present or absent. Dysarthria, auditory disturbance, and visual field constriction were judged by the examining physician without using special instruments. Tunnel vision was considered to be present when the confrontation test showed a lateral field of vision of 80° or less.

Limb and truncal ataxia were judged as being either absent, mildly abnormal or moderately to severely abnormal. The results of the finger–nose test and the heel–shin test were judged to be positive not only when there was constant dysmetria or decomposition but also when there was uncertain dysmetria, decomposition, or very slow movement involved. Dysdiadochokinesis was judged to be present from when there was a constant abnormality to when there was an uncertain abnormality or slow movement. Tandem gait disturbance was judged as present not only when the subject could not walk more than five steps but also when they could walk five steps but were unstable. In the balancing on one foot test, disequilibrium was judged as present when it was impossible to balance more than 3 s or when the subject was unstable, but could keep their balance for more than 3 s.

The examinations were carried out in Canada by one neurologist and four psychiatrists. The neurologist and two of the psychiatrists had previous experience in carrying out these tests from earlier examinations of Minamata disease patients. The other two psychiatrists had been briefed and trained to carry out the tests. In Japan, Group JE was examined by six physicians and one neurologist and Group JC was examined by forty-five physicians, several of whom were neurologists.

Because there was not enough data collected from Group JE for the finger–nose test with eyes closed, Mann's test, Romberg's sign or balancing on one foot with eyes closed test, we excluded that information from our calculations.

2.4. Quantitative sensory measurements

Four categories of tests were used in the quantitative measurement of the somatosensory system. All four categories were the same as in the former study (Takaoka et al., 2008).

2.4.1. Assessment of minimal tactile sense

The minimal tactile sense was measured by the Semmes–Weinstein monofilament test. Twenty kinds of filaments from 0.008 to 300 g were used. Subjects were tested with eyes closed after receiving clear instructions on which locations would be tested. Each filament was pushed until it bent about 90° for about a second. The threshold was the smallest size filament which a subject could feel as touch. The trial was performed starting from a smaller size filament and then gradually increasing the size.

Each filament was tested only once except when the subject was unsure. In that case the examiner, using the same filament, repeated the test an odd number of times and selected the dominant response. If a subject could not detect the maximum filament (300 g), we defined the threshold as 400 g for calculation. Testing was carried out on the lower lip, upper chest and ventral sides of both index fingers and big toes.

2.4.2. Vibration sense

Vibration sense was measured by using a 128 Hz tuning fork. The vibration test was carried out on the middle or upper sternum, the radial side of both wrists and the fibular side of both ankles. Subjects were told to indicate when they no longer could feel the vibrations. The examiner simultaneously struck a tuning fork and started a stopwatch, then placed the base of the fork against the area to be tested. The time interval until the subject reacted was recorded.

2.4.3. Position sense

The testing of position sense was carried out on subjects with their eyes closed. A ruler with a millimeter scale was used. Tests were carried out on the subject's index fingers and big toes. A ruler was placed vertically alongside the digit. With the digit held horizontally, the zero point was the position of the digit's nail on the ruler's scale. The examiner held the digit by its sides and moved it either up or down, holding the position for about 1 s. The subject was asked to indicate whether they felt the movement and if it was up or down. The upward or downward movement started from 5 mm from the zero point and was considered to be the minimum value. The movement was increased in 5 mm increments and the subject's threshold distance was recorded.

Each trial was carried out once for each distance except when the subject was uncertain. In that case the examiner would repeat the test again for an odd number of times and choose the dominant response. If the subject could not feel the maximum movement, the threshold was defined as the maximum distance plus 5 mm.

2.4.4. Two-point discrimination

The two-point discrimination test was carried out on subjects while their eyes were closed. A drafting divider, with the legs set at different distances, was pressed against the subject's skin at an angle of 30 to 45° to a depth of between 1 and 2 mm for about 1 s. The distances between the points used in the test were 1, 2, 3, 4, 5, 6, 8, 10, 12, 15, 20, 25, 30 and 36 mm. The threshold recorded was the shortest distance at which a subject answered correctly. This method was performed on the lower lip and the ventral side of each index finger. If the subject was unable to detect the maximum distance of 36 mm, the threshold was defined as 40 mm for calculation purposes.

In testing Groups CO and CY, the "Yes/No" method was used. However, when a subject felt that 1-point stimulation was actually 2-point stimulation, they were re-tested using the "2-alternative, forced-choice method". In Groups JE and JC the "2-alternative, forced-choice method" was used exclusively.

2.5. Statistical methods

All the calculations were performed using MS Excel and SPSS. Chi square analysis was used in MS Excel when the prevalence was compared, and t-test was used in MS Excel when the average was compared. The correlations were calculated by SPSS.

When we calculated the minimal tactile sense, we converted the grams to the evaluator size using the equation: Evaluator size = log([gram]) + 4.

3. Results

3.1. The subjects' backgrounds

The age and sex of the subjects are shown in Table 1. The age and sex in Groups CO, JC and JE were not statistically different. The age of Group CY was less than the other groups.

From Table 2, we can see that 86% of Group CO and 83% of Group CY answered the question on how they obtained fish and over 60% of Groups CO and CY answered that they are catching fish by themselves. Also from Table 2, we can see that 41% of Group JE and 1% of Group JC

Table 1
Age and sex of each group.

	Age	n (M/F)
Group CO	57.5 ± 8.1	44 (19/25)
Group CY	34.4 ± 9.5	36 (18/18)
Group JE	59.0 ± 7.5	88 (38/50)
Group JC	58.4 ± 11.6	164 (67/97)

belonged to a fisher family. Ninety-three percent of Group JE and 25% of Group JC ate fish every day.

Table 3 shows the relevant medical history of Group CO and Group CY. The information was collected through interviews. On the question of hypertension, although some subjects had no recorded history of hypertension, high blood pressure was detected during the tests. If we detected a systolic pressure of 170 or more or and diastolic pressure of 110 or more in a subject, we recorded that hypertension was present. Some neurological or neurologically related diseases were found in 47 subjects (53%) of Group JE. No neurological or neurologically related diseases were found in Group JC.

3.2. Questionnaire on medical complaints

Medical complaints reported from each group are shown in Table 4, and the p-values by chi square among the four groups are shown in Table 5. In general, the prevalence in both "Yes, always" and "Yes, always" + "Yes, sometimes" in Groups JE, CO, and CY was statistically higher than Group JC. In general, the prevalence in Group JE and Group CO was similar. For most of the complaints Group CY showed a lower prevalence than Group CO.

The questionnaire consisted of questions related to specific and non-specific symptoms in the methylmercury polluted area. Specific symptoms included numbness, difficulty in speaking, fine-finger tasks, buttoning, losing slippers while walking, difficulty in differentiating tastes, detecting smells etc. Non-specific symptoms included headaches, forgetfulness, general fatigue, and so on. In specific symptoms, the prevalence of the answer "Yes, always" + "Yes, sometimes" was lower in Table 4. A tendency to a similar prevalence was observed both in specific and non-specific symptoms.

The correlation efficient among four groups was shown in Table 7. In "Yes, always" answers, the correlation between Groups JE and CO was highest, and was followed by the one between Groups CO and CY. In "Yes, always" + "Yes, sometimes" answers the correlation between Groups CO and CY was highest, and was followed by the one between Groups JE and CO and between Groups JE and CY.

Table 2
Fish sources and frequency of ingestion.

In Canada	Group CO	Group CY
Self-caught fish	28/44 (64%)	24/36 (67%)
Fish caught by relatives and friends, purchased etc.	30/44 (68%)	22/36 (61%)
A combination of both the above	38/44 (86%)	30/36 (83%)
In Japan	**Group JE**	**Group JC**
Fishermen	10/88 (11%)	0/164 (0%)
Fishermen's families	36/88 (41%)	1/164 (1%)
Sport fishing/recreational fishing	62/88 (70%)	17/161 (11%)[b]
Daily ingestion	81/87 (93%)[a]	40/157 (25%)[c]
Ingestion more than once a week	85/87 (98%)[a]	119/157 (76%)[c]

[a] Datum for 1 person was missing.
[b] Data for 3 persons were missing.
[c] Data for 7 persons were missing.

Table 3
Complications in Canadian subjects.

	Group CO	Group CY
Hypertension	15 (34%)	16 (44%)
Diabetes mellitus	8 (18%)	3 (8%)
Stroke	3 (7%)	1 (3%)
Lung diseases	0 (0%)	1 (3%)
Stomach diseases	6 (14%)	1 (3%)
Heart diseases	1 (2%)	0 (0%)
Orthopedic diseases	7 (16%)	4 (11%)
Psychiatric diseases	3 (7%)	1 (3%)

3.3. Neurological examination

The neurological findings for each group and p-values by chi-square among the four groups are shown in Table 6. The prevalence was generally highest in Group JE, and the prevalence of all the findings of Groups JE and CO was statistically higher than Group JC. All the findings of Group CY were less prevalent than Group CO, and seven of twelve findings of Group CO showed statistically higher prevalence than Group CY.

The most prevalent findings in Groups CO are tandem gait abnormality and somatosensory disturbances of pain and touch, followed by hearing impairment, truncal ataxia other than tandem gait abnormality, upper extremity ataxia (finger–nose test and diadochokinesis), and lower extremity ataxia (heel–shin test). The prevalence of visual constriction or dysarthria was lower. Although the orders of prevalence for the positive findings were different, the tendencies of the abnormalities were similar between Groups CO and JE.

Correlation among four groups was shown in Table 7. Correlations between Groups JE and CY, Groups CO and CY, and Groups JE and CO were higher than those between Group JC and other three groups, and p-values were lower.

3.4. Quantitative sensory measurements

3.4.1. Minimal tactile sensitivity using the Semmes–Weinstein monofilament test

Thirty-three subjects (75%) of Group CO and 24 subjects (67%) of Group CY were examined. One set of data for the lower lip in Group CO and one set of data for the left and right big toes in Group CY were absent. 84 of 88 subjects (95%) in Group JE (in which three sets of data were missing for the lower lip) and all 164 subjects of Group JC were examined and calculated.

Fig. 1 shows the results of the minimal tactile sensitivity using the Semmes–Weinstein monofilament test. The results were worst in Group CO, and there were distinct statistical differences between Groups CO, CY, and JC. Group JE was, in general, positioned between Groups CO and CY.

3.4.2. Vibration sense

Thirty-five subjects from Group CO and 25 subjects from Group CY were examined. Two subjects from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 33 subjects (75%) from Group CO and 24 subjects (67%) from Group CY were used in the calculation. Three sets of data for the right ankle and 4 sets of data for the left ankle were absent for Group CO. All 88 subjects of Group JE and all 164 subjects of Group JC (in which one set of data for the chest and one set of data for the left and right ankles were absent) were examined and calculated.

Fig. 2 shows that the vibration sense was worst in Group JE, followed by Group CO, Group CY and Group JC. Most of them had statistical differences between each other.

3.4.3. Position sense

Twenty-eight subjects from Group CO and 24 subjects from Group CY were examined. One subject from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 27 subjects (61%) from Group CO and 23 subjects (64%) from Group CY were used in the calculation. One set of data for the left and the right big toe, both upward and downward movements, was absent for Group CO. Eighty-seven subjects from Group JE (in which one set of data for both big toes in both directions was absent) and all 164 subjects of Group JC were examined and calculated.

Fig. 3 shows that the position sense was worst in Group JE, followed by Group CO, Group CY, and Group JC. Although there were some exceptions, most of the groups had statistical differences.

3.4.4. Two-point discrimination

Thirty-four subjects from Group CO and 25 subjects from Group CY were examined. Two subjects from Group CO and one subject from Group CY were unable to carry out the test correctly and were excluded from the results. Consequently, the results of 32 subjects (73%) from Group CO and 24 subjects (67%) from Group CY were used in the calculation. 87 of 88 subjects (99%) from Group JE and all 164 subjects of Group JC (in which one set of data for the right index finger was absent) were examined and calculated.

Fig. 4 shows that the position sense was worst in Group JE or Group CO, followed by Group CY and finally Group JC. Most of them had statistical differences, except for the results for index fingers when comparing Group JE with Group CO.

4. Discussion

Our results show that subjective complaints were most prevalent in Group JE, followed by Groups CO, CY and JC. Similar and high prevalence of more specific complaints from methylmercury poisoning between Groups JE and CO suggest that these similarities are mainly related to methylmercury poisoning. The increase of non-specific complaints, which was found in Group JE, was also observed in Group CO.

The high prevalence of somatosensory disturbance and following ataxic movement in Groups JE and CO suggests that those two groups are similarly affected by methylmercury and Group CY is affected to a smaller extent by methylmercury. Harada et al. (1976) conducted health surveys on 89 indigenous inhabitants of Grassy Narrows and Whitedog and found sensory disturbance (47.6%), abnormality in visual field (18.0%), impaired hearing (44.9%), ataxia (9.0%), and dysarthria (5.6%). These findings together with the Hunter–Russell syndrome suggest methylmercury pollution in these communities.

Except for the high prevalence of tandem gait abnormality and hearing loss, the pattern of prevalence is almost the same as our study from the Minamata area in the 1970s (Fujino, 1994). Harada and his colleague visited Grassy Narrows in 2002 (Harada et al., 2005a) and Grassy Narrows and Whitedog in 2004 (Harada et al., 2005b). In 2002, glove and stocking type of sensory disturbance (54.4%), tunnel vision (10.5%), ataxia (12.3%) and impaired speech (12.3%) were observed in 57 subjects (Harada et al., 2005a). Combining the results of both studies, 2002 and 2004, glove and stocking type sensory disturbance was found in 65.1% of the cases, tunnel vision in 10.8%, ataxia in 25.1% and impaired speech in 6.9% of the 175 subjects (Harada et al., 2005b). As the criteria used for determining ataxia was not described in those papers, it is possible that the actual percentage could be greater than the papers suggested. We show the raw data for ataxic movement in this study.

Our present study differs from the former studies of 1975, 2002 and 2004, in that quantitative measurements of somatosensory disturbance were added to the study. The results of two-point discrimination sensitivity of the lower lip, vibration sense and position sense in big toes were also worse in Group JE, followed by Groups CO, CY and JC. Somatosensory acuity was most impaired in Group JE. Whereas minimal tactile sensitivity of the lower lip and left big toe were worst in Group CO, followed by Groups JE, CY and JC. The reason for these differences is, as yet, unascertained. As to two-point discrimination, the "Yes/No" method was used in testing Groups CO and CY, and the "2-alternative, forced-choice method" was used in testing of Groups JE and JC. But, in our experience, there were no great differences between results of these two methods.

Quantitative measurements showed that somatosensory disturbance, showing a similar pattern, was present in all tested body areas. These patterns are assumed to be the characteristics of somatosensory disturbance due to a uniformly injured central nervous system, especially the sensory cortex.

The similarity in the symptoms of abnormalities, neurological findings and quantitative measurements in Groups JE and CO were assumed to be produced by methylmercury poisoning. The intermediate abnormalities in Group CY suggest a milder and continuing effect of methylmercury poisoning in the younger generations of this area.

There are some limitations in this study. The first one is that the subjects in the study consisted of applicants who volunteered for the examination. The subjects in Groups JE, CO and CY ate a lot of fish, but the subjects in Group JC ate less fish. Also the lifestyle and occupations of the Japanese and the Canadian subjects are likely to be quite different. Also, the lifestyle and occupations were not the same in the two Japanese groups JE and JC.

Secondly we had no control area in Canada. Instead, we compared the Canadian results with the results from a control area in Japan, as well as from an exposed area in Japan.

Thirdly, there can be other factors involved which can affect the findings. In Groups CO and CY, some neurological diseases were found which confused the analysis of the test results. In order to overcome this limitation, we tried to compare a wide range of symptoms and complaints, neurological findings and quantitative measurements.

In the earlier study in Japan, we found that some complaints, symptoms, neurological findings, and quantitative measurements recorded could be affected by the presence of certain other neurological diseases. However, the similar patterns of symptoms, neurological findings, and quantitative sensory measurements cannot be explained without taking

Table 7

into account the possibility of the presence of methylmercury poisoning (Takaoka et al., 2008).

After Harada's paper in 1976, the health effects of methylmercury on indigenous Canadians (First Nations) were reported by Canadian researchers. Barbeau et al. (1976) reported that he discovered symptoms like Minamata disease patients in Quebec, but he soon modified and toned down his conclusions. Shephard (1979) admitted the higher exposure in Canadian Indians and insisted that there was no agreement on the clinical diagnosis of mercury poisoning. But no conclusive human health-related data of Canadian Indians were presented by them. Wheatley et al. (1979) reported that they failed to prove abnormalities attributable to methylmercury. But his study in 1979 was based on clinical and pathological test results taken from only one male Cree Indian.

In north-western Quebec, McKeown-Eyssen and Ruedy (1983) studied individuals from the Cree First Nation and reported incoordination (15.4% in males/6.5% in females in Mistassini, 44.2% in males/26.5% in females in Great Whale), abnormal perception of sensations (5.7% in males/4.3% in females in Mistassini, 9.3% in males/2.1% in females in Great Whale). The results for subjects who had visual field scores of over 55° were 16.0% in males and 19.4% in females in Mistassini, and 0.7% in males and 15.5% in females in Great Whale. Although the patterns of abnormalities are very different from our results, the presence of these abnormalities could suggest milder methylmercury poisoning. The Canadian researchers did not, however, come to this conclusion. It would appear that they did not follow up and observe the individuals for a longer period of time, which is unfortunate. In our new Minamata disease cases, observed from November 2004 to April 2005, about half of them were considered to have had their first abnormalities after 1968, the year when the Chisso Company ceased to release methylmercury contaminated industrial wastewater (Takaoka et al., 2009).

Spitzer et al. (1988) found no abnormalities in north-western Quebec when they compared people from the Cree First Nation with a control group. In this study, the exposed group (SDD: The Self Designated Disease Group) and other three control groups were compared. Visual constriction was observed in 4.9% of SDD and in 0.0–1.7% of other groups. Peripheral sensory disturbance (written as "peripheral neuropathy" in the paper) was observed in 9.9% of SDD and in 1.5–3.1% of other groups. There was a higher tendency in the prevalence in SDD, but there was no statistical difference between SDD and other groups.

In examining the Cree people, McKeown-Eyssen et al. (1990) emphasized inter-observer variation. It is more important, however, to do the same examination in the control area and to set criteria for judging the results of the examination, rather than to repeat an examination in the same group. Even though there were some variations and differences between the results obtained by the screener and the results of the neurological examination by the neurologist, e.g. prevalence of tremor (screener 40.2%, neurologist 29.9%) and incoordination (screener 22.8%, neurologist 15.4%) in men in Mistassini, they were still high. They also had differences in criteria when identifying neurological abnormalities, but it should be possible to set standard criteria for the assessment of the neurological findings similar to our methods.

Changeability of neurological functions is quite common in cases of Minamata disease. In Minamata disease the range of four limb

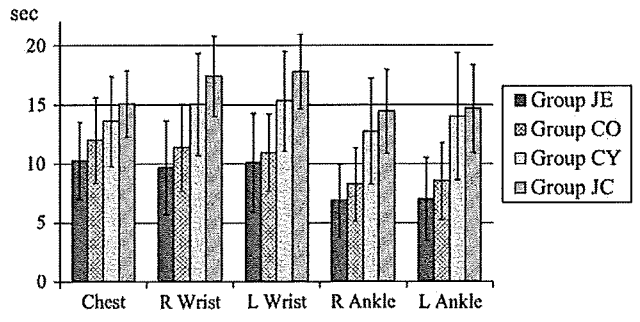

Fig. 2. Threshold for vibration sense — group comparisons. JC, JE: $p < 0.01$ (all locations), JC, CO: $p < 0.01$ (all locations), JC, CY: $p < 0.01$ (bilateral wrist), $p < 0.05$ (chest and R. ankle), n.s. (L. ankle), JE, CO: $p < 0.01$ (chest), n.s. (L wrist), $p < 0.05$ (other locations), JE, CY: $p < 0.01$ (all locations), and CO, CY: n.s. (chest), $p < 0.01$ (all other locations).

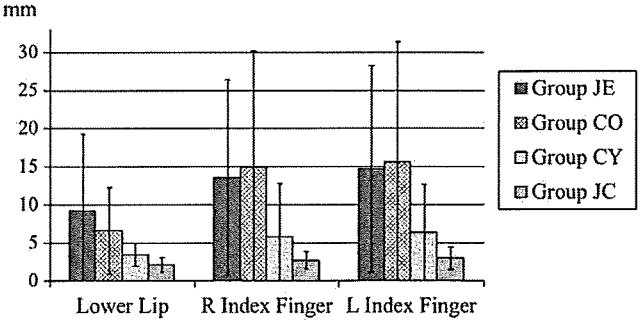

Fig. 4. Threshold for two-point discrimination — group comparisons. JC, JE: $p < 0.01$ (all locations), JC, CO: $p < 0.01$ (all locations), JC, CY: $p < 0.05$ (R index finger), $p < 0.01$ (other locations), JE, CO: $p < 0.05$ (lower lip), n.s. (other locations), JE, CY: $p < 0.01$ (all locations), and CO, CY: $p < 0.01$ (all locations).

somatosensory disturbance is changeable. Uchino and Araki (1984) reported on 100 cases of Minamata disease. In 77 of the 100 cases the examination for superficial sensory disturbance was carried out from 2 to 5 times, and 63 of the 77 cases (82%) were recorded as "unstable type" in which the area of the body showing somatosensory disturbance changed. The most important factor in showing the effect of environmental pollution on the inhabitants of an area is the ability to gather data and information from both the people exposed to the pollution and from a control group which has not been exposed.

There are some other Canadian studies about the exposure to methylmercury (Wheatley and Paradis, 1996; Wheatley et al., 1997; Wheatley and Paradis, 1998), but there are few that take into account epidemiological human health data. Wheatley (1996) stressed that the people of the First Nations understanding of mercury contamination is influenced by their holistic concepts of health and environment. But there was too little physical data available to corroborate this concept. Without the presence of human physical data, we cannot evaluate psychological, social and spiritual values of health.

5. Conclusions

The data collected from methylmercury-exposed indigenous residents of Grassy Narrows suggest that they were poisoned by methylmercury. The health abnormalities also appear to exist in a milder form in the younger generations from Grassy Narrows.

Information on funding sources

The study was conducted partly with funding from Grants-in-Aid for Scientific Research of Japan Society for the Promotion of Science (JSPS) (No. 20330118). The title of the funding is "Studies on the reappraisal of the real situation of Minamata disease damages and their social impact in the past half-century."

Conflict of interest

There is no conflict of interest in this study.

Acknowledgment

We, the authors, would like to express our thanks to the late Masazumi Harada of the Open Research Center for Minamata Studies, Kumamoto Gakuen University, for his planning and involvement in carrying out this research, by dedicating this paper to his memory.

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Shigeru Takaoka. I live in the City of Minamata in the Prefecture of Kumamoto.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

AFFIDAVIT OF TADASHI FUJINO

I, TADASHI FUJINO, of the City of Kumamoto, in the Prefecture of Kumamoto, Japan MAKE OATH AND SAY AS FOLLOWS:

1. I am a medical doctor specializing in psychiatry and neurology at Kumamoto Hospital, in the City of Kumamoto, in the Prefecture of Kumamoto. I have considerable clinical experience examining patients exposed to mercury in Minamata, Japan. At various times, over several decades, I also undertook, with a team of researchers lead by the late Dr.

Masazumi Harada, many clinical examinations of men, women, and children suspected of being exposed to mercury in Grassy Narrows, Ontario, Canada. I have written extensively about my clinical investigations in both countries in a number of medical and scientific peer-reviewed journals. A copy of my curriculum vitae is attached to Exhibit "A" of the affidavit of Shigeru Takaoka for this proceeding.

2. In December 2015 I, along with my colleagues Drs. Shigeru Takaoka and Akitomo Shimoji were asked by counsel for Grassy Narrows First Nation to answer certain questions on medical-psychological/psychiatric issues pertaining to mercury exposure at Grassy Narrows. The questions and our answers to them appear as part of our May 2016 expert report attached as Exhibit "A" to the affidavit of Shigeru Takaoka.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "A" to my Affidavit.

SWORN BEFORE ME in the City of Fukuoka, in the Prefecture of Fukuoka, Japan, this ___ day of _____, 2016.

A Commissioner, etc.

藤野糺の宣誓供述書

私、日本国熊本県熊本市在住の藤野糺は下記のことを宣誓供述致します。

1. 私は熊本県熊本市にある熊本病院で精神科と神経内科を専門としている医師です。私は日本の水俣において水銀汚染された患者の住民健診の経験が豊富であります。数十年に渡り、何度も原田正純医師率いる調査チームと共にカナダ・オンタリオ州グラッシー・ナローズで水銀汚染されたと疑われる男性女性児童の住民検診を多く手がけました。両国において臨床研究について広範囲にわたり論文を執筆し、それらは論文審査のある多くの医学科学専門誌で発表されました。私の履歴書はこの訴訟のために、高岡滋氏の宣誓供述書の証拠品Aに添付されています。
2. 2015年12月、私と同僚の高岡滋医師、下地明友医師はグラッシー・ナローズ・ファースト・ネーションの弁護士からグラッシー・ナローズにおける水銀汚染に係る医学的、心理学的、そして精神的影響に関するいくつかの質問に回答するように依頼されました。質問と回答は高岡滋氏の供述宣誓書に証拠品Aとして添付されている2016年5月専門家報告書の一部として記載されています。
3. 私の専門家全責任承認フォーム1部が証拠品Aとして私の供述宣誓書に添付されています。

AFFIDAVIT OF AKITOMO SHIMOJI

I, AKITOMO SHIMOJI, of the City of Kumamoto, in the Prefecture of Kumamoto, Japan MAKE OATH AND SAY AS FOLLOWS:

1. I am a medical doctor, neuro-psychiatrist, and professor at Kumamoto Gakuen University, in the City of Kumamoto, in the Prefecture of Kumamoto. Along with a team of researchers lead by the late Dr. Masazumi Harada, I participated in clinical evaluations of patients exposed or suspected of having been exposed to mercury in Grassy Narrows,

Ontario, Canada. Based on my clinical experience in Japan, I also have authored or co-authored several articles that have been published in peer-reviewed medical and scientific journals on the subject of exposure to mercury. A copy of my curriculum vitae is attached to Exhibit "A" of the affidavit of Shigeru Takaoka for this proceeding.

2. In December 2015 I, along with my colleagues Drs. Shigeru Takaoka and Tadashi Fujino were asked by counsel for Grassy Narrows First Nation to answer certain questions on medical-psychological/psychiatric issues pertaining to mercury exposure at Grassy Narrows. The questions and our answers to them appear as part of our May 2016 expert report attached as Exhibit "A" to the affidavit of Shigeru Takaoka.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "A" to my Affidavit.

SWORN BEFORE ME in the City of Kumamoto, in the Prefecture of Kumamoto, Japan, this ___ day of _____, 2016.

A Commissioner, etc.

下地明友の宣誓供述書

私、日本国熊本県熊本市在住の下地明友は下記のことを宣誓供述致します。

(AS)
JOH
2016-5-2

1. 私は神経精神科医であり、熊本県熊本市にある熊本大学(学園)の教授でもあります。故原田正純医師率いる調査チームと共にカナダ・オンタリオ州グラッシー・ナローズにおいて水銀汚染された又は水銀汚染が疑われた患者の臨床評価に参加しました。日本における臨床経験に基づき、私は水銀汚染に関する論文を執筆・共同執筆し、それらは論文審査のある医学科学専門誌で発表されました。私の履歴書はこの訴訟のために、高岡滋氏の宣誓供述書の証拠品 A に添付されています。

2. 2015 年 12 月に私と同僚の高岡滋医師、藤野糺医師はグラッシー・ナローズ・ファースト・ネーションの弁護士からグラッシー・ナローズにおける水銀汚染に係る医学的、心理学的、そして精神的影響に関するいくつかの質問に回答するように依頼されました。質問と回答は高岡滋氏の供述宣誓書に証拠品 A として添付されている 2016 年 5 月専門家報告書の一部として記載されています。

3. 私の専門家全責任承認フォーム 1 部が証拠品 A として私の供述宣誓書に添付されています。

Justin Podur, York University

Logging and Forest Fire Risk in Boreal Forests: A Letter

Justin Podur
November 5, 2021

[I am an Associate Professor at the Faculty of Environmental and Urban Change at York University in Toronto. In recent years I have taught courses with titles like: Geographic Information Systems, Environmental Analytics, and Sustainable Environmental Management. My M.Sc. F (2001) and PhD (2006) were in Forestry at the University of Toronto. From 1999, when I started my graduate studies, until 2011, I published in the scientific literature on forest fires (for the past decade I have focused on publishing academic work in other areas). This letter is informed by my own first-hand research in this area as well as my reading of the more recent scientific literature in the field.]

This letter answers three questions.

1. Are fires more likely to start in mature or logged boreal forests?

2. Do logged areas provide effective fire breaks to prevent the spread of boreal forest fires?

3. Does the suspension of logging create increased forest fire risk in boreal forests?

All three of these questions pertain to the idea of a natural or historical fire regime for the boreal forest and the effect of logging in that regime.

1. Are fires more likely to start in mature or logged boreal forests?

No.

The Canadian Forest Fire Behavior Prediction System (FBP System - https://cwfis.cfs.nrcan.gc.ca/background/summary/fbp) "provides quantitative estimates of potential head fire spread rate, fuel consumption, and fire intensity, as well as fire descriptions. With the aid of an elliptical fire growth model, the FBP system gives estimates of fire area, perimeter, perimeter growth rate, and fire behavior at the head, flanks, and back of a fire." These estimates are used by modelers and fire managers in the field in their decision-making about fire management. The FBP Fuel Types are described here – https://cwfis.cfs.nrcan.gc.ca/background/fueltypes/c1. Recently harvested areas would be classified as S1 – Jack or Lodgepole Pine Slash, S2 – White Spruce – Balsam Slash; mature areas would be classified as, for example, C2 – Boreal Spruce, C3 – Mature Jack or Lodgepole Pine.

The conditions for a fire to start or spread in different fuel types can be understood by observations of fire behavior in different boreal fuel types. J. J. Podur & Martell, 2009 studied the fraction of area burned in different FBP System fuel types in 594 large fires in the boreal forest between 1996-2006 and found that "the composition of fuels burned is essentially the same as the composition of fuels available for burning."

In other words, if the weather conditions are conducive to fire spread, fires will start in mature or logged boreal forests without preference.

2. Do logged areas provide effective fire breaks to prevent the spread of boreal forest fires?

No.

In fire management in Ontario, fires are usually fought using water – firelines are constructed around a perimeter using water pumped from a nearby body of water. In rare cases and other jurisdictions, firebreaks can be made using back fires or bulldozer lines.

These firebreaks are different from harvested areas, which become the slash fuel type. As discussed in question number 1, in areas with the slash fuel type, and in young forest areas, fires start and spread at the same rate as in mature forests. Logged and young boreal forests provide no fire protection compared to mature boreal forests.

3. Does the suspension of logging create increased forest fire risk in boreal forests?

No.

It is possible to mitigate fire risk using a series of measures grouped under the label “fire-smart forest management” (Hirsch et al., 2001). Such measures are based on a recognition that fire plays an important ecological role in boreal forests and include allowing fire on the landscape where other values (especially public safety) are not at risk (Shinneman et al., 2012).

But harvesting is not a way to mitigate fire risk.

Additional Discussion

Several studies discuss the relative importance of fuels and weather in fire behavior (e.g. (Bessie & Johnson, 1995), (Hély et al., 2001), (Parisien et al., 2011), (Lydersen et al., 2017)). While several of these, including fire-smart management, emphasize the ecological value of increasing fire on the landscape (e.g. (Parks et al., 2015), (Hirsch et al., 2001)), other authors worry that climate change will overwhelm fire management capacity ((Dieleman et al., 2020), (Whitman et al., 2019), (J. Podur & Wotton, 2010).

While fire weather is known to be the overwhelming factor, it has been pointed out that a complete change of species composition from conifer to deciduous could reduce fire risk, or at least mitigate the increase in fire risk due to climate change. Krawchuk & Cumming, 2011 conducted a simulation study and did find that “forest harvesting resulted in decreased regional fire activity when compared to unharvested conditions”. They note however that in their simulation, “forest composition and age structure was shifted substantially, illustrating a trade-off between management goals to minimize fire and conservation goals.” Terrier et al., 2013 also conducted a simulation study and found that the wholesale conversion of boreal conifer forest to deciduous forest could reduce fire risk, though it would do so at the price of completely changing the ecosystem. In most of Eastern Canada’s boreal forest,

logging has so dramatically altered the ecosystem that restoration efforts would be required to attain the pre-industrial age structure, species mix, and altitudinal gradients ((Boucher et al., 2009). This would seem to make the preservation of existing old-growth forests a priority, at least from an ecological conservation perspective.

Sincerely,

Justin Podur, Associate Professor, York University

1.0 EXECUTIVE SUMMARY

This report, for the Whiskey Jack Forest (the Forest), documents the results of an Independent Forest Audit conducted by KBM Forestry Consultants Inc. All Crown forests in Ontario are required to be audited at least every five years; the requirement for independent audits arising from MNR's Class Environmental Assessment Approval for Forest Management on Crown Lands in Ontario (2003). Regulation 160/04 of the Crown Forest Sustainability Act (S.O. 1994, c. 25) (CFSA) sets out the specific requirements for conducting the audits.

KBM Forestry Consultants Inc. conducted an independent forest audit on the Whiskey Jack Forest for the five-year period April 1, 2004 to March 31, 2009. The audit assessed implementation of the 2004-2024 Forest Management Plan (FMP) and the planning process and approval of the 2009-2012 Contingency Plan. Selected portions of the planning process for the 2004-2024 FMP, the first year of which was a contingency plan, were also audited. The on-site component of the audit occurred from September 14 to 21, 2009. Document review and interviews occurred throughout the audit process. The principal auditees were both Abitibi-Consolidated Company of Canada (ACCC), a subsidiary of Abitibi-Bowater, and the Kenora District and Red Lake District of the Ontario Ministry of Natural Resources (MNR).

During the audit term, the Sustainable Forest Licence (SFL) for the Whiskey Jack Forest was held by ACCC. Circumstances related to closure of the company's newsprint mill in Kenora, Ontario and a protracted dispute between the Crown and Grassy Narrows First Nation over forest management practices on the Whiskey Jack Forest, led the company to make a request to surrender the SFL to the Crown. The Crown accepted the company's completion of its pre-surrender obligations in a letter dated September 29, 2009, at which time the company was given six months to complete all post-surrender conditions. As holder of the SFL during the audit term, ACCC was responsible for virtually all aspects of forest management planning, harvesting, reforestation, and monitoring.

Based on the audit, 21 recommendations were made. Recommendations arise from audit team observations of material non-conformances, or may be developed to address situations in which the audit team identifies a significant lack of effectiveness in forest management activities. All audit recommendations are either directed at MNR or the Forest Manager or both. The Forest Manager represents the equivalent of the SFL holder in terms of contractual obligations. Because the SFL was surrendered by ACCC, MNR is presently the defacto forest manager on the Whiskey Jack Forest. As such, MNR is responsible to address all the audit recommendations directed at the Forest Manager until a new Forest Manager is identified.

The audit team found significant issues with management of the Whiskey Jack Forest, both in planning and in on-the-ground implementation of the plan. The future forest modeled during planning, and the one associated with the selected management alternative, is inconsistent with the natural forest as described in the forest management plan. The differences are magnified by the silviculture program being implemented in that the program is inconsistent with the forest projected by the selected management alternative and is leading the forest even further away from the natural forest condition.

The regeneration methods being practised do not support the plan goal of maintaining current levels of spruce forest and will result in a further departure from what is believed to be the historic forest condition of a spruce dominated forest described in the 2009-2012 Contingency Plan. The resulting forest stands will have a greater hardwood component and lower conifer stocking than projected. This has implications for the achievement of wildlife habitat management objectives for species that rely on the development of conifer dominated cover types.

The increase in hardwood at the expense of conifer is the direct result of the absence of a tending program, beyond a small scale spacing program. This in turn is tied to the protracted dispute with Grassy Narrows First Nation over forest management practices on the Whiskey Jack Forest, including

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

herbicide spraying, and decision not to spray herbicide during the dispute. A lack of tending was identified as a serious issue in the previous Independent Forest Audit. Significant effort and expense will be required to retreat or otherwise manage sites artificially regenerated during the audit term to align them with outcomes projected in the 2004-2024 Forest Management Plan. The audit team also found that Free-to-Grow survey records did not accurately reflect stand attributes; both for the regular survey program and the survey of backlog areas, and therefore needs review.

The audit team found that a pesticide program intended to control an outbreak of jack pine budworm lacked an adequate analysis of alternatives from a cost/benefit standpoint. The audit team recommended that MNR be better prepared to conduct such analyses for future outbreaks.

Improvements were noted in water crossings installations (non-winter) and drainage practices on roads.

The audit team concluded that, with the following critical exception noted below, management of the Whiskey Jack Forest was generally in compliance with the legislation, regulations and policies that were in effect during the term covered by the audit, and MNR met its legal obligations. Forest sustainability, as assessed through the Independent Forest Audit Process and Protocol, will not be achieved unless corrective measures are immediately taken to address the following issues:

Silviculture practices, including a lack of tending of artificially regenerated areas, are leading to reduced stocking of conifer and an increased component of hardwood on the Forest. This trend does not support the management intention of maintaining a conifer dominated forest, as set out in the 2004-2024 Whiskey Jack Forest FMP.

Recommendation 3 of this audit must be satisfied to bring the Whiskey Jack Forest into general compliance.

ACCC has surrendered the SFL for the Whiskey Jack Forest to the Crown; therefore the audit team makes no recommendation on licence extension.

Rod Seabrook, CEA(SFM) EMS(LA)
Lead Auditor, on behalf of the audit team

2.0 TABLE OF RECOMMENDATIONS

Recommendation on Licence Extension
Management of the Whiskey Jack Forest was generally in compliance with the legislation, regulations and policies that were in effect during the term covered by the audit, and MNR met its legal obligations. No recommendation is made as Abitibi Consolidated Company of Canada has surrendered SFL Licence No. 542253 for the Whiskey Jack Forest to the Crown.

Recommendations Directed to Forest Manager / MNR District
Recommendation 1: MNR Kenora District and MNR Red Lake District must ensure that the LCC Terms of Reference for the Kenora and Red Lake LCCs meet the content requirements of the FMPM regarding a protocol for the functioning of multiple LCCs.
Recommendation 2: The Forest Manager must ensure that available survey information (regeneration surveys, Free-to-Grow, silviculture effectiveness monitoring, etc.) is used in the development of the silviculture program in the next FMP.
Recommendation 3: The Forest Manager must ensure that: a) the Silviculture Ground Rules, silviculture exceptions, planned renewal program and actual silvicultural intentions of the next forest management plan support the long term management direction and related silvicultural strategies, b) the connection between strategic and operational silviculture is clearly discussed in the text of the next plan, and c) the operational renewal program aligns with the planned renewal program and supports the long term management direction.
Recommendation 5: The Forest Manager must ensure that, if required, the Natural Benchmark (or equivalent) developed for the next FMP better reflects actual conditions and that, if required, targets/desired levels (or equivalent) for appropriate objectives in the next FMP include consideration for the Natural Benchmark trend line.
Recommendation 6: The Forest Manager must ensure that moose shelter patches are retained as specified in the FMP.
Recommendation 7: The Forest Manager must ensure that operators refine their work methods on fine textured soils to avoid operating during wet or non-frozen periods.
Recommendation 8: The Forest Manager must ensure that the inventory is reviewed and verified for accuracy with respect to Free to Grow records updated during the audit term.
Recommendation 9: The Forest Manager must ensure that site preparation results in the production of planting spots of the quality and quantity appropriate to meet plan objectives.
Recommendation 10: The Forest Manager must ensure that planting of red and white pine occurs on appropriate sites.
Recommendation 11: MNR Kenora District must ensure that all blocks harvested during the audit term are reviewed for slash management and, where established regeneration will not be affected a) slash be piled and burned or otherwise removed to allow regeneration of productive land, or b) if natural regeneration of these areas is not expected, then treat the area to ensure regeneration.
Recommendation 12: MNR Kenora District must ensure that: a) a review is conducted of all areas planted and seeded during the audit term and that fill planting or re-seeding occurs as necessary to support the achievement of FMP objectives, b) a review of all sites harvested during the audit term that are forecast to become conifer-leading forest units is conducted, and that tending occurs where necessary so that plan objectives can be met.
Recommendation 13: The Forest Manager must ensure that seed collection and storage meet the needs of the renewal program.
Recommendation 14: MNR Kenora District must review the Forest Renewal Trust Fund rates particularly for spruce/pine/fir and assign rates appropriate for meeting plan objectives.
Recommendation 15: The Forest Manager must develop a road rehabilitation strategy for the next FMP to ensure that unwarranted roads are rehabilitated and returned to the productive forest landbase.
Recommendation 16: The Forest Manager must develop a monitoring program to ensure that all water crossings installed during the winter are inspected immediately following the first spring thaw after their installation, and incorporate the monitoring strategy into the FMP.
Recommendation 17: The Forest Manager must ensure that the interests of public safety are paramount for establishing pit rehabilitation requirements for all pits at all times.

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

Recommendation 18: MNR Kenora District must ensure that a review of the original field data of the barren and scattered survey occurs and that the inventory is appropriately updated with this information.
Recommendation 19: The Forest Manager must ensure that: a) all information in the Annual Report is confirmed for accuracy prior to finalization, b) future Annual Reports contain all required discussions including progress towards achievement of plan objectives, potential implications of operations on future operations and effectiveness of road use management strategies.
Recommendation 20: MNR Kenora District must ensure that the 2008-09 Year 10 AR is revised to include the following: a) analysis/discussion of changes that may affect future levels, effectiveness and expenditures of renewal and tending operations, b) analysis/discussion of effectiveness of silvicultural treatment packages that are exceptions to the forest management guides, c) review/discussion of needed modifications or refinements to modeling assumptions, d) a summary of progress on implementation of the 1999-2004 IFA Action Plan, e) an update of the inventory and running of SFMM at plan end (2009) to determine objective achievement, f) an update of the 2004-2024 FMP social and economic description, and g) based on the determination of sustainability and the social and economic review, develop recommendations for the next FMP.
Recommendation 21: The MNR Kenora District Manager and the Forest Manager must ensure that the audit action plan and status report comply with all IFAPP submission requirements.

Recommendations Directed to Corporate or Regional MNR
Recommendation 4: MNR Region must develop the capacity to conduct risk based cost benefit analyses of proposed pest management programs in advance of future outbreaks.

3.0 INTRODUCTION

3.1 Audit Process

Independent Forest Audits (IFAs) are a requirement of the Crown Forest Sustainability Act (S.O. 1994, c. 25) (CFSA) and the Forest Management Class Environmental Assessment on Crown Lands in Ontario. Every forest management unit in Ontario must be audited by an independent party at least once every five years. The Independent Forest Audit Process and Protocol (IFAPP) was developed by MNR to provide a comprehensive and consistent method of evaluating forest management activities on Crown land. It serves as a framework that provides a structured approach to evaluating whether or not forest management activities meet the requirements governing forestry practices on Crown land in Ontario.

Within the report the audit team has made recommendations to address instances of non-conformance to a law and/or policy, or an identified lack of effectiveness in forest management activities. Recommendations are listed in the table in the previous section and presented within the main body of the report together with a brief description of the issue leading to the recommendation. A full discussion of the issue, including the link to the IFAPP principle, criteria and audit procedure, associated background information, summary of evidence and conclusion leading to the recommendation is contained in Appendix 1.

All audit recommendations are either directed at MNR or the Forest Manager or both. The Forest Manager represents the equivalent of the SFL holder in terms of contractual obligations. Because the SFL was surrendered by ACCC, MNR is presently the defacto forest manager on the Whiskey Jack Forest. As such, MNR is responsible to address all the audit recommendations directed at the Forest Manager until a new Forest Manager is identified. More detailed information on the audit process and sampling is provided in Appendix 4 of this report.

KBM Forestry Consultants Inc. conducted the IFA on the Whiskey Jack Forest for the five-year period April 1, 2004 to March 31, 2009. Audit team members and their qualifications are presented in Appendix

For Evaluation Only.

6. The audit assessed implementation and selected portions of planning of the 2004-2024 Forest Management Plan (FMP), the first year of which was a contingency plan, and the planning process and approval of the 2009-2012 Contingency Plan. The 2004-2005 Contingency Plan was prepared due to a delay in preparation of the 2004-2024 FMP. The Contingency Plan operating areas were derived from non-contentious areas identified from the FMP. As such, preparation of the Contingency Plans was directly tied to preparation of the FMP.

According to the Contingency Plan proposal for the 2009-2012 Contingency Plan, the Plan was required to synchronize the planning schedules for the Whiskey Jack Forest and the adjoining Kenora Forest to enable the amalgamation of the two forests.

3.2 Management Unit Description

The Whiskey Jack Forest is located in Northwestern Ontario within MNR's Northwest Region. The Forest is administered by MNR Kenora District, with Red Lake District having compliance monitoring and enforcement responsibilities for portions of the Forest north of the English River. During the audit term, the majority of wood harvested from the Forest was processed by facilities in Kenora and Fort Frances with the balance sent to facilities in Ear Falls, Chapple, Dryden, Hudson, Thunder Bay, Longlac and Nipigon. Other communities within and surrounding the Whiskey Jack Forest include Sioux Narrows, Keewatin, and the First Nations of Grassy Narrows, Whitefish Bay, Wabauskang, and Wabaseemoong.

Figure 1 depicts the Forest in relation to Northwestern Ontario and surrounding Forest Management Units and communities.

The Whiskey Jack Forest is approximately 964,000 ha in size. It occurs fully within the Boreal Forest Region of Ontario and forest cover is predominantly jack pine, black spruce, poplar and birch. Red pine and white pine also occur in southern portions of the unit in proximity to Lake of the Woods. Figure 2 illustrates the proportion of production forest by working group, exclusive of barren and scattered areas, and the age class distribution on the Forest at the start of the 2004-2024 FMP.

Soils are mostly sandy to coarse loamy in texture. Fine textured silt and clay soils are associated with approximately 15% of the Forest's area. These types of soils are highly productive but are also susceptible to compaction if care is not taken during forestry operations. Another important feature is the large number and extent of lakes and rivers on the Forest. Production forest accounts for approximately 84% of the total forested land and about 68% of the total forest area.

3.3 Current Issues

Key current issues are summarized below:

1. Industrial wood consumption has declined dramatically. The permanent closure of the ACCC paper mill in Kenora, idling of the Kenora Forest Products sawmill, the decision by Boise Cascade to not take products originating from wood from the Whiskey Jack Forest, together with the severe economic downturn in the forest products industry have combined to significantly reduce actual harvest levels compared to planned levels.

2. There is an ongoing dispute between Grassy Narrows First Nation (GNFN) and MNR over concerns the First Nation has with management of the Whiskey Jack Forest, in particular on areas the First Nation community has declared as traditional territory. During the dispute there has been a virtual halt to logging within the traditional territory and suspension of herbicide spraying under the regeneration program across the Forest.

   A Process Agreement was entered into by GNFN and the Province in 2008 committing the two parties to creating a positive, long-term relationship by reaching agreements that address GNFN's concerns; however, during a meeting between the lead auditor and GNFN representatives of the Forest Management Working Group (FMWG), established under the Process Agreement, the representatives stated that the agreement was not progressing as well as expected. The representatives felt that there is a set agenda and that MNR wants things to fit within established practices, and that nothing new has been forthcoming from the exercise. The representatives also stated that real change needs to occur and emphasized that past audits of the Whiskey Jack Forest did not provide substantial change for the process of forest management. Documentation submitted by GNFN in response to the proposed 2009-2012 Contingency Plan illustrates the depths of the divide between the community and MNR over management of the Whiskey Jack Forest, and the extent to which the community demands direct involvement in decision-making on its traditional territory on the Forest. For example, GNFN believes that setting buffer widths based on slope is simply following the rules and does not make sense ecologically. It is also felt that 30 m wide buffers do nothing for wildlife habitat.

   Forest management planning on the Whiskey Jack Forest is now complicated by the Process Agreement between the two parties that operates according to a separate timetable and has a

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

separate set of expectations, objectives and activities that GNFN requires are resolved before they give consent to further forestry activities within their traditional territory.

3. There was a notable lack of adequate vegetation control that was observed in previous IFAs and has carried into the current audit term. It has led to an increase in the presence of aspen and other forms of vegetation that are competing with conifer regeneration and to a forest composition inconsistent with the long term management direction set for the Forest. This situation is a result of Issue 2, described above, and is accentuated by ACCC's move to the use of lower cost renewal treatments.

4. The wood supply commitment for Weyerhaeuser Trus Joist cannot be met because the reduction in softwood harvest has resulted in a reduction in the harvest of incidental hardwood.

5. Piling and burning of roadside logging slash was not done on many of the blocks logged in 2007 and later. This will result in areas of productive land being unavailable for regeneration if left in their current state.

6. Mechanical site preparation did not provide good block coverage, conifer planting densities were lower than desired and areas seeded to jack pine were generally not successful. As a consequence, many sites will require fill planting to meet FMP objectives.

3.4 Summary of Consultation and Input to Audit

Opportunities were provided throughout the audit process for consultation with and input from auditees and other interested parties. The audit team spoke with staff from MNR, AbitibiBowater, Local Citizen Committee (LCC) members, a wood supply commitment holder, and members of two First Nation communities. In addition, comments were received in response to a questionnaire made available to the public. A summary of the methods and input is provided in Appendix 4.

4.0 AUDIT FINDINGS

4.1 Commitment

The commitment principle is deemed to be met for both the company and MNR, according to the IFAPP, since the Whiskey Jack Forest was certified under the CAN/CSA Z809-02 certification standard for most of the audit term. The company had a written environmental and sustainable forest management policy that was communicated within the organization and available externally. The company's compliance record was considered acceptable. However, recent decisions with respect to the renewal program are leading to changes in forest cover that are not fully consistent with the direction set in the FMP. The FMP, in turn, is not completely aligned with the plan's intention of producing a spruce dominated forest condition similar to that which existed historically. Adjustments in management practices and/or management direction will need to be made to address this issue.

4.2 Public Consultation and Aboriginal Involvement

Notifications to the public met FMP requirements for the 2004-2024 FMP with minor exceptions. MNR maintained a summary of public input in table form; however the record of responses to issues or questions requiring follow-up was incomplete. This was improved for the 2009-2012 Contingency Plan. Overall, records of notices and public input were well organized and maintained. Public consultation for the 2009-2012 Contingency Plan followed the process described in the associated plan proposal and represented an abbreviated version of consultation under a regular forest management plan, with mailouts, published notices to the public, and opportunities for public input on the Draft Contingency Plan at public information sessions being provided.

There were five concerns raised during preparation of the 2004-2024 FMP that had the potential to enter into the issue resolution process. Four of the five were either not pursued or were resolved without

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

pursuing issue resolution. The fifth, initiated by three GNFN trappers, resulted in a request to the Ministry of the Environment (MOE) for an Individual Environmental Assessment (IEA). Extensive documentation exists regarding this issue. The IEA was eventually denied by MOE; however one of the trappers has since launched a law suit, currently before the courts, challenging MNR's authority to manage portions of the Whiskey Jack Forest. There were no requests for issue resolution during preparation of the Contingency Plan.

Requirements for establishment and operation of an LCC were met for both the Kenora LCC and the Red Lake LCC. Regular meetings were held (Red Lake does not meet during the summer) and attendance was generally acceptable. Some interest groups remain unrepresented (e.g. Aboriginal communities); however, efforts are on-going to recruit representatives. Both are longstanding committees with a number of members with extensive experience serving on the committee. Both LCCs had representatives who regularly attended planning team meetings for the 2004-2024 FMP and 2009-2012 Contingency Plan. Terms of Reference were updated as of 2006 for both LCCs; however a protocol was not prepared to address the functioning of multiple LCCs on the Whiskey Jack Forest, as required by the Forest Management Planning Manual (FMPM).

Recommendation 1: MNR Kenora District and MNR Red Lake District must ensure that the LCC Terms of Reference for the Kenora and Red Lake LCCs meet the content requirements of the FMPM regarding a protocol for the functioning of multiple LCCs.

MNR maintains an extensive list of Aboriginal communities and organizations with a potential interest on the Whiskey Jack Forest. Four First Nation communities (Grassy Narrows, Whitefish Bay, Wabauskang, and Wabaseemoong) are either within or adjacent to the Whiskey Jack Forest and as such received separate invitations to participate on the 2009-2012 Contingency Plan Planning Team, with three communities accepting the invitation. The Kenora Métis Council also provided a representative to the planning team.

GNFN has continued to decline to participate in the formal forest management planning process although meetings were held between MNR and GNFN at which components of the Contingency Plan were discussed. A separate process is underway with MNR in an attempt to resolve GNFN community's concerns about forest management and other issues on the Whiskey Jack Forest. Both GNFN and Whitefish Bay First Nation stated in separate letters to MNR their concerns with the 2009-2012 Contingency Plan and dissatisfaction with the forest management planning process. This position was restated during a meeting between Grassy Narrows First Nation representatives on the Forest Management Working Group and the lead auditor. The Working Group was formed as part of the Process Agreement between GNFN and MNR.

There are fundamental differences in the viewpoints between GNFN and MNR regarding forest management principles and practices. It is the audit team's opinion that these differences cannot be resolved without the Province setting aside many of the requirements to manage the Whiskey Jack Forest under the CFSA and the FMPM, and relinquishing significant authority to the First Nation to manage portions of the Whiskey Jack Forest according to the desires of the GNFN community. The audit team further believes that the forest management planning process did not anticipate, nor was it designed to resolve the type of dispute currently being experienced on the Whiskey Jack Forest.

Background information reports were produced for each community; however there has been little to no direct participation by First Nation communities in preparation of the reports. This is related to some extent to differing expectations over the level of funding and effort required to develop the information necessary for forest management planning purposes and differences in viewpoints as to the extent of values protection required.

Wabeseemoong First Nation's principal interests are associated with the Kenora Forest but the community has recently become more involved in forest management planning on the Whiskey Jack

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

Forest. The community is interested in participating in a new cooperative SFL that may involve the eventual merger of the Kenora Forest and Whiskey Jack Forest; two meetings with MNR having been held to date. The community is working on a Traditional Ecological Knowledge project and has been interviewing community members and identifying values such as grave sites and trap lines. Wabaseemoong has its own geographic information system (GIS) that it is using to map these values and also values contained in MNR's database. The community has been involved in tree planting and a few community members also operate logging equipment. The community has received a 9,000 m^3 commitment for pole sized material from the Whiskey Jack Forest and the same amount from the Kenora Forest, and has partnered with a local company to build modular homes designed for northern conditions. Community members have expressed concern over herbicide spraying especially by Hydro on the power line right of way, and there are mixed feelings in the community about logging.

4.3 Forest Management Planning

During development of the 2009-2019 FMP, factors such as the collapse of world financial markets, the closure of the Kenora saw mill and the development of a Memorandum of Understanding between MNR and Grassy Narrows First Nation had significant impact on forest management planning. Through interviews and document review it was determined that there were considerable delays developing the 2009-2019 FMP. In particular there were delays achieving the planning inventory checkpoint and there was division in the planning team regarding the Long Term Management Direction (LTMD) that stalled plan development. These factors were considered in the decision by the MNR District Manager in June 2008 to halt development of the 2009-2019 FMP prior to Regional review/approval of the LTMD. Soon after, it was decided by MNR that a three year Contingency Plan was needed to allow amalgamation of the Whiskey Jack and Kenora Forests (scheduled for 2012) and to deal with the many factors impacting upon forest management planning.

Both the Contingency Plan proposal and the Contingency Plan met the requirements of the FMPM. The Contingency Plan Proposal cites only amalgamation as rationale for the need of a Contingency Plan and despite almost two full years of planning for the 2009-2019 FMP, section 3.4 of the 2009-2012 Contingency Plan notes that "there have been no new planning initiatives on the Forest". Considering the substantial planning that had occurred, the audit team suggests there should have been some mention in the Contingency Plan Proposal and the 2009-2012 Contingency Plan regarding the development of the 2009-2019 FMP, particularly the main issues encountered, and reasons for the plan delays and other factors that led to the decision for a three year Contingency Plan. This information is important to future planners and would provide clarity to the public.

Weyerhaeuser representatives may have a legitimate concern that the delay to develop a new FMP (i.e. abandoning the 2009-2019 FMP for the 2009-2012 Contingency Plan) will further compromise the ability to realize their wood commitments from the Forest. MNR is planning to amend the Contingency Plan if the current allocation is inadequate to meet wood supply commitments.

Area of Concern (AOC) planning for the 2009-2012 Contingency Plan was performed in accordance with the FMPM requirements. Supplemental Documentation 6.6.14 provided detailed discussion for a range of values and included separating similar values because of specific environmental or geographic circumstances to which the values was tied. For example, osprey nests were separated into three AOCs for the development of prescriptions that were distinctly related to environmental and geographic conditions: NE2 – Primary Osprey Nest established prior to operations; NE3 - Primary Osprey Nest in areas previously harvested; and NE4 - Alternate Osprey Nest.

Resource Stewardship Agreements (RSAs) were included in AOC prescriptions developed for tourism operations. Seventeen AOC prescriptions for tourism were included in Sup Doc 6.6.14, the majority of which followed RSA direction negotiated in the 2004-2024 FMP. The 2009-2012 CP explained that RSAs negotiated with ACCC would become obsolete although prescriptions developed therein have been carried forward.

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

There were 45 Silvicultural Ground Rules (SGRs) developed for the 2004-2024 FMP, which followed the requirements of the 1996 FMPM. The same SGRs were used in the 2009-2012 Contingency Plan as stipulated by the approved Contingency Plan Proposal. While the SGRs are a relatively good representation of what is on the Forest, significant issues were found regarding specific components of some SGRs related to over-estimation of expected future conifer and under-estimation of hardwood. Better use of field survey information would assist in addressing this issue.

Recommendation 2: The Forest Manager must ensure that available survey information (regeneration surveys, Free-to-Grow, silviculture effectiveness monitoring, etc.) is used in the development of the silviculture program in the next FMP.

Other, less significant issues found with the SGRs are also summarized in the audit report to aid in the development of the next SGRs.

During the previous IFA the audit team recommended that future forest management plans include thorough silvicultural strategies that support silviculture intentions and are linked to the selected management alternative. However, the 1999-2004 IFA recommendations were not available for the development of the 2004-2024 FMP and the Contingency Plan subsequently developed for the 2009-2012 term is required to use the strategic direction from the 2004-2024 FMP, therefore actions on this recommendation have not yet occurred. Similar, if not greater, discrepancies with regards to the modeled and planned silviculture program were found in the 2004-2024 FMP and the 2009-2012 Contingency Plan. The audit team recommended improvements be made to address these various issues during planning of the next FMP.

Recommendation 3: The Forest Manager must ensure that:

a) the Silviculture Ground Rules, silviculture exceptions, planned renewal program and actual silvicultural intentions of the next forest management plan support the long term management direction and related silvicultural strategies,

b) the connection between strategic and operational silviculture is clearly discussed in the text of the next plan, and

c) the operational renewal program aligns with the planned renewal program and supports the long term management direction.

The audit team inspected approximately 3,000 ha of forest treated over two years by aerial application of a biological pesticide (Btk) to control an outbreak of jack pine budworm. The treated area viewed by the audit team encompassed a marten core that is deferred from harvest to maintain marten habitat and large areas of "interior" old forest. The value of trying to "preserve" the jack pine in marten core areas is questionable. MNR representatives suggest that the main reason this strategy was pursued was to reduce the risk of catastrophic fire and this may indeed have a favourable benefit-cost ratio but the supporting analysis is limited. The evaluation of options lacked rigour and was supported by a minimal level of quantitative analysis. There were also issues in assembling the data at the regional scale to complete a detailed analysis of options. Future outbreaks will surely occur and MNR should prepare for this event by, at the very least, preparing input files for regional level analyses.

Recommendation 4: MNR Region must develop the capacity to conduct risk based cost benefit analyses of proposed pest management programs in advance of future outbreaks.

The 2004-2024 FMP described the selection criteria for harvest, renewal and tending which were consistent with the eligibility criteria. These criteria were thorough, clearly written and ranked in order of importance. Selection criteria in the 2009-2012 Contingency Plan were somewhat consistent with those used in the 2004-2024 FMP but focus was given to operational interests over de-fragmentation and other objectives. Also, some FMPM requirements were not met – documentation regarding how the criteria

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

reflect or are consistent with the SMA and discussion of relative importance of criterion were absent. This documentation should be included in the next FMP.

It was noted that the harvest selection criteria from the Contingency Plan Proposal, which included ensuring that planned and contingency areas from the 2004-2024 FMP were to be first priority for selection and that selections would include only non-contentious areas, were not brought into the text of the 2009-2012 CP. This would have provided better context to the selection of operations in the CP. According to MNR, 97% of the 2009-2012 contingency planned allocation (one year regular harvest area and six months of contingency area) was formerly either planned harvest or contingency harvest from the 2004-2024 FMP. The remaining 3% came from non-contentious areas deemed as optional for harvest in the 2004-2024 FMP.

According to the Contingency Plan Proposal, the AHA for the 2009-2012 term was not to exceed three-fifths of the 2004-2024 FMP AHA by forest unit (16,924 ha) and allocations were to reflect the age classes from the 2004-2024 FMP. In the 2009-2012 CP total allocation does not surpass AHA by forest unit and planned harvest generally coincides to the AHA by age class although some substitution for younger wood occurred "in order to form operational blocks". The age class substitution was considered "minor in magnitude and short-term (one year's harvest)" and therefore would "not impact long-term forest sustainability". The auditors agree with this assessment and expect that this will be taken into consideration when the remaining harvest areas are selected.

Approximately one year of allocation was planned in the 2009-2012 CP – 5,367 ha (31.6% of the three year AHA). The remaining two years of allocations were expected to be amended to the plan as needed. It was noted that the one year of planned harvest favoured the younger age classes forecast for harvest. MNR noted that there was no intent to target younger wood.

The Contingency Plan Proposal indicated that up to six months of contingency harvest area was to be identified to be utilized should unforeseen circumstances cause some of the planned harvest area to be unavailable for harvest during the 2009-2012 period. The contingency area was to be selected based on the selection criteria listed in the Contingency Plan Proposal. The 2009-2012 CP correctly noted use of contingency area, confirmed the Contingency Plan Proposal direction and noted that 2,889 ha were selected as contingency area (almost exactly six months worth of allocation). Some required documentation is missing regarding accessibility and road planning for contingency areas. This text should be included in the next FMP.

The 2009-2012 CP notes that "disturbance frequency distribution by size class was a component of the strategic planning carried forward to this contingency plan, therefore maps and associated analyses were not redone for this plan". Also, "the analysis of the effects on landscape pattern will occur as part of the development of the 2012-2022 FMP". Table FMP-16 indicates the total number and size of planned clearcuts for the one year of planned operations as well as the ratio of <= 260 ha to >260 ha clearcuts. The ratio is expected to be about 80/20 for the Boreal Forest but only 46/54 is attained "in order to create large, even-aged patches of forest for future caribou and marten core habitat areas and to move towards the natural disturbance frequency by size class template for the Forest". It is also expected by the planning team that this ratio will improve when the remaining two years of allocations are selected.

Residual stand components were considered in the 2009-2012 CP through planning for leaving uncut insular and peninsular areas in planned clear cut areas, standing individual live and snag trees and downed woody material. This planning met requirements.

According to the 2009-2012 CP there had not been any significant changes to the land base since the 2004-2024 FMP was developed. However, as early as 2006 forest managers knew that 87,000 ha (12.5% of the Whiskey Jack Productive Forest) was infested with jack pine budworm. Insect Pest Management Plans covering several forests in the area were developed and implemented in 2006 and 2007 to battle the jack pine budworm (discussed further in the Contractual Obligations section).

Edited by Foxit Reader

For Evaluation Only.

Approximately 30,000 ha of the Whiskey Jack Forest was sprayed over those two years. Although there were allowances in the Insect Pest Management Plans to re-direct planned harvest in the outbreak area, MNR noted that this was not considered for the Whiskey Jack Forest. The auditors believe that, at the least, the fact that an outbreak had/was occurring on the Forest and that plans had been developed and implemented in 2006 and 2007 should have been discussed in the CP rather than classifying this event as non-significant.

The 2009-2012 CP outlined a thorough program to monitor compliance, exceptions, silviculture and roads. Planned levels of monitoring were appropriate. MNR prepared the Strategic Compliance Plan for the contingency plan and committed to implementing the compliance program due to the company surrendering the SFL. No level of inspections was included in the compliance plan (this is done in the annual compliance schedule) but compliance history, issues and focus was detailed as well as compliance objectives for the term. Compliance and monitoring are discussed further in the Monitoring section of this audit report.

There were two plans within the audit term that were available for review of amendments – the 2004-2005 Contingency Plan and the 2004-2024 FMP. There were no amendments to the 2009-2012 Contingency Plan within the audit term. The 2004-2005 CP had 17 administrative amendments and the 2004-2024 FMP had 16 amendments, all were administrative except for one minor amendment to modify an osprey AOC. Amendments were normally a result of updating the plan based on actual field conditions or for providing operational flexibility in a challenging market place. The amendment classifications were appropriate, the number of amendments was not large, and the issues for amendments were common ones.

The 2004-05 Annual Work Schedule (AWS) was also the 2004-2005 Contingency Plan for the Whiskey Jack Forest until the 2004-2024 FMP was approved and implemented in February 2005. According to the 2004-2005 AWS/Contingency Plan text "the Contingency Plan is in effect until the 2004-2024 FMP is approved and implemented. Upon implementation of the FMP, the Contingency Plan will expire. Following that the 2004-2005 Annual Work Schedule will come into effect until March 31, 2005". It is not clear from this text what effect moving from the 2004-2005 Contingency Plan to the 2004-05 AWS will have on forest operations included in the text/tables. This should be clear for public review.

The audit team found a lack of agreement between text and tables during its review of the AWSs. For example, the 2004-2005 Contingency Plan/AWS text noted 5,971 ha planned for harvest while tables indicated 6,866 ha. This may be due to revisions/amendments made to the document during the year but there are no version numbers or other identifier to indicate possible differences. There were also discrepancies and issues with other AWSs – the 2005-06 'current' version had highlighted changes throughout. The 2006-07 and 2007-08 AWS table and text values were not always in alignment. These variances may have been due to different document versions (i.e. the AWS text was usually in Microsoft Word or Adobe Acrobat format and the tables in Microsoft Excel) or are simply errors. Although there were fewer issues with the 2008-09 AWS it is suggested that a document control protocol be developed and implemented to improve the quality of hard copy and electronic versions of AWSs and other documents. These public documents should be accurate and complete.

AWSs during the term indicated more than one year's worth of allocations to "allow flexibility". The flexibility provided was very large in a few AWSs. For example; the 2005-06 AWS included 64% of the 2004-2009 allocation, which is over triple the average annual allotment. Reasonable rationale was provided for the large yearly allocations. Overall, there was good correlation between the AWSs and the 2004-2024 FMP. All components were completed and included required information.

Forest Operation Prescriptions (FOPs) for harvest, renewal, and maintenance (tending and protection) operations were consistent with the SGRs in the applicable FMPs and were prepared according to requirements in the FMPM and FIM, with one exception – the FOP revision process was not followed. Instead of verifying prescriptions in advance of operations, changes to prescriptions were made and

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

submitted annually to MNR. However, according to the 2009 FMPM, changes to silviculture prescriptions now need only to be maintained by the SFL holder, so no recommendation is made in the audit.

4.4 Plan Assessment and Implementation

Plan Assessment

The Forest was generally well described in the 2004-2024 FMP and reflected the geology, soils, and sites as well as depletions, accruals and FEC types viewed during the audit; however little analysis and discussion regarding the historic forest condition and related management implications was presented in the FMP and the available information was not incorporated into the selected management alternative.

While the forest description text in the 2009-2012 Contingency Plan was a marked improvement when compared to the predecessor, the strategic direction from the 2004-2024 FMP was brought forward to the 2009-2012 Contingency Plan, and therefore the Natural Benchmark (NB) was again not a reflection of the natural forest as described in the Contingency Plan. The recommendation for this finding is included in Recommendation 5 below.

A number of objectives in the 2004-2024 FMP and 2009-2012 Contingency Plan had targets based on the 'natural bounds of variation'. The 'bounds' were derived from +/- 20% of the highest and lowest points of the Natural Benchmark. The issue is that the benchmark starts at a current condition that had over-representation of mixed wood and jack pine stands and under-representation of spruce. In addition, the objective targets were not linked to the trend line of the NB. As a result, the target of staying within the natural bounds could be met even while the management strategy moves away from the Natural Benchmark. For example, the NB indicates a slow steady rise of jack pine into the future but the selected management strategy decreases slightly through time.

Recommendation 5: The Forest Manager must ensure that, if required, the Natural Benchmark (or equivalent) developed for the next FMP better reflects actual conditions and that, if required, targets/desired levels (or equivalent) for appropriate objectives in the next FMP include consideration for the Natural Benchmark trend line.

Areas of Concern

The field portion of the audit included field examination of a number of harvest blocks in which AOCs were established to protect known values. Included in the field sample were AOCs protecting lakes and streams as well as nesting sites of eagles, ospreys and herons, and moose aquatic feeding areas. A number of tourism AOCs were also viewed.

Examination of AOCs from the air and on the ground, as well as on supplemental aerial photography showed that AOC boundaries were maintained. AOC prescriptions afforded appropriate protection to the values and followed FMP and AWS direction.

Harvest

A sample of harvesting operations was audited in the field by truck and helicopter in September 2009. The sample included harvest operations for each of the contractors that worked on the Forest during the audit term, across all seasons and included full tree to roadside and some cut-to-length operations. Roadside operations included round wood processing and chipping. Salvage of blown down timber was also viewed.

Block boundaries followed FMP/AWS mapping and good cut block boundary control was viewed during the audit. According to compliance records, there were a few trespasses during the term but they were not large. Continued training and use of GPS devices is reducing this issue on the Forest.

For Evaluation Only.

Harvesting operations audited showed a high level of compliance, particularly in light of the poor market conditions during most of the audit term that resulted in downsizing and layoffs across the sector. There was one notable exception on Puzzle Lake Road where there was some site damage and utilization issues. These problems will likely be overcome through further training and monitoring. Given the fact that this was an isolated case, no recommendations for corrective action are required.

A number of harvest blocks were visited that were to include moose shelter. In several cases, moose shelter patches had been harvested and had not been left as required.

Recommendation 6: The Forest Manager must ensure that moose shelter patches are retained as specified in the FMP.

Site disturbance from rutting was identified as an issue in the previous IFA. This problem has been virtually eliminated on all sites examined during this audit. Fine textured soils are common on portions of the Forest. These soils are vulnerable to compaction and many sites showed evidence consistent with this type of damage (i.e. reduced regeneration of trees along machine routes). These sites cannot be operated upon during wet conditions or a non-frozen condition. In addition, approximately half of the harvest blocks observed by the audit team had operations that extended beyond one season. Many of these blocks were re-opened on several occasions. This practice can exacerbate site damage from compaction and creates compliance monitoring issues.

Recommendation 7: The Forest Manager must ensure that operators refine their work methods on fine textured soils to avoid operating during wet or non-frozen periods.

Silviculture

For the five-year term being audited, the audit team viewed a representative sample of each type of regeneration and site preparation operation conducted annually to assess the effectiveness of the silviculture prescriptions. Aerial photographs, maps, Annual Work Schedules, Annual Reports and Forest Operations Information Program (FOIP) information was used to aid in the audit of the renewal activities.

Operations viewed by the audit team included site preparation, seeding jack pine following site preparation, planting (with and without site preparation) and natural regeneration mainly on hardwood-leading/mixed wood and lowland sites. Slash management and the silviculture exception of full tree harvesting on very shallow soiled sites were also audited. It was evident at several sites that conifer establishment is being hampered by competition. Tending is discussed later in this section.

Renewal operations were consistent with locations in the FMP/AWS in most cases and silviculture mapping was generally well done. This included those areas reviewed in concert with the Specified Procedures Report.

Free-to-Grow (FTG) record updating completed during the audit term was not always accurate. This finding is based on some obvious issues noted during the FTG program review. For example, some areas dominated by jack pine with a small spruce component were recorded in the inventory as spruce stands with a small component of pine; the opposite was also found. Based on the sample audited, the quantity and significance of discrepancies found indicated a systematic data entry issue that needs to be corrected. The monitoring section contains a full account of the silviculture monitoring program including FTG assessments conducted during the audit term.

Recommendation 8: The Forest Manager must ensure that the inventory is reviewed and verified for accuracy with respect to Free to Grow records updated during the audit term.

For Evaluation Only.

Site preparation (trencher) was under-achieved during the audit term - about 7,800 ha of 15,922 ha planned was completed (~50%). The work was often too light and spacing was too wide between passes leading to reduced planting spots on many sites.

Recommendation 9: The Forest Manager must ensure that site preparation results in the production of planting spots of the quality and quantity appropriate to meet plan objectives.

The planting program during the audit term exceeded the planned program - 11,850 ha versus 6,278 ha (190%) but due to the under-achievement of site preparation, a large component (~50%) was direct plant (i.e. planted without site preparation).

A review of planting density from the Annual Reports indicates a pronounced reduction of seedlings per hectare during the audit term (average 2,000 seedlings/ha in 2004-05 decreasing to 1,334 seedlings/ha by 2008-09). Ingress was sparse on many of the sites viewed and was generally limited to jack pine on shallow soiled/rocky upland areas and black spruce on some lowland sites. Consequently, there will be a need for fill planting on many sites to meet plan objectives.

In spite of vegetative competition on many sites (discussed later), most black spruce stock that has thus far survived had excellent growth; however, it was noted that the stock selected for some very shallow or wet sites did not perform well. Alternative stock may be preferable on these sites. It was also observed that few white spruce, red pine or white pine were planted during the term. The plan target to enhance red and white pine on the Forest will not be met unless treatments include these species on appropriate sites.

Recommendation 10: The Forest Manager must ensure that planting of red and white pine occurs on appropriate sites.

It was noted that there was no plan objective/target to maintain on the Forest (other than red and white pine) the presence of less common tree species such as white spruce or black ash. This should be considered for the next FMP.

Many areas that were seeded were not well stocked and will require fill plant/re-seeding to meet plan objectives. Under-stocking of seeded areas is mainly a result of low germination due to light and wide site preparation.

Slash management during the audit term was variable. At the beginning of the audit term effort was made to pile and burn slash; however, the company did not conduct a slash management program from 2007 to 2009. If left untreated, this will effectively remove large areas of productive land from the land base, likely for decades.

Recommendation 11: MNR Kenora District must ensure that all blocks harvested during the audit term are reviewed for slash management and, where established regeneration will not be affected
a) slash be piled and burned or otherwise removed to allow regeneration of productive land, or
b) if natural regeneration of these areas is not expected, then treat the area to ensure regeneration.

Possible compaction of fine-textured soils, as previously discussed, may be the cause of large grassy or open patches observed on many of these sites. Poplar shoot blight is also an issue on a majority of the Forest; regenerating poplar trees are being delayed and damaged by this disease. As a result, the required 70% stocking may be difficult to achieve on some of these sites. Related model inputs may need to be revised in the next FMP to ensure consistency with field conditions.

Tending was an issue on the previous two audits and is considered the most important issue on the Forest in this audit. Little tending was completed during the audit term. Chemical tending was planned in the 2004-05 AWS and 2005-06 AWS however no program was carried out. The reason stated in the

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

associated ARs for cancellation of the planned spray program was "concerns about the use of herbicides from stakeholders on the forest". In subsequent AWSs no specific area for spraying was identified, although it remained an option, subject to discussions with First Nations and stakeholders, however, no spraying was conducted in the remaining years of the audit term.

Tending completed consisted solely of pre-commercial thinning of 1,370 ha of 2,900 ha planned (~47%), which was well done. No chemical, mechanical or manual plantation cleaning occurred even though 8,737 ha were planned. The lack of cleaning, particularly on areas planted and seeded, is considered by the audit team to be a crucial finding. Many sites viewed require some form of competition control to meet plan objectives. In the absence of a competition control program, the Desired Future Forest Condition described in the 2004-2024 FMP and the 2009-2012 CP will not be achieved. Site preparing, planting and seeding of areas without effective competition control is also viewed as a loss of value.

ACCC chose to suspend the vegetation control program in the final year of implementation of the 1999-2019 FMP while discussions were taking place with Grassy Narrows First Nation; a community that is generally against the use of herbicides. Because several artificial renewal sites on the Whiskey Jack Forest were in need of tending at the time to meet plan objectives, the audit team for the 1999-2004 IFA recommended that ACCC implement an approved vegetation control program; however, no vegetation control program occurred during the 2004-09 term. Document review suggests that the company considered replacing aerial spray with ground spray for several candidate vegetation management sites but no ground spray was conducted. Documents also showed that the company chose not to spray during implementation of the 2004-2024 FMP in order to avoid the anticipated political backlash from Grassy Narrows First Nation.

Some older FTG areas viewed during the audit were vigorous and composed of almost pure conifer. These areas demonstrate the capacity of the Forest under an effective competition control regime and are the model for the Desired Future Forest Condition as described in the FMPs. According to silviculture monitoring completed during the audit term, about 22,000 ha of older disturbed area requires competition control in order to meet regeneration standards. The combined effort of tending requisite areas renewed during the audit term and these older stands will be considerable.

Recommendation 12: MNR Kenora District must ensure that:
a) a review is conducted of all areas planted and seeded during the audit term and that fill planting or re-seeding occurs as necessary to support the achievement of FMP objectives,
b) a review of all sites harvested during the audit term that are forecast to become conifer-leading forest units is conducted, and that tending occurs where necessary so that plan objectives can be met.

Even though there were numerous sites that required fill planting or other re-treatments to ensure plan objectives could be met, few remedial treatments occurred during the audit term (51 ha of re-planting). The recommendations associated with this section should lead to the re-treatment of a significant number of blocks.

No tree improvement activities were conducted during the audit term. However, managers of the Whiskey Jack Forest were an active participating member of the Superior Woods Tree Improvement Association. Any activities carried out on the Association's orchards are the result of decisions made by the Association.

At the time of the audit two of three jack pine seed lots stored will not meet the annual seed supply requirements noted in the 2009-2012 Contingency Plan. There should be at least a few years worth of seed stored for each species/seed zone combination on the Forest.

Recommendation 13: The Forest Manager must ensure that seed collection and storage meet the needs of the renewal program.

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

Underachievement of many planned renewal activities during the term was partially due to the reduced harvest level during the term but was largely due to selecting new less intensive treatments for many stands (for example, many areas planned for 'Intensive' treatments – site preparation, planting and tending – were simply direct planted – a 'Basic' treatment). Based on poor field results (as discussed previously in this audit report), it appears that reducing silviculture costs, rather than adjusting operations according to actual field conditions, was the main reason for changing from preferred to alternate prescriptions in many cases. The cycle of silviculture cost reduction started with selecting less intensive/costly options to implement in the field, building a surplus in the Forest Renewal Trust Fund (FRTF) and then using the surplus as evidence in the request to reduce contribution rates during the term.

During the audit term the company requested contribution rate decreases for spruce, pine and fir. In spite of MNR's own information that indicated problems with the renewal program, MNR approved on two occasions during the audit term the company's request for reductions in the FRT fund contribution rate for spruce, pine and fir. FRTF funding is also discussed in the Contractual Obligations section of this report.

Plan objectives and the desired future forest condition on many sites will not be achieved with the renewal options chosen, particularly in light of the operational issues noted. Adequate renewal funding is needed to ensure that appropriate silviculture is completed and plan objectives can be met. Additional funding will also be needed to fulfill actions for several recommendations in this audit report.

Recommendation 14: MNR Kenora District must review the Forest Renewal Trust Fund rates particularly for spruce/pine/fir and assign rates appropriate for meeting plan objectives.

It is obvious from the findings above that there was considerable erosion of the silviculture program on the Whiskey Jack Forest over the past several years, particularly later in the 2004-2009 term:

- vegetation control was not conducted,
- site preparation program was reduced and not closely monitored for effectiveness,
- the planting program focused on direct planting with little control of density,
- planting density decreased significantly,
- seeding was not always effective,
- adequate seed was not maintained for some seed zones, and
- slash management decreased significantly.

Appropriate actions to address the recommendations provided are needed to ensure plan objectives are met and to work towards a desirable future forest condition. This work should not be delayed and will come at significant effort and cost. Otherwise, a steady erosion of a conifer-dominated forest condition to one with significantly more mixed woods at reduced stocking can be expected with the continuance of this silviculture program.

Access

During the field portion of the audit, several harvest blocks were viewed where road rehabilitation should have occurred. Road rehabilitation can provide a means to effectively return land to the productive land base as well as eliminate unnecessary and disproportionate loss of productive land where excessive road building has occurred. A road rehabilitation strategy would assist in conducting the work efficiently.

Recommendation 15: The Forest Manager must develop a road rehabilitation strategy for the next FMP to ensure that unwarranted roads are rehabilitated and returned to the productive forest landbase.

Numerous water crossings and drainages were examined during the audit with marked improvements compared to that described in the past IFA. Water crossing installations that were performed in winter

Edited by Foxit Reader
Copyright(C) by Foxit Software Company 2005-2007
For Evaluation Only.

were found to be inadequate or failing. Erosion of winter road surfaces and unstable slopes were found at several water crossings. Monitoring is required to properly address the potential failure of water crossings that are installed during the winter. A monitoring program should be developed and incorporated into the FMP that includes monitoring crossings the spring following installation.

Recommendation 16: The Forest Manager must develop a monitoring program to ensure that all water crossings installed during the winter are inspected immediately following the first spring thaw after their installation, and incorporate the monitoring strategy into the FMP.

Aggregate pits were generally found to be in good condition, the result of the cooperative effort between ACCC and MNR to monitor and rehabilitate pits where necessary. One aggregate pit was found to have been operated since the rehabilitation effort was completed, without proper rehabilitation afterwards as required by the Aggregate Resources Provincial Standards. This condition may present a public safety hazard if left unaddressed.

Recommendation 17: The Forest Manager must ensure that the interests of public safety are paramount for establishing pit rehabilitation requirements for all pits at all times.

4.5 System Support

The Human Resources component of IFAPP Principle 5 is deemed to be met for both the company and MNR, according to the IFAPP, since the Whiskey Jack Forest was certified under the CAN/CSA Z809-02 certification standard for most of the audit term.

Information necessary for planning, implementation and reporting on forest management was generally thorough and well maintained. Much documentation is managed electronically, including maps and the associated attribute information. Paper records at MNR's Kenora District office were well maintained, typically in binder form and information was readily retrievable. Virtually all of the information associated with managing the Whiskey Jack Forest had been transferred from ACCC to MNR at the time of the audit, as part of the SFL surrender process.

4.6 Monitoring

Silviculture

The silviculture monitoring program was assessed through interviewing company and MNR staff, examining actual field data, reviewing all Annual Reports, and through viewing a sample of sites deemed FTG during the audit term. MNR records of silviculture effectiveness monitoring were also reviewed.

The company invested significant resources in completing a very large silviculture monitoring program during the audit term. The regular FTG program (18,000 ha) was completed by company staff mainly by helicopter where appropriate but also through ground plots when more intensive assessment was required. The barren and scattered/backlog update project (93,000 ha) was completed by a contracted firm.

The audit included a ten percent sample, mainly by helicopter, of the regular and backlog update assessment areas. It was found in many of the backlog update areas deemed FTG that the hardwood composition was under-represented and that age and height was under-estimated in the inventory. The extent of the discrepancies between the original survey data and the status of the surveyed areas as observed by the audit tam could only be attributed to inaccurate calls during the original survey. Other than age, similar issues were found with the regular FTG program while stocking was also sometimes over-estimated and broad stratification was also noted.

It is estimated that the barren and scattered survey cost over one-half million dollars to complete (~$6/ha) but timing of the assessment and the methodology required for updating the inventory reduced the accuracy of the product. It is important that future surveys are completed in a manner that allows for accurate hardwood estimation and that the inventory updating process maintains the accuracy of field information.

In the Plan Assessment and Implementation section of the audit report a recommendation is made to review FTG records updated during the audit term and ensure the data is accurate. The following recommendation builds on that by ensuring that the original field data is fully incorporated.

Recommendation 18: MNR Kenora District must ensure that a review of the original field data of the barren and scattered survey occurs and that the inventory is appropriately updated with this information.

The level of silviculture assessment completed by the company during the audit term was appropriate and consistent with past operations and natural disturbances and was sufficient for reporting on the effectiveness of forest operations in meeting plan objectives. However, as discussed, apparent data entry errors were found and there were notable issues with some calls. The audit team believes that, following the update and verification, as recommended by this audit, the inventory of the barren and scattered areas will suffice for strategic-level planning until the next full inventory is completed, the tentative delivery schedule for the next forest inventory being 2015.

Since 2006, MNR has conducted an annual Silviculture Effectiveness Monitoring (SEM) Program. The program has focused on verifying FTG calls and checking effectiveness of silviculture treatments such as planting and site preparation. Through the SEM program it was determined that SGR standards were rarely met on FTG areas mainly due to under-stocking, particularly of desired conifer species, versus the regeneration standards. It was also found that direct planting did not result in adequate stocking and site preparation was too wide to allow full stocking of sites. SEM results confirm audit findings related to under-estimation of hardwood and over-estimation of stocking in FTG areas and concerns with light and wide spacing of site prepared areas and wide spacing/missed areas in direct planted areas.

Recommendations provided in the Plan Assessment and Implementation section were made to improve the site preparation, planting, seeding and tending programs. The audit team expects that actions taken for these recommendations will include a thorough review of silviculture operations that occurred during the audit term and significant effort in re-treating and/or tending of several blocks. Completion of this work will be vital, particularly to the future SFL holder. As a result, extra care should be taken to fully and accurately monitor and record these efforts.

Compliance

MNR developed annual compliance operating plans (ACOPs) during the audit term that described actual compliance targets by forest operation. Planned compliance monitoring rates in the ACOPs varied during the term. The 2006-07 ACOP notes that the harvest target monitoring rate of 25% has never been achieved so the target was dropped to 10% and modest renewal targets were reinstated. Similar rates were maintained for the remaining two years of the audit term. MNR staff noted that the changes to targets during the audit term were a result of achieving a balance between targets suggested by the Forestry Forum and resources to complete the actual tasks. Based on audit results and other MNR initiatives during the audit term such as silviculture effectiveness monitoring, the targets set in the more recent ACOPs are appropriate and adjustments can be made as necessary.

Viewing supplemental aerial photography (SAP) is an efficient way to augment the compliance monitoring program. Road layout, boundary control, residual standing individual and patches of trees and slash/chipper debris management are some of the operations that can be readily observed on SAPs. MNR staff noted that SAPs were requested from the company during the term but that the company was

unwilling to provide them. Source data, including SAPs, is required to be provided by SFL holders to MNR (FIM 2007); this is normally not an issue.

According to the 2008-09 Annual Report MNR certified inspectors completed 109 inspections during the audit term. Although the ACOP targets were not met in some years during the audit, this is an appropriate amount of inspections by MNR, particularly in light of the reduced operations later in the term. Reports reviewed were detailed and many included useful digital images.

The Strategic Compliance Plan for the 2004-2024 FMP was completed by the company and met requirements. Due to the imminent surrender of the SFL by ACCC, MNR authored the Strategic Compliance Plan for the 2009-2012 Contingency Plan. This document was also well written and met requirements and indicated that MNR will assume responsibility for compliance monitoring in the absence of a new forest management group. Each of the Annual Work Schedule submissions during the audit term included an Annual Compliance Schedule. The Annual Compliance Schedules described the planned compliance monitoring program for the year, culminating in a table that summarized all planned operations by expected start season.

During the audit term ACCC maintained its compliance oversight role by developing the required compliance documents, inspecting operations and providing education/training to staff and contractors/overlapping licence holders. According to the Strategic Compliance Plan in the 2004-2024 FMP, overlapping licensees were responsible for construction and maintenance of all roads on their operations and the identification of all AOCs and harvest block boundaries. Therefore Overlapping Licensees were only required to be compliant, not complete inspections, etc. MNR confirmed that this arrangement occurred during the audit term.

MNR had little involvement with the company's internal Environmental Management System, training and education program but believe that a good program was in place, based on the relatively good compliance record of the company; the auditors concur. MNR did assist the company with Forest Operations Inspection Program training during the audit term.

According to the Year 10 Annual Report, the company completed 413 inspections during the audit term. This level was appropriate for the reduced operations that occurred during the term. Company reports reviewed were generally good and, according to MNR and audit review, content improvements were made during the term. MNR noted that compliance report submissions by MNR and ACCC often did not meet the required timelines earlier in the audit term but that both parties had improved in this respect.

Water crossing installations, roads issues, small trespasses and operating near unmapped streams were the common non-compliances found during the audit term. Overall, the company found 14 non-compliances during the term (a 96.6% compliance rate based on 413 inspections) and MNR found 20 (an 81.7% compliance rate based on 109 inspections). It is common for discrepancies in reported compliance rates between forest management firms and MNR but the 15% difference on the Whiskey Jack Forest during the audit term suggests inconsistent compliance interpretation. In addition, differing opinion regarding compliance was highlighted in two annual reports during the term - "The company does not agree with all of the MNR's findings…It was requested these reports be re-opened and their compliance status be changed to in compliance". MNR noted that the compliance status of these issues was reviewed and found to be correct so no changes were made to compliance reports as a result of the company's request.

As discussed, ACCC has now surrendered the SFL to MNR and a new entity will one day manage the Forest. Forging a cooperative relationship should be a priority of MNR and the new managers.

Annual Reports

Annual reporting during the audit term was fairly well done. The ARs were generally well written, numbers in text and tables were typically in agreement and 'to date' summaries were usually correct; however there were some concerns noted regarding the accuracy of some information. Based on the field audit, the activities conducted during the term, including monitoring and assessment, were summarized in the ARs.

In addition to the numeric errors, potential implications of deviations from plan values were rarely discussed or were discussed with little detail. For example, deviations between planned and actual levels were provided for all activities and reasoning was often provided for achievement rates but discussion of how this affected or will affect plan objectives did not occur. Also absent in the ARs was discussion regarding the implications of silviculture success (a very important measure of the ability to successfully apply renewal prescriptions) on the achievement of plan objectives.

As discussed previously, the lack of tending during this audit term raises significant concerns regarding objective achievement and future forest condition. However, there is limited discussion in the ARs regarding the possible affects due to lack of a tending program. One AR statement - "Prompt renewal activities with the use of superior growing stock are assisting to offset the absence of chemical tending" - actually raises more questions than are answered.

ARs are required to discuss monitoring of exceptions to forest management guides, reasons for non-compliances, and the effectiveness of road use management strategies, among other things; however, discussion on these required topics was limited in the ARs.

ARs should be a clear and accurate account of annual forest operations but are often inadequately completed. ARs normally meet the basic accounting/summary of operations but miss the deeper discussions required of the FMPM. Moving forward, this should be considered during development of ARs.

Recommendation 19: The Forest Manager must ensure that:
a) all information in the Annual Report is confirmed for accuracy prior to finalization,
b) future Annual Reports contain all required discussions including progress towards achievement of plan objectives, potential implications of operations on future operations and effectiveness of road use management strategies.

4.7 Achievement of Management Objectives and Sustainability

Year 10 Annual Report

The Year 10 AR (2008-09 AR) was a fairly accurate and complete compilation of activities that occurred during the 2004-09 term but some errors were noted when comparing the Year 10 AR values to a summary of the ARs. Besides relatively minor accuracy issues, the Year 10 AR, as was the case for the regular ARs, lacked most of the deeper analyses and discussions that are required. Bearing in mind the numerous and considerable issues noted in the ARs and witnessed during the audit, the Year 10 AR should have been a substantial document that 'set the stage' for the next FMP. Rather, the tendency in the Year 10 AR was to provide cursory explanations for many important trends, delay required analyses and make poor excuses, such as the 2009-2012 Contingency Plan's utilization of the 2004-2024 FMP strategic direction, for not completing required work. In summary, the level of analysis and discussion in the Year 10 AR is deemed to be sub-par and inadequate. This must be rectified so that gains in knowledge made over the audit term are available for use during the development of the next full FMP for the Whiskey Jack or amalgamated Forest, which was already in progress in the fall of 2009 during the audit.

Recommendation 20: MNR Kenora District must ensure that the 2008-09 Year 10 AR is revised to include the following:

a) analysis/discussion of changes that may affect future levels, effectiveness and expenditures of renewal and tending operations,
b) analysis/discussion of effectiveness of silvicultural treatment packages that are exceptions to the forest management guides,
c) review/discussion of needed modifications or refinements to modeling assumptions,
d) a summary of progress on implementation of the 1999-2004 IFA Action Plan,
e) an update of the inventory and running of SFMM at plan end (2009) to determine objective achievement,
f) an update of the 2004-2024 FMP social and economic description, and
g) based on the determination of sustainability and the social and economic review, develop recommendations for the next FMP.

Achievement of Management Objectives

Ten of the 16 objectives set in the 2004-2024 FMP were achieved. The silviculture objective was not met since the program being applied does not support the forecast in the Selected Management Alternative. In addition, the audit team does not believe that the objectives for forest structure or for maintenance of habitat for selected wildlife species or marten will be met in practice due to the disconnect between the future forest condition as represented in modelling compared to the actual forest resulting from the silviculture program being applied on the ground. The silviculture program will lead to a forest with more hardwood and less conifer.

Harvest was well below target levels due to the permanent closure of the Kenora paper mill and the protracted idling of Kenora Forest Products. This shortfall was also related to AbitibiBowater no longer sourcing wood from the Whiskey Jack Forest for its mill in Fort Frances. Objectives for sustained wood supply and forest resource use commercial (i.e. Weyerhaeuser) will not be met.

A significant shortfall in harvest area was experienced over all three terms reported in the Trend Analysis, with a cumulative total shortfall of 45,000 ha by 2009. This was offset to some extent by natural depletions due to blowdown and jack pine budworm, although the nature of the forest resulting from these events is different than the forest that results from clearcut harvesting and associated silviculture.

While total renewal area significantly exceeded harvest area over the past three terms, more recent forest composition, pattern and structure targets may not be met due to low harvest exacerbated principally by a lack of tending. This is illustrated in the Trend Analysis data which shows a 30% increase in poplar working group and a 46% decline in spruce working group over the last 15 years. There is also concern with meeting the soil quality objective on fine textured sites due to multiple entries, although rutting and other forms of site damage were observed to be minimal. Discussion on the achievement of the full set of management objectives is contained in Appendix 2. The objectives for the 2004-2024 FMP were carried forward into the Contingency Plan; therefore certain objectives will similarly not be met if current trends continue.

Trend Analysis Report

ACCC prepared a draft Comparison and Trend Analysis Report (TAR) covering fifteen years of operations (1994-2009) on the Whiskey Jack Forest. The audit team reviewed the draft according to the procedure in the IFAPP and identified the need for changes, following which a final TAR was resubmitted by ACCC. The TAR included as Appendix 7 to the audit report is the correct and complete report. The period covered by the analysis encompasses four separate FMPs: one each for the Pakwash Forest and Patricia Forest and two for the amalgamated Pakwash and Patricia Forests (i.e. the Whiskey Jack Forest). During this time frame there was an 8% reduction in the production forest landbase due principally to withdrawals for parks and protected areas. There was a notable shift in the composition of the tree cover with a large increase in jack pine and poplar working groups and correspondingly large decrease in

spruce working group. Harvest area averaged 53% of planned resulting in a cumulative total of approximately 45,000 ha of available harvest area remaining uncut by the end of the fifteen years. Utilization of the available poplar fibre resource increased significantly with the opening of the Weyerhaeuser strand lumber mill in Kenora whereas the available jack pine and spruce were significantly underutilized during the last five years due to recent mill closures and changes in fibre sourcing policies, as previously mentioned.

Large natural disturbance events (principally jack pine budworm infestation) resulted in a reported depletion of some 218,000 ha or 27% of the forested landbase, approximately 90% having occurred in the 2004-2009 FMP period. Total renewal area significantly exceeded total harvest area due to the overall shortfall in actual versus planned harvest area. There was a recent shift to a greater reliance on natural regeneration and a very steep decline in chemical tending, with resulting issues as previously discussed. Some 87% of the area harvested during the five years from 1994-1999 were declared FTG with most of the balance expected to meet the minimum regeneration standards in the near future. The reader should understand that areas meeting the minimum regeneration standards are not necessarily regenerating to the planned forest unit. For example, the Year 10 AR for the 2004-2009 period reports approximately 76% of the area declared FTG was regenerating to the planned forest unit.

Forest Sustainability

Forest sustainability (i.e. achieving plan objectives and the long term management direction set for the forest in the FMP) was not well-supported by the silviculture program. Corrective measures will need to be taken at both the plan level and at the operations level to reset the course towards what is thought to be the historic condition of a spruce dominated forest condition if that is the intent, or the plan adjusted to reflect the fact that a higher component of hardwood can be expected with continuation of the current silviculture program.

To a great extent, management of the Forest was significantly complicated by external social and economic factors. The protest by GNFN over forestry practices, including herbicide spraying, was a key factor influencing decisions not to spray herbicide on the Forest. Some 25,000 m^3 of wood was already stranded on the Forest as a result of an ongoing road blockade by GNFN. As the downturn in the forest industry took hold, harvesting on the Forest also began to decline. As a consequence, the balance in the Forest Renewal Trust fund account declined and forest managers began to rely more heavily on lower cost renewal treatment approaches.

Specific planning and operational issues associated with the silviculture program that underlie the problem are summarized below.

- The natural benchmark does not reflect plan intentions to develop a natural forest composition
- The selected management alternative moves the forest further from the natural benchmark
- The planned silviculture program does not meet the selected management alternative with respect to treatment intensities
- Silviculture inputs exceed the silvicultural ground rule standards in some cases
- Actual silviculture implemented is not meeting silvicultural ground rules
  - Stocking below target
  - Conifer composition below target
  - Loss of infrequent species (i.e. white spruce, red pine, white pine)
- Under-estimates of hardwood composition during free-to-grow surveys delays full detection of forest change until the next forest resource inventory is completed

Combined, these factors have led to a steady erosion of a conifer-dominated forest condition to one with significantly more mixed woods at reduced stocking. Forest sustainability, as assessed through the Independent Forest Audit Process and Protocol will not be achieved unless corrective measures are immediately taken.

4.8 Contractual Obligations

Appendix 3 summarizes the individual conditions arising from the SFL and provides the audit team's assessment of the extent to which each licence condition was met. Most conditions were met or partially met. Conditions not met were associated with maintenance of the Forestry Futures Trust minimum balance, the achievement of silviculture standards, and the timely completion and submission of IFA action plans and status reports.

Recommendation 21: The MNR Kenora District Manager and the Forest Manager must ensure that the audit action plan and status report comply with all IFAPP submission requirements.

As part of the review of contractual obligations, the audit team is required to assess the effectiveness of actions developed by the auditees to address the recommendations arising from the previous IFA. It was apparent from documentation, interviews and field observations that work had been undertaken on the 2004 IFA action plan and, according to the latest draft of the action plan available during the audit, virtually all of the audit recommendations were actioned. The audit team reviewed these actions and concluded that most audit recommendations were appropriately dealt with. However, the audit team disagreed with the status of "complete" for Recommendation 8 (silviculture strategies), Recommendation 10 (site disturbance), and Recommendation 11 (vegetation control program), as reported in the draft action plan, because the actions or their implementation have not adequately addressed the original issue. The audit team's concerns are captured in the associated discussion and recommendations contained in this audit report.

A final audit action plan, dated March 2010, was provided to the audit team. The deadline date for completion of actions associated with Recommendation 11 is now "ongoing". This change does not alter the audit team's view that the original concern identified in the 2004 IFA has not been adequately addressed.

Errors in text and tables and a lack of adequate discussion of issues and trends were found in the Annual Reports. The audit team does not believe the low cost approach to the silviculture program was always a wise or effective use of money from the Renewal Trust Fund, as evidenced by the often poor regeneration results on the ground compared to the expectations set out in the FMP.

The SFL holder worked for more than a year to secure a surrender agreement. Some of the delays were related to assessing liability for silviculture. The surrender agreement was signed outside of the audit period. However, the process behind securing the surrender agreement is material to the audit under the principle of contractual obligations.

The audit team believes that the process took longer than it should have. The issue of silviculture liability should not have been a stumbling block. The records should be up to date and MNR should move quickly to ensure the harvest and renewal programs proceed under a direct delivery model, a forest management contract or a new licence. Funds to complete forest renewal should be sufficient if the minimum balance has been maintained. Since more SFLs may be surrendered in the future, corporate MNR should undertake measures to allow for expedient surrenders of licences and interim measures to deliver the forest management program until such time as a new SFL is issued.

4.9 Conclusions and Licence Extension Recommendation

The audit team concluded that, with the following critical exception noted below, management of the Whiskey Jack Forest was generally in compliance with the legislation, regulations and policies that were in effect during the term covered by the audit, and MNR met its legal obligations. Forest sustainability, as assessed through the Independent Forest Audit Process and Protocol, will not be achieved unless corrective measures are immediately taken to address the issues that silviculture practices, including a lack of tending of artificially regenerated areas, are leading to reduced stocking of conifer and an

increased component of hardwood on the Forest. This trend does not support the management intention of maintaining a conifer dominated forest, as set out in the 2004-2024 Whiskey Jack Forest FMP.

- Recommendation 3 of this audit must be satisfied to bring the Whiskey Jack Forest into general compliance.

ACCC has surrendered the SFL for the Whiskey Jack Forest to the Crown; therefore the audit team makes no recommendation on licence extension.

Appendix 1 - Recommendations

Independent Forest Audit – Record of Finding **Recommendation 1**
Principle: 2. Public Consultation and Aboriginal Involvement **Criterion:** 2.1 Local Citizens Committee establishment and Terms of Reference **Procedure:** 2.1.1.1 Review the terms of reference and LCC minutes, compared to the applicable FMPM requirements.
Background Information and Summary of Evidence: The current Terms of Reference for the Kenora LCC and the Red Lake LCC do not contain a protocol describing the presence of or functioning of the two LCCs on the Whiskey Jack Forest.
Discussion: The 2004 FMPM Sections 3.2.3 and 3.2.4 requires that the LCC terms of reference contain a protocol which describes how multiple committees on a forest will function. There are two LCCs with responsibilities on the Whiskey Jack Forest (Kenora LCC and Red Lake LCC).
Conclusion: The Terms of Reference for both the Kenora LCC and Red Lake LCC do not meet the requirement of the FMPM with respect to a protocol for multiple committees.
Recommendation 1: MNR Kenora District and MNR Red Lake District must ensure that the LCC Terms of Reference for the Kenora and Red Lake LCCs meet the content requirements of the FMPM regarding a protocol for the functioning of multiple LCCs.

Independent Forest Audit – Record of Finding
Recommendation 2

Principle: 3. Forest Management Planning

Criterion: 3.5.4 FMP silviculture ground rules

Procedure: 3.5.4.1 Assess whether treatments for harvest, renewal and tending activities and regeneration standards appropriately reflect the selected management alternative/management strategy.

Background Information and Summary of Evidence: There were 45 Silviculture Ground Rules (SGRs) developed for the 2004-2024 FMP, which followed the requirements of the 1996 FMPM. These exact SGRs were used in the 2009-2012 Contingency Plan as stipulated by the approved Contingency Plan proposal. The SGRs are a relatively good representation of what is on the Forest but significant issues were found regarding specific components of some SGRs:

- Over-estimation of expected amounts of future conifer in some extensive SGRs, e.g. Mixed-E = 50%, PRW-E = 80%, SPDom-E = 80%.
- Acceptable species lists sometimes exclude important species such as red and white pine and white spruce.
- Some acceptable species lists include values that do not meet the intended future forest condition, e.g. PjDom-E has Pj>=50% when PjDom forest unit requires Pj>=60%.
- Unrealistic future forest condition in some cases, e.g. PjDom-SpDom with future forest condition that contains only 10% Pj.
- No allowance for cleaning treatments in PjDom-B or SPDom-B. If these SGRS are to have no more than 10% hardwood species at maturity some form of cleaning would be required on most sites.

Other, less significant issues found with the SGRs are also summarizedt to aid in the development of the next SGRs:

- Use of shelter cones is described for jack pine and black spruce seeding in some SGRs. This technique has not been used on the Forest in several years.
- Regeneration standards should be reviewed. SpLow-E has 60 cm height for black spruce at 15 years – this is extremely slow growth. Minimum average height is given for all species in some SGRs. This should be identified by species or, at the least, by conifer and hardwood.
- A few SGRs had both scarification and mechanical site preparation – this should not occur.

Discussion: Over-estimation of expected future conifer and under-estimate hardwood in affected SGRs can negatively impact future forest condition if not corrected. Predicting unrealistic future forest conditions and limiting treatment options could also have long term implications.

Regeneration and silviculture survey information available for the Forest corroborates most of the silviculture planning and implementation findings presented in this audit report. To date, the survey information has not been fully utilized when developing forest management plans.

Conclusion: Silviculture survey information must be analyzed and used by the planning team when developing the silviculture program for the next FMP. This will ensure the development of a management alternative that can meet plan objectives and develop a desirable future forest condition.

The recommendation below has been purposely expanded beyond the SGRs to include the entire silviculture program because it was found that several components of silviculture planning are in need of revision based on available information. Other silviculture planning issues are discussed elsewhere in this report.

Recommendation 2: The Forest Manager must ensure that available survey information (regeneration surveys, Free-to-Grow, silviculture effectiveness monitoring, etc.) is used in the development of the silviculture program in the next FMP.

Independent Forest Audit – Record of Finding
Recommendation 3

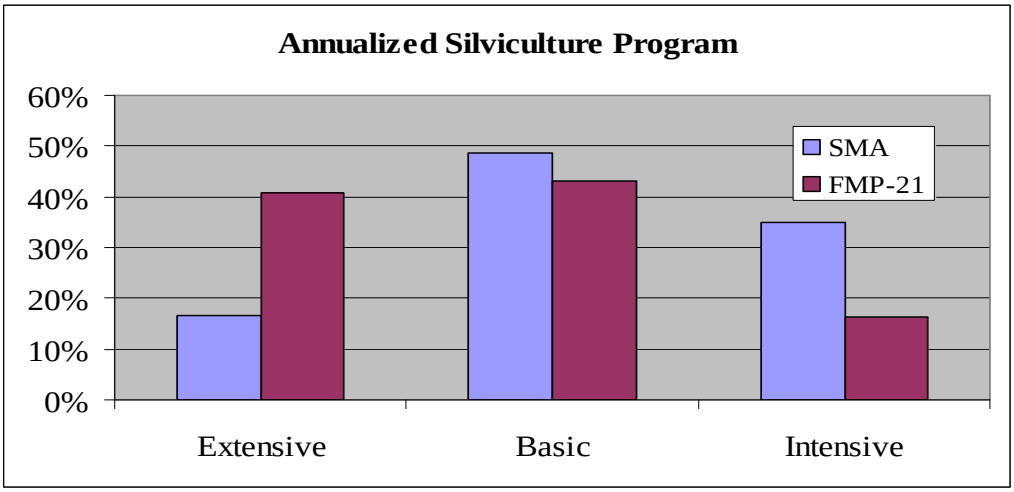
Principle: 3. Forest Management Planning

Criterion: 3.5.7 FMP renewal, tending, protection and renewal support

Procedure: 3.5.7.1 Assess planned implementation of the selected management alternative/management strategy.

Background Information and Summary of Evidence: The work to associate strategic to operational silviculture and the required discussion was deficient in the 1999-2004 Whiskey Jack Forest FMP and a recommendation was provided in the 1999-2004 IFA to remedy this (#8). Unfortunately, the 1999-2004 IFA recommendations were not available for the development of the 2004-2024 FMP and the Contingency Plan subsequently developed for the 2009-2012 term used the strategic direction from the 2004-2024 FMP, so actions on this recommendation have not yet occurred. This is evident because similar, if not greater, discrepancies with regards to the modeled and planned silviculture program are found in the 2004-2024 FMP and the 2009-2012 Contingency Plan; these are summarized below.

The figure below indicates considerable differences between the annualized modeled silviculture program by intensity (selected management alternative = SMA) and the planned program (FMP-21 from the 2009-2012 Contingency Plan).



Comparison of Modeled and Planned Silviculture Program by Intensity.

Table FMP-16 summarizes forest unit transitions expected to occur on the planned harvest area when the modeled silviculture program is followed. This table is limited to activities or changes predicted for the plan term (five years) but trends can be compared to the SMA to ensure consistency. Table FMP-16 in the 2004-2024 FMP (and the 2009-2012 Contingency Plan, which uses the strategic direction from the 2004-2024 FMP), indicates an increase in Mixed, PRW and PoDom forest units and a decrease of all the other forest units. These trends are similar to the SMA in the plans, but the magnitude of change is significantly different. In the five years of transition shown in Table FMP-16, the Mixed forest unit is to increase by 23.5% and SpDom is to decrease by 6%.

Another discrepancy found with regards to silviculture was between stocking rates in yield curves and stocking rates in Silviculture Ground Rules (SGRs). Stocking in yield curves was found to exceed target stocking in all SGRs. For example, PjDom-I yield curve has 100% stocking whereas the PjDom-I SGR only requires >=90%.

Planning for tending (release from vegetative competition) was also an issue in the 2004-2024 FMP and 2009-2012 Contingency Plan. Although there is no specific model input for tending, yield curves (predicted species composition, stocking and volumes), forest unit transitions and silviculture costing are developed based on the assumption of removing competing vegetation on most areas treated by planting or seeding (e.g. Intensive and Basic treatments). Therefore, it is usual to plan for competition control on all areas planned for Intensive

treatments and a large portion of those planned as Basic.

In the 2004-2024 FMP about 63% of silviculture treatment area was planned for planting and seeding (generally correlates to Intensive and Basic treatment intensities respectively). Of this area, less than half (~47%) was planned for tending. In the 2009-2012 Contingency Plan the proportion of artificial treatments planned decreased to ~59% of which just over one-quarter (~27%) was planned to be tended.

Discussion: Silviculture in a forest management plan may be broadly separated into the modeled and planned programs.

- The modeled or 'strategic' silviculture program links expected silviculture treatments and associated average yield curves by intensity. The strategic silviculture program is developed to meet related plan objectives and ultimately derive preferred future forest conditions – it is usually desired to move towards a historic/natural forest condition, normally defined in northern Ontario as one dominated by pure or mixed conifer stands.
- The planned or 'operational' silviculture program focuses on actual silviculture treatments by area based on those areas not yet treated or requiring re-treatment from the current/previous plan(s) and those planned for treatment in the upcoming plan term.

Although the modeled and planned silviculture programs are somewhat different, the two should be solidly linked to allow fulfillment of associated plan objectives through plan implementation. Furthermore, the connection between strategic and operational should be clearly discussed in forest management plans to provide confirmation that what is planned in the FMP can meet plan objectives and, in time, the preferred future forest condition.

To meet plan objectives, the SMA calls for a significantly larger proportion of intensive and basic treatments when compared to the planned program (Figure above). Exact correlation between these values is not expected but solid association is. No discussion is provided in the FMP for this discrepancy. Also, the very large percent changes by forest unit over short periods shown in Table FMP-16 are not consistent with the SMA and this is not discussed in the text of the FMP.

Over a large area, the reduction of volume based on 10% less stocking in SGRs versus the yield curves would be considerable. Furthermore, survey results indicate that only a small portion of Intensive treatments actually meet the 90% stocking requirement; the need for better inclusion of survey data is included with the SGR discussion with the previous recommendation.

The decreasing reliance on artificial treatments and tending is not in alignment with the selected management alternative, is not supported by results of actual treatments on the Forest and will not lead to objective achievement or producing the desired future forest condition. The need for tending is discussed in several other sections in this audit.

Conclusion: As noted earlier, the 1999-2004 IFA included a recommendation focused on improving silviculture planning but actions for this recommendation have not yet occurred due to timing of FMP development/need for a Contingency Plan. Several issues were also found regarding silviculture planning in the 2004-2024 and 2009-2012 FMPs. To ensure this important work occurs in the next FMP, a recommendation similar to the one in the 1999-2004 IFA is included in this audit.

The next FMP will be a significant improvement over its predecessors with the proper incorporation of field survey data (based on the previous recommendation) and through developing and detailing clear connections between strategic and operational silviculture (as a result of the recommendation below).

Recommendation 3: The Forest Manager must ensure that:

a) the Silviculture Ground Rules, silviculture exceptions, planned renewal program and actual silvicultural intentions of the next forest management plan support the long term management direction and related silvicultural strategies,
b) the connection between strategic and operational silviculture is clearly discussed in the text of the next plan, and
c) the operational renewal program aligns with the planned renewal program and supports the long term management direction.

Independent Forest Audit – Record of Finding
Recommendation 4

Principle: 3. Forest Management Planning; 4. Plan Implementation; 7. Achievement of Management Objectives; 8. Contractual Obligations

Criterion: 3.7. Contingency Plan; 4.1 Plan Assessment; 7.2 Assessment of Objective Achievement; 8.1.2 Wood Supply Commitments

Procedures: 3.7.2 Assess whether the planning procedures used for the contingency plan followed the requirement
3.7.3 Assess whether the rationale for the contingency plan was appropriate in the circumstances
4.1.1 Modeling assumptions
7.2.2 Assessment of the progress towards achieving each objective
8.1.2.1 Determine whether wood supply commitments and any special conditions have been complied with

Background Information and Summary of Evidence: The audit team inspected approximately 3,000 ha of area treated in June 2007 by aerial application of a biological pesticide (Btk) to control an outbreak of jack pine budworm. The 2008-09 Annual Report notes that the spray was successful so no further work was required. There was no visible distinction between treated and untreated forest observed by the audit team by air but such an assessment may be premature at this time.

The pest management proposals for 2006 and 2007 were reviewed and found to have met the FMPM requirements in terms of content. The documents were complete and well written; however, the evaluation of options lacked rigour and meaningful quantitative analysis.

Discussion: The treated area viewed by the audit team encompassed a marten core that is deferred from harvest to maintain marten habitat and large areas of "interior" old forest. Older boreal forest cover types, especially jack pine, serve ecological functions through the mortality of the pine overstory. As the dominant trees die they provide habitat structure for marten and other species. The value of trying to "preserve" the jack pine in marten core areas is questionable. MNR representatives suggest that the main reason this strategy was pursued was to reduce the risk of catastrophic fire and this may indeed have a favourable benefit-cost ratio but the supporting analysis is limited.

Conclusion: The pest management proposals for 2006 and 2007 were reviewed and found to have met FMPM requirements in terms of content. The documents were complete and well written. The required management options such as no treatment, modified harvest strategies and insecticide applications were evaluated by the program planning team. However; the evaluation of options lacked rigour and was supported by a minimal level of quantitative analysis. It appears that the decision to spray the biological pesticide Btk was made and the pest management proposal was then drafted to meet the FMPM requirements rather than giving serious consideration to other management options. Several planning team members confirmed that, in hindsight, this was indeed the case but it was necessary to quickly respond to the outbreak. There were also issues in assembling the data at the regional scale to complete a detailed analysis of options. If the program is to continue, a more rigorous cost-benefit analysis should be completed. Future outbreaks will surely occur and MNR should prepare for this event by, at the very least, preparing input files for regional level analyses.

Recommendation 4: MNR Region must develop the capacity to conduct risk based cost benefit analyses of proposed pest management programs in advance of future outbreaks.

Independent Forest Audit – Record of Finding **Recommendation 5**
Principle: 4. Plan Assessment and Implementation **Criterion:** 4.1 Plan assessment **Procedure:** 4.1.1 Assess whether the FMP was appropriate in the circumstance
Background Information and Summary of Evidence: A number of objectives in the 2004-2024 FMP and 2009-2012 Contingency Plan had targets based on the 'natural bounds of variation'. The natural bounds of variation were derived from +/-20% of the highest and lowest points of the Natural Benchmark (NB). The issue with this is that the benchmark starts at the current condition that had over-representation of mixed wood and jack pine stands and under-representation of spruce. In addition, the objective targets were not linked to the trend line of the NB. The Natural Benchmark developed for the plan deviated in several ways from the stated natural condition and one of the FMP targets (pg. 81) "…move toward area by forest unit as represented by previous forest inventories…"
Discussion: The bounds of natural variation were exaggerated, i.e. the lower bound for spruce was likely lower than natural while the upper bounds for jack pine and mixed wood were higher than normal. Thus, the target of staying within the natural bounds could be met while the management strategy moves away from the NB. For example, the NB indicates a slow steady rise of jack pine into the future but the selected management strategy decreases slightly through time. Instead of reducing the current over-representation of mixed wood and jack pine stands, the NB maintains/increases these types and spruce decreases. It is mentioned in the FMP that the relatively short fire cycle determined for the Whiskey Jack Forest favoured jack pine over black spruce. The fire cycle should have been altered to allow development of an appropriate NB.
Conclusion: The bounds of variation used were exaggerated for select forest units and were not appropriate for use in objective target setting. The natural benchmark developed for the 2004-2024 FMP and 2009-2012 Contingency Plan does not reflect the development of a natural forest.
Recommendation 5: The Forest Manager must ensure that, if required, the Natural Benchmark (or equivalent) developed for the next FMP better reflects actual conditions and that, if required, targets/desired levels (or equivalent) for appropriate objectives in the next FMP include consideration for the Natural Benchmark trend line.

Independent Forest Audit – Record of Finding **Recommendation 6**
Principle: 4. Plan Assessment and Implementation **Criterion:** 4.3 Harvest **Procedure:** 4.3.1 Assess in the field the implementation of approved harvest operations
Background Information and Summary of Evidence: The 2004-2009 FMP included moose as one of the featured species on the Whiskey Jack Forest. The plan further outlines how moose habitat would be considered in the layout of cutblocks including "… irregularly, shaped and sized cuts with scattered shelter patches…" Wildlife habitat objectives include an objective for moose habitat which identifies a shelter patch strategy: "Where harvest blocks exceed 100 ha and the 'edge of cover' to 'edge of cover' distance potentially exceeds 400 m, suitable shelter patches will be retained within the harvest block." During the field audit, a number of harvest blocks were visited that were to include moose shelter. In four cases, moose shelter patches had been harvested and had not been left as required.
Discussion: The discussion provided in the FMP clearly explains the reason for including moose shelter patches. Maps included in the auditor field binders illustrated the desired location of the shelter patches but harvest operations did not abide by the plan.
Recommendation 6: The Forest Manager must ensure that moose shelter patches are retained as specified in the FMP.

Independent Forest Audit – Record of Finding **Recommendation 7**
Principle: 4. Plan Assessment and Implementation **Criterion:** 4.3 Harvest **Procedure:** 4.3.1 Assess in the field the implementation of approved harvest operations
Background Information and Summary of Evidence: Site disturbance in the form of rutting was identified as an issue in the 1999-2004 IFA. This problem has been completely eliminated on all sites examined during this audit. However, a number of sites viewed showed signs of compaction of fine textured soils (e.g. reduced regeneration of trees along machine routes) that is contributing to decreased stocking.
Discussion: The fine textured soils common to portions of the Forest are vulnerable to compaction and many sites showed evidence of this type of damage. Based on records and interviews many of these sites were supposedly harvested during the winter period to reduce site disturbance but there are very obvious areas where trees are not regenerating naturally, due to compaction of soils by equipment.
Conclusion: These sites cannot be operated upon during wet or non-frozen periods.
Recommendation 7: The Forest Manager must ensure that operators refine their work methods on fine textured soils to avoid operating during wet or non-frozen periods.

Independent Forest Audit – Record of Finding **Recommendation 8**
Principle: 4. Plan Assessment and Implementation **Criterion:** 4.1 Plan assessment **Procedure:** 4.1.1 Assess whether the FMP was appropriate in the circumstances.
Background Information and Summary of Evidence: The inventory update for the 2009-2012 Contingency Plan was relatively good but FTG record updating completed during the audit term was not always accurate. FTG information in the inventory was compared to actual field visits during the audit. Some large discrepancies were noted. For example, some areas dominated by jack pine with a small spruce component were recorded in the inventory as spruce stands with a small component of pine; the opposite was also found.
Discussion: Small and infrequent discrepancies are common when reviewing Forest Resource Inventory (FRI) attributes, but absolute disagreement of working group should rarely occur. In the 10% sample taken by the audit team, there were several instances of absolute disagreement of working group. Therefore, the quantity and significance of discrepancies noted by the audit team in the sample reviewed suggests a systematic issue with data input and is not categorized as an occasional typographical error. The monitoring section contains a full account of the silviculture monitoring program including FTG assessed during the term.
Conclusion: In preparation for the next FMP, FTG records must be accurately brought into the inventory.
Recommendation 8: The Forest Manager must ensure that the inventory is reviewed and verified for accuracy with respect to Free to Grow records updated during the audit term.

Independent Forest Audit – Record of Finding Recommendation 9
Principle: 4. Plan Assessment and Implementation **Criterion:** 4.4 Renewal **Procedure:** 4.4.1 Effectiveness of renewal prescriptions
Background Information and Summary of Evidence: Site preparation was under-achieved during the audit term - about 7,800 ha of 15,922 ha planned was completed (~50%). All site preparation during the term was completed by a single contractor using a trencher. Site preparation viewed at almost every site visited was often too light and spacing was too wide between passes. MNR SEM assessments mirror the audit findings.
Discussion: Light, wide site preparation led to reduced planting spots on most sites. Fill planting will be required to ensure stocking/density levels can be met on many of these sites.
Conclusion: Site preparation must be monitored to ensure an adequate number of quality planting spots are created.
Recommendation 9: The Forest Manager must ensure that site preparation results in the production of planting spots of the quality and quantity appropriate to meet plan objectives.

Independent Forest Audit – Record of Finding Recommendation 10
Principle: 4 Plan Assessment and Implementation **Criterion:** 4.4 Renewal **Procedure:** 4.4.1 Effectiveness of renewal prescriptions
Background Information and Summary of Evidence: It was noted from Annual Reports that few white spruce, red pine or white pine were planted during the term (11,900, 5,500 and zero, respectively).
Discussion: Several sites audited had a significant pre-harvest white spruce component and at least one site had red pine but these species were not included in the renewal of these areas. Based on the number of seedlings of these species (see above), approximately 15 to 20 ha would have been planted during the audit term (assumes a 20-30% mix of these species rather than pure planting) – this area(s) was not included in the audit sample. According to the 2008-09 AR (final AR for the 2004-2024 FMP), during the audit term 1,324 m^3 of Pr and 110 m^3 of Pw was harvested as well as an undisclosed amount of Sw (planned Sw was 8% of all spruce volume but actual spruce volume harvested was supposedly only ~ 527 ha of Sb although there was evidence of Sw harvest at several audit sites). Based on a conservative value of 5% of the spruce harvested during the term being Sw, plus the Pr and Pw harvest values above, approximately 220-500 ha should have been planted with a mix of Pr, Pw or Sw during the 2004-09 period just to maintain these species on the landscape.
Conclusion: The plan target to enhance red and white pine on the Forest will not be met unless treatments include these species on appropriate sites.
Recommendation 10: The Forest Manager must ensure that planting of red and white pine occurs on appropriate sites.

Independent Forest Audit – Record of Finding **Recommendation 11**
Principle: 4. Plan Assessment and Implementation **Criterion:** 4.4 Renewal **Procedure:** 4.4.1 effectiveness of renewal prescriptions
Background Information and Summary of Evidence: Slash management during the audit term was variable. At the beginning of the audit term effort was made to pile and burn slash. Despite annual reporting that suggests an effective burning program during these years, slash piles were often left unburned or partially burned. The company ceased the slash management program from 2007 to 2009 - slash was left unpiled and unburned along roadsides.
Discussion: Recommendations have been provided in at least the two previous audits to improve slash management. Slash management has been, and continues to be, an issue on the Forest.
Conclusion: If left untreated, piled or unpiled slash will effectively remove large areas of productive land from the land base, likely for decades.
Recommendation 11: MNR Kenora District must ensure that all blocks harvested during the audit term are reviewed for slash management and, where established regeneration will not be affected **a) slash be piled and burned or otherwise removed to allow regeneration of productive land, or** **b) if natural regeneration of these areas is not expected, then treat the area to ensure regeneration.**

Independent Forest Audit – Record of Finding
Recommendation 12

Principle: 4. Plan Assessment and Implementation

Criterion: 4.4 Renewal; 4.5 Tending and Protection

Procedure: 4.4.1 effectiveness of renewal prescriptions
4.5.1 gaps between the planned and actual levels of each type of tending

Background Information and Summary of Evidence: Due to the under-achievement of site preparation, a large component of the planting program was direct plant (i.e. planted without site preparation). As noted, site preparation was often too light and widely spaced to provide the requisite number of planting spots but planting viewed on prepared areas was generally well done with good choice of micro-site. However, wide spacing and missed areas was common on most areas that were direct planted.

A review of planting density from the ARs indicates a pronounced reduction of seedlings per hectare during the audit term – average densities started at just over 2,000 seedlings/ha in 2004-05 and decreased to 1,334 seedlings/ha by 2008-09.

Seeding occurred on 2,100 ha of 7,780 ha planned (~27%). Many of the sites scheduled for seeding were planted instead. This was noted as appropriate during the field review since many of these sites were too competitive for seeding. However, other areas currently scheduled for planting could be effectively site prepared and seeded. Many areas that were seeded were not well stocked and may not meet targeted stocking rates.

No chemical, mechanical or manual plantation cleaning occurred during the audit term even though 8,737 ha were planned. This was confirmed by the field audit that included many sites that had heavy shrub or hardwood tree competition of planted and natural conifer trees. Some older areas deemed FTG also had hardwood competition.

According to silviculture monitoring completed during the audit term, about 22,000 ha of older disturbed area requires competition control in order to meet regeneration standards.

Discussion: Direct planting is a viable option on many sites but must be closely monitored to ensure plan objectives can be met.

Seedling densities were apparently reduced to account for natural ingress; however, the reliability of ingress was not demonstrated in silviculture monitoring results and was not witnessed during the audit. Ingress was sparse on many of the sites viewed and was generally limited to jack pine on shallow soiled/rocky upland patches and black spruce on some lowland sites. Otherwise, shrubs, hardwood species and occasional balsam fir occupied large portions of many sites.

The audit team believes that under-stocking of seeded areas is mainly a result of low germination due to light and wide site preparation. Seed germination potential, timing, and rate of application of seed were not deemed to be cause for the low germination.

The lack of cleaning, particularly on areas planted and seeded, is considered by the audit team to be a crucial finding. Many sites viewed require some form of competition control to meet plan objectives.

The company confirmed the extent of the issue in the 2007-08 AR:

> *The limited tending on the forest may impede achievement of the forecasted forest condition described in the FMP. The inability to economically provide opportunity for optimum tree growth, could over time change the species composition of the Forest by faster growing (poplar, white birch) becoming more frequent and slower growing, shade intolerant species (jack pine, spruce) becoming less frequent on the Forest. This change will impact the local forest users dramatically. Similarly, recent renewal efforts may not result in expected results due to lack of tending operations, generating an increase in areas declared not sufficiently reforested.*

Inadequate tending was an issue raised during the previous two audits and is considered the most significant issue on the Forest in this audit. Interestingly, the tending issue on the Forest has changed from one of a perceived or real over-application of herbicide in the past to the outright abandonment of the program. In the 1994-99 IFA, issues were raised prior to and during the audit concerning the pre-disposition to conifer renewal by the company in situations where pre-harvest hardwood was a large component of the sites. A concern was the significant reduction in the poplar component where block application of aerial herbicide could not easily avoid poplar concentrations. The 1994-99 IFA audit team expressed concern whether some spraying was in fact necessary and whether each candidate spray block received sufficient inspection one year in advance of planned treatment. The auditors recommended that a thorough field assessment of candidate spray blocks occur to ensure prudent use of herbicide.

Spray assessment records and correspondence between Abitibi and MNR reviewed for the 1999-2004 IFA indicated that there were still significant problems with the spray program at the time, particularly early in the 1999-2004 term. Problems included variability in determination of areas requiring tending, areas where the treatment failed and areas being sprayed or re-sprayed that were already free-growing. These problems appear to have caused a lack of confidence by MNR that Abitibi was applying herbicide judiciously. As a result, proposed tending treatments were suspended while MNR and Abitibi representatives jointly enhanced the survey methodology.

Even though the new survey methodology was amended to the 1999-2004 Whiskey Jack Forest FMP in early 2001, the planned tending program was suspended fully by MNR for two years and partially in one year of the five-year term. In addition, Abitibi chose to suspend the vegetation control program in the final year of that audit term while discussions were taking place with Grassy Narrows First Nation, a community that is generally against the use of herbicides.

Because several artificial renewal sites on the Whiskey Jack Forest were in need of tending at the time to meet plan objectives, the audit team for the 1999-2004 IFA recommended that Abitibi implement an approved vegetation control program. As noted, no vegetation control program occurred during the 2004-09 term. Document review suggests that the company considered replacing aerial spray with ground spray for several candidate vegetation management sites; however, ground spray was subsequently also abandoned. Documents also reveal that the company has chosen not to spray in order to avoid the anticipated political backlash from Grassy Narrows First Nation.

Some older FTG areas viewed during the audit were vigorous and composed of almost pure conifer. These areas demonstrate the capacity of the Forest under an effective competition control regime and are the model for the Desired Future Forest Condition as described in the FMPs.

Conclusion: There will be a need for fill planting on most sites planted during the audit term to meet plan objectives. Many areas seeded during the audit term will require fill plant/re-seeding to meet plan objectives. In the absence of a competition control program, the Desired Future Forest Condition described in the 2004-2024 FMP and the 2009-2012 Contingency Plan will not be achieved. Site preparing, planting and seeding of areas without effective competition control is also viewed as a loss of value. The combined effort of tending requisite areas renewed during the audit term and older stands to achieve FTG status will be considerable.

Recommendation 12: MNR Kenora District must ensure that:

a) a review is conducted of all areas planted and seeded during the audit term and that fill planting or re-seeding occurs as necessary to support the achievement of FMP objectives,

b) a review of all sites harvested during the audit term that are forecast to become conifer-leading forest units is conducted, and that tending occurs where necessary so that plan objectives can be met.

Independent Forest Audit – Record of Finding
Recommendation 13

Principle: 4. Plan Assessment and Implementation

Criterion: 4.6 Renewal support

Procedure: 4.6.2 Assess whether actual tree seed collection and nursery stock production is appropriate for the site conditions encountered on the management unit.

Background Information and Summary of Evidence: Seed storage was reviewed during the audit. At the time of the audit two of three jack pine seed lots stored will not meet the annual requirements noted in the 2009-2012 Contingency Plan – there is actually no jack pine seed for seed zone 11. The following table indicates amount of jack pine (Pj) seed stored (X 000,000) versus the need according to the Contingency Plan. Orange indicates less than one year of seed available and yellow indicates less than two years.

seedzone	Pj stored	Pj need CFMP	Years seed CFMP
9	50	50	1
10	11.4	14	0.8
11	0	7	0

If average usage from the 2004-09 term is used as a gauge of future need, only one seed lot of each species is deficient for annual requirements (Pj seed zone 11).

Discussion: Recent diminished harvest levels will reduce the need for seed but renewal support needs to be planned and available for full utilization. In addition, remedial work needed as a result of this audit will increase the demand for seed.

Conclusion: There should be at least a few years worth of seed stored for each species/seed zone combination on the Forest.

Recommendation 13: The Forest Manager must ensure that seed collection and storage meet the needs of the renewal program.

Independent Forest Audit – Record of Finding **Recommendation 14**
Principle: 4. Plan Assessment and Implementation **Criterion:** 4.4 Renewal **Procedure:** 4.4.1 Consider whether there are any gaps between the planned and actual levels of each type of renewal activity seen in the field.
Background Information and Summary of Evidence: New FOPs were selected for many stands during the audit term. For example, direct planting and no tending options were often chosen over more intensive prescriptions. It appears that reducing silviculture cost, rather than modifying operations according to actual field conditions, was the main reason for changing from preferred to alternate prescriptions in many cases. The cycle of silviculture cost reduction started with selecting less intensive/costly options to implement in the field, building a surplus in the Forest Renewal Trust Fund (FRTF) and then using the surplus as evidence in the request to reduce contribution rates. Through requests by the company, the FRTF contribution rate for spruce, pine and fir was reduced from $6.00 per cubic meter in 2005-06 to $5.00 in 2006-07 and to $3.00 in 2008-09.
Discussion: In spite of MNR Area Forester analyses and silviculture effectiveness monitoring that indicated significant issues with the silviculture program, as well as FTG results that showed that regeneration standards were often not being met; MNR granted the renewal rate reductions. In addition, declining contributions (mainly through reduced harvest levels) led to the FRTF minimum balance not being maintained, as required.
Conclusion: Plan objectives and the desired future forest condition on many sites will not be achieved with the options chosen, particularly in light of the operational issues and reduced funding noted. Adequate renewal funding is needed to ensure plan objectives can be met. Additional funding will also be needed to fulfill actions for several recommendations in this audit report.
Recommendation 14: MNR Kenora District must review the Forest Renewal Trust Fund rates particularly for spruce / pine / fir and assign rates appropriate for meeting plan objectives.

Independent Forest Audit – Record of Finding
Recommendation 15

Principle: 4. Plan Assessment and Implementation

Criterion: 4.7 Access

Procedure: 4.7.1 Assess whether roads have been constructed, maintained, and decommissioned to minimize environmental impacts and provide for public and operator safety.

Background Information and Summary of Evidence: During the field portion of the audit, several harvest blocks were viewed where road rehabilitation should have occurred. For example, Block 4.721 and Block 4.760 had roads that would serve no further purpose and rehabilitation would reduce loss of productive area. Although Block 4.760 also had excessive road building, this was the only instance of this found on the audit.

Example of an excessively roaded area that should have been rehabilitated.

Discussion: Road rehabilitation can provide a means to effectively return land to the productive land base as well as eliminate unnecessary and disproportionate loss of productive land where excessive road building has occurred. Where roads will serve no further purpose, be it for forest management or other uses, strategies to rehabilitate roads can result in returning roaded areas to the productive landbase.

Conclusion: Where excessive road building has occurred, efforts need to be made to rehabilitate roads.

Recommendation 15: The Forest Manager must develop a road rehabilitation strategy for the next FMP to ensure that unwarranted roads are rehabilitated and returned to the productive forest landbase.

Independent Forest Audit – Record of Finding
Recommendation 16

Principle: 4. Plan Assessment and Implementation

Criterion: 4.1 Access

Procedure: 4.7.1 Assess in the field the implementation of approved access activities

Background Information and Summary of Evidence: During the field portion of the audit, numerous water crossings and drainages were examined. Marked improvements were noted in water crossing installations from that described in the past IFA. Cross drainage installations were also noted to have improved.

Although improvements were noted, water crossing installations that were performed in winter were found to be inadequate or failing. Erosion of surfaces of winter roads and unstable slopes of water crossings was found at several crossings that had been installed during the winter.

Examples of failing water crossing sites where work had been performed during the winter (aerial view on left).

Discussion: Water crossings are particularly challenging to install during winter months. Even with adequate care a winter installation can fail as snow pack melts and frozen soil thaws. Often harvest operations are completed before spring thaw and failing water crossings can go unnoticed. Even properly installed crossings can fail during and after spring thaw.

Conclusion: Monitoring is required to properly address the potential failure of water crossings that are installed during the winter. A monitoring program should ensure that all water crossings that are installed during the winter are inspected after the spring thaw following their installation.

Recommendation 16: The Forest Manager must develop a monitoring program to ensure that all water crossings installed during the winter are inspected immediately following the first spring thaw after their installation, and incorporate the monitoring strategy into the FMP.

Independent Forest Audit – Record of Finding
Recommendation 17

Principle: 4. Plan Assessment and Implementation

Criterion: 4.1 Access

Procedure: 4.7.1 Assess whether roads have been constructed, maintained, and decommissioned to minimize environmental impacts and provide for public and operator safety.

Background Information and Summary of Evidence: A number of aggregate pits were viewed during the field audit. All of the pits except one were found to be in good condition, the result of the cooperative effort between Abitibi and MNR to monitor and rehabilitate pits where necessary. An example of a typical rehabilitation is shown in the following figure.

One aggregate pit was found to have been operated since the rehabilitation effort had been completed without proper rehabilitation in the interest of public safety. Progressive rehabilitation needs to consider public safety at all times during the life of a pit. Although this was the only instance of a pit that needed work, the audit team gives a recommendation to ensure remediation of the concern. The following photograph illustrates the condition of this pit at the time of the site visit.

Discussion: This is a Category 9 pit with no specific requirement for rehabilitation until final rehabilitation. However, progressive rehabilitation, as outlined in the Aggregate Resources Act, R.S.O 1990, c. A.8 should be given full consideration, particularly in the interest of public safety.

Recommendation 17: The Forest Manager must ensure that the interests of public safety are paramount for establishing pit rehabilitation requirements for all pits at all times.

Independent Forest Audit – Record of Finding
Recommendation 18

Principle: 6. Monitoring

Criterion: 6.3 Silviculture Standards and Assessment Program

Procedure: 6.3.2 Assess whether the SFL/management unit assessment program is sufficient and is being used to provide the required silviculture effectiveness monitoring

Background Information and Summary of Evidence: The company invested significant resources in completing a very large silviculture monitoring program during the audit term. The regular FTG program was completed by company staff mainly by helicopter where appropriate but also through ground plots when more intensive assessment was required (using the Well Spaced Free Growing Assessment method). The FTG program totalled 18,140 ha of 28,243 ha planned for the 2004-09 term (~64%). The under-achievement was partially due to reduced activities during the audit term but was also due to undertaking the assessment of a very large area categorized in the inventory at the time as barren and scattered (i.e. backlog). The backlog area was mainly composed of older blow down areas, areas naturally regenerating following fires and areas regenerating following harvest.

The barren and scattered/backlog update project was completed by a contracted firm during leaf-off periods in the fall of 2004 and spring of 2005. The methodology was low-level helicopter fly-through with at least two calibration landings per day. MNR was involved with some of the early meetings between the company and contractor and also participated in the helicopter during the pilot project (a few base maps were completed in the fall of 2004 in advance of starting the entire project). Of the ~72,000 ha reports as surveyed, ~53,000 ha was declared FTG (~74%) - results were included in the 2007-08 Annual Report.

The audit included a ten percent sample, mainly by helicopter, of the regular and backlog update assessment areas. It was found in many of the backlog update areas deemed FTG that the hardwood composition was under-represented and that age and height was under-estimated in the inventory. The extent of the discrepancies between the original survey data and the status of the surveyed areas as observed by the audit tam could only be attributed to inaccurate calls during the original survey.

Completing assessment work during the leaf-off period is the likely source of the under-estimation of hardwood composition noted. Under-estimation of hardwood composition during surveys is a concern because full detection of forest change will be delayed until the next FRI is completed. Age/height issues are discussed in the next paragraph. Other than age, similar issues were found with the regular FTG program while stocking was also sometimes over-estimated and broad stratification was also noted.

From an examination of the backlog update project specifications and through interviews with company, MNR and contractor staff, it was determined that age was based on the year of disturbance i.e. the 1991 Pakwash blow down area was aged as ~14 years old in 2005. While this methodology is appropriate for disturbances where full kill or removal of the entire stand occurs (such as wildfire or clearcut harvest), it is not always appropriate for disturbances such as blow down that may leave considerable standing trees and/or advanced growth. For example, what was found during the audit of the Pakwash blow down area was that most of the regenerating trees were under-story advanced growth from the previous stand that are now approximately 40 years old. These trees are also much taller than what is in the inventory (~10 to 12 m on average versus 3 to 7 m).

Discussion: It is estimated that the barren and scattered survey cost over one-half million dollars to complete (~$6/ha) but timing of the assessment and the methodology required for updating the inventory reduced the accuracy of the product. It is important that future surveys are completed in a manner that allows for accurate hardwood estimation and that the inventory updating process maintains the accuracy of field information.

Conclusion: FTG records updated during the audit term need to be reviewed to ensure the data is accurate. The following recommendation builds on that recommendation by ensuring that the original field data is fully incorporated. The audit team believes that, following the update and verification that will occur as a result of the recommendation provided below, the inventory of barren and scattered areas will suffice for strategic-level planning until the next full inventory is completed.

Recommendation 18: MNR Kenora District must ensure that a review of the original field data of the barren and scattered survey occurs and that the inventory is appropriately updated with this information.

Independent Forest Audit – Record of Finding
Recommendation 19

Principle: 6. Monitoring

Criterion: 6.5 Annual Reports

Procedure: 6.5.1 Assess whether the text, tables and maps including digital information is accurate, complete and in accordance with the applicable; requirements
6.5.2 Assesses progress towards the objectives and targets identified in the FMP
6.5.3 Assess whether the observations and implications accurately reflect the levels of forest operations that have been implemented to date, any implications on achievement of objectives/targets of the FMP and future levels of forest operations

Background Information and Summary of Evidence:

1. Annual reporting during the audit term was fairly well done. Numbers in text and tables were often in agreement and 'to date' summaries were usually correct. However there were some concerns noted regarding the accuracy of some information. For example, the amount of assessment in the 2007-08 and 2008-09 ARs was incorrect and there were discrepancies in values within ARs. For example the 2007-08 AR suggests on one page that 7,199 ha was sprayed for jack pine budworm while on another page over 28,400 ha was sprayed. The latter was found to be correct.

2. Non-compliance (NC) was reported and discussed in the ARs but text regarding the reason for non-compliance and actions taken was cursory. It is unclear from the limited discussion provided how further EMS training is actually addressing recurring NC issues, such as trespass. The ARs also discuss specific road and crossing repairs and maintenance completed each year as required but there is nothing mentioned relative to effectiveness of road use management strategies. This may be due to having only completed decommissioning work in the last year of the plan term and thus having little effectiveness.

3. A large amount of area was assessed for renewal during the audit term. For areas that had been managed, silviculture success (i.e. following the path chosen) and regeneration success (i.e. not following intended path but adequate amounts of acceptable tree species present) was calculated and summarized in the ARs. However, important required information on how silviculture success is affecting plan objectives and other potential implications was not included in the ARs.

   In one AR the following is provided:
   Silvicultural success to the projected forest unit on normal harvest areas and natural disturbed areas was 53% of the area successfully regenerated. The ingress of jack pine and eventual dominance on 1,317 ha of area projected as SPDOM treated with a black spruce planting was the main contributing factor to decreasing the silvicultural success rate. Other contributing factors were the establishment of 437 ha of MIXED and 119 ha of PODOM forest units on projected SPDOM areas.

4. Under-achievement of tending was found to be a considerable issue in the 1999-2004 IFA for the Whiskey Jack Forest. The lack of tending during this audit term raises significant concerns regarding objective achievement and future forest condition.

   The ARs however include little discussion regarding the affect of the lack of tending (e.g.):
   The absence of a chemical tending program is a concern to the success of certain plantations.

   The limited tending on the forest may impede achievement of the forecasted forest condition, as described in the FMP. The inability to economically provided opportunity for optimum tree growth, could over time change the species composition of the forest by faster growing (poplar, white birch) becoming more frequent and slower growing, shade intolerant species (jack pine, spruce) becoming less frequent on the forest. This change will impact the local forest users dramatically. Similarly, recent renewal efforts may not result in expected results due to lack of tending operations, generating an increase in areas declared not sufficiently reforested.

More recent ARs also include the following regarding the lack of tending:
Prompt renewal activities with the use of superior growing stock are assisting to offset the absence of chemical tending.

5. Under-achievement of harvest area, volume targets and most renewal activities is documented in all ARs but there is little discussion regarding how this affects or will affect the achievement of plan objectives.

6. One objective in the 2004-2024 FMP was to move towards the template disturbance frequency through reducing fragmentation on the Forest. The ARs contain minimal information regarding this:
This being the third Annual Report of the 2004 FMP, there is not sufficient data available to mark the progress of meeting the frequency/size distribution objective. Reports for years 4 and 5 would provide a better indication of progress.

Unfortunately there is little provided in the year 4 and 5 reports – from the 2008-09 AR:
Harvesting on 5.3 ha occurred in location ID 561 in 2008-09. The remaining area harvested this year was within contingency blocks amended to the FMP thus were not part of the planned clear cut analysis conducted in the 2004 FMP.

Other notable discussions/assessments missing from some or all ARs:
- the need to increase, maintain or decrease renewal rates
- the reason for non-compliances and kinds of actions taken to mitigate non-conformances
- implications on achievement of long-term management direction not included with the assessment of regeneration success
- effectiveness of use management strategies for roads

Discussion: The ARs generally cover required topics but in depth analysis and discussion is lacking. For example, deviations between planned and actual activity amounts were provided and reasoning was often provided for achievement rates but discussion of how this affected or will affect plan objectives did not occur. Potential implications were sometimes discussed but with little detail. For example, the average silviculture success rate over the term was 71% but the implications of this were not discussed. Some discussion of possible affects of no tending was provided but some text actually raised questions rather than answered questions – e.g. what studies were done to determine how superior growing stock is offsetting the lack of tending? Regarding analysis of planned clear cuts, Table AR-3 in the later ARs indicates a number of planned clearcuts are completed, certainly enough to start discussing movement towards meeting this objective.

Conclusion: ARs should be a clear and accurate presentation of annual forest operations but are often inadequately and/or hastily prepared. ARs normally meet the basic accounting/summary of operations FMPM requirements but miss the deeper discussions required of the FMPM. Moving forward, this should be considered during development of ARs.

Recommendation 19: The Forest Manager must ensure that:
a) all information in the Annual Report is confirmed for accuracy prior to finalization,
b) future Annual Reports contain all required discussions including progress towards achievement of plan objectives, potential implications of operations on future operations and effectiveness of road use management strategies.

Independent Forest Audit – Record of Finding
Recommendation 20

Principle: 7. Achievement of Management Objectives and Forest Sustainability

Criterion: 7.1 Year Ten Annual Report

Procedures: 7.1.1 to 7.1.7

Background Information and Summary of Evidence:

1. As per the regular ARs audited, there were inconsistencies noted in the Year 10 AR. For example, there were discrepancies between the individual AR harvest areas and associated harvest volumes versus the total in the Year 10 AR; however, all renewal and compliance values were found to be correct. There was also a difference in area assessed – individual ARs total 19,162 ha vs the Year 10 AR total of 17,235 ha. The 2007-08 and 2008-09 ARs had errors that led to this difference.

2. The Year 10 AR included a review of renewal and tending operations during the term as well as expenditures, silvicultural effectiveness and harvest/renewal trends. Section 4.2 also included a discussion of renewal trends, etc. but, according to the author, "the change in forest units in the 2004-2024 FMP makes it difficult to compare between terms". Lack of aerial spray and likely changes to forest composition and the inability to provide the preferred future forest condition was also noted as was the increased use of planting without site preparation. Although "this practice has been limited to the least competitive sites, until herbicides can be used", direct planting viewed during the audit occurred on a variety of sites, including some very competitive sites.

   There was no discussion in the Year 10 AR regarding changes that may affect future silviculture effectiveness or expenditures and although there were three changes to renewal rates during the audit term, there was no rationale for this in any of the ARs including the Year 10 AR.

   There was no discussion regarding the effectiveness of silvicultural treatment packages that are exceptions to the forest management guides in the text.

3. The Year 10 AR includes the following:
   Many of the model assumptions are difficult to assess for two reasons. The 2009-2012 Contingency Plan carried forward the objectives, strategies, modeling, and targets from the 2004-2024 FMP. The assessment of forest conditions, habitat levels, yield curve adjustments, age class distribution, forest unit classification, etc. were not conducted for the 2009 plan, thus not available for comparison to 2004 targets. Secondly, with only 57% of the forecast harvest area being achieved, targets related to yield, disturbance patterns, silviculture, budgets, etc. may be skewed due to selection and location of harvest allocations.

   This discussion does not meet the FMPM requirements.

4. The Year 10 AR includes a section regarding the 1999-2004 IFA action plan but it is merely a summary of the recommendations and suggestions from the audit and a cursory note that "All recommendations have been addressed in the draft action plan currently in the final stages of approval by the MNR. The status of these action items is completed with the exception of two recommendations".

5. According to Table AR-20 in the Year 10 AR, many of the objectives cannot be assessed because the 2009-2012 Contingency Plan did not run SFMM and the FRI for the 2009-2019 FMP, which was never developed, had some new forest units.

6. Section 4.6.1 of the Year 10 AR includes a Social and Economic Review that focuses on mill closures and the working group developed between MNR and Grassy Narrows First Nation as well as the intended surrender of the SFL by ACCC. This does not meet the FMPM requirements (Part E 4.6.1) that an updated social and economic description be prepared.

7. The FMPM Part E 4.6.2 requires that recommendations be developed as a result of the determination of sustainability and social and economic review. The recommendations are to focus on considerations for the

next FMP including changes to the LTMD and forest operations. Considering the issues noted in ARs and witnessed during the audit, this section should be substantial and should 'set the stage' for the next FMP. Unfortunately, only the following was provided:

Due to the current conditions of the forest industry, many objectives or targets were not achieved during this term. Similarly, the development of the 2009-2012 Contingency Plan by carrying forward objectives and targets from the 2004-2024 FMP did not allow for a complete assessment. The 2011 and 2012 Annual Reports should provide an assessment of achievements for the eight year term (2004-2012).

Discussion:

1. The Year 10 AR was a fairly accurate compilation of activities that occurred during the 2004-09 term but errors still occurred when compared to a summary of the ARs.

2. Some attempt should have been made to analyze the main forest units (pj dom, sb dom, pt dom, mixed wood) to determine renewal trends. Also, it was noted that the analyses contained in the Year 10 AR were not carried forward into the 2009-2012 Contingency Plan since the strategic direction from the 2004-2024 FMP had to be used. It is expected that gains in knowledge made over the audit term and beyond will need to be incorporated in the planning for the next full FMP for the Whiskey Jack Forest. Thus, this work needs to be completed.

3. The requirement is that, based on new information, operations, etc., the 2004-2024 FMP assumptions are reviewed so that modifications/revisions can occur in the next FMP. Although the next plan turned out to be a three year Contingency Plan for 2009-2012 that used the strategic direction from the 2004-2024 FMP, this review still needs to be done for future use (i.e. the development of the 2012-2022 FMP) which was already under way during the conduct of the audit.

4. The text provided in the Year 10 AR does not fulfill the FMPM requirement that the text summarize the IFA action plan, including a discussion of the progress on implementation and any implications.

5. SFMM could have been re-run at the end of the term with the actual harvest areas to determine the trends. Likewise, the inventory for the 2004-2024 FMP could have been updated with accruals and depletions to 2009 without changing the forest units.

6. The Social and Economic Review does not meet the FMPM requirements (Part E 4.6.1) that an updated social and economic description be prepared.

7. The proposed delay of required work to another AR does not meet FMPM requirements.

Conclusion: Overall, the tendency in the ARs reviewed, including the Year 10 AR, was to provide cursory explanations for many important trends, delay required analyses and give poor explanations for not completing required work. The level of analysis and discussion in the Year 10 AR is deemed to be sub-par and inadequate and a recommendation is made to revise the AR to meet requirements.

Recommendation 20: MNR Kenora District must ensure that the 2008-09 Year 10 AR is revised to include the following:

a) analysis/discussion of changes that may affect future levels, effectiveness and expenditures of renewal and tending operations,
b) analysis/discussion of effectiveness of silvicultural treatment packages that are exceptions to the forest management guides,
c) review/discussion of needed modifications or refinements to modeling assumptions,
d) a summary of progress on implementation of the 1999-2004 IFA Action Plan,
e) an update of the inventory and running of SFMM at plan end (2009) to determine objective achievement,
f) an update of the 2004-2024 FMP social and economic description, and
g) based on the determination of sustainability and the social and economic review, develop recommendations for the next FMP.

Independent Forest Audit – Record of Finding
Recommendation 21

Principle: 8. Contractual Obligations

Criterion: 8.1.9 Audit action plan and status report

Procedure: 8.1.9 Assess whether the action plan was prepared in accordance with requirements.
8.1.9.2 Assess whether status report was prepared in accordance with requirements.

Background Information and Summary of Evidence: During the 2004 IFA one of the key recommendations was that the Action Plan Status Report for the 1999 IFA be submitted, to allow MNR to act on the recommendation by the 1999 IFA audit team that the licence be extended. The Minister typically requires demonstrated progress on the actions associated with recommendations arising from an IFA before the licence is extended; the audit action plan status report documents that progress and provides supporting information necessary to make such a decision. As of the start of the 2009 IFA the 1999 IFA action plan status report was not finalized; however the licence was extended in 2006.

The 2004 IFA action plan had not been finalized; and therefore neither had the status report been prepared at the time of the 2009 IFA. The 2004 IFAPP required the action plan be prepared subject to written MNR approval within two months of receipt of the final audit report, unless otherwise directed by the Minister. The audit report was submitted in April 2005. There was no evidence that an extension to the submission time for the audit action plan was granted. The audit team reviewed email records mostly from April 2008 to June 2009 between the MNR Northwest Region and SFL representatives and/or MNR staff regarding preparation of the audit action plan and status report, including the 1999 IFA status report. There was only a single record of correspondence on the subject between August 2005 and April 2008. The audit team also spoke with MNR Kenora District staff, the Northwest Region representative and an SFL representative on this subject.

Conclusion: It appears that the strained working relationship between the District and ACCC and priority given to what were deemed other more pressing tasks were at the root of the failure to meet IFAPP action plan and status report submission requirements. The lack of regular communication between all parties with responsibility to prepare the action plans and status reports also appears to be a contributing factor in the protracted delays in submission. Despite this, the delays in submission of these documents did not significantly impact implementation of actions to address the recommendations arising from the 2004 IFA.

Recommendation 21: The MNR Kenora District Manager and the Forest Manager must ensure that the audit action plan and status report comply with all IFAPP submission requirements.

Appendix 2 – Management Objectives Tables

2004-2024 Forest Management Plan - Whiskey Jack Forest

Objective		Assessment - Auditor Comments
Forest Diversity Objectives		
Forest Structure	Maintain or move toward a natural age class structure that is within the estimated bounds of natural variation for the Whiskey Jack Forest through management planning and silviculture.	Not Met - due to declining harvest rates related to economic factors outside the control of forest managers.
Forest Composition	Maintain or move toward a range of forest units and age classes within the bounds of natural variation as developed for the Whiskey Jack Forest.	Not Met - due to lack of tending.
Natural Disturbance Emulation	Emulate natural disturbance patterns, characteristic of the Whiskey Jack Forest.	Met - NDPE guidelines applied appropriately.
Social and Economic Matters Objectives		
Sustained Wood Supply	Provide a predictable and continuous supply of wood to the forest products industry from the Whiskey Jack Forest.	Not Met - due to ongoing dispute with Grassy Narrows First Nation and market collapse, which are factors outside the control of forest managers.
Working with Aboriginal Peoples	Work with local Aboriginal peoples, whose communities are situated in or adjacent to the Whiskey Jack Forest, to identify and implement forest operations (harvest, access, renewal, maintenance and protection) that will maintain or enhance social and economic benefits to Aboriginal peoples. Targets (non-quantifiable): • Provide opportunity to harvest, through overlapping license, 10,000 m^3 on an annual basis to members of the Grassy Narrows First Nation. • Provide opportunity to harvest, through overlapping license, 10,000 m^3 on an annual basis to members of the Wabauskang First Nation.	Met - 52,868 m^3 allocated for harvest by OFRL holders in Table FMP-23. No volumes reported as harvested by Grassy Narrows FN. Wabauskang FN community member harvest averaged 26,000 m^3 per year. Tree planting and tree thinning work conducted by Aboriginal contractor.
Forest Resources for Personal and Commercial Use	Make available incidental volumes of timber for other uses such as fuelwood, building logs, furniture and other materials. (These incidental volumes will come from areas allocated within this FMP).	Met - ARs note personal use of fuel wood during term. MNR confirmed availability.

Objective		Assessment - Auditor Comments
Tourism, Commercial and Non-commercial Users	Select and prescribe forest operations (harvest, renewal, maintenance, protection and access) that consider the requirements of other forest users, allowing continued use of the forest while minimizing conflict between forest operations and other forest users.	Met Road systems were generally open for public use and roads were maintained while company was operating. 43 tourism operators responded and 33 accepted invitation to participate in RSA process – the group was further refined as individuals inspected the proposed area of operations maps. 13 RSAs were negotiated and drafted for signature. These RSAs provided the basis for tourism AOC prescriptions for the Plan. Public consultation process was followed; AOC planning provided opportunities for discussion and protection of known values.
Other Land Uses	Conduct forest management activities in a manner that considers private land, parks and other land designations or values.	Met - AOC prescriptions were followed for all AOCs examined in the field portion of the audit.
Cultural Heritage Values	Protect identified, registered, or high potential archaeological and cultural heritage sites from conditions that could potentially damage or cause an increase in rates of deterioration.	Met - High Potential Cultural Heritage AOCs applied and implemented; AOC prescription permits timber harvest only when ground conditions prevent surface soil damage – no SIP – winter roads permitted when ground frozen and <1% of AOC is disturbed – no ditching.
Provision of Forest Cover Objectives		
Selected Wildlife Species	Provide suitable/preferred habitat within the bounds of natural variability for the selected wildlife species within the Whiskey Jack Forest.	Met in planning phase. Only Great Grey Owl falls below the null and only by 1.65% for one term. Silviculture direction of the FMP was not implemented thereby compromising the ability to meet this objective in the long term. See Recommendation 3.
Woodland Caribou	Maintain or improve contribution of the Whiskey Jack Forest to continued range occupancy and healthy populations of woodland caribou in Northwestern Ontario.	Met - The Northwest portion of the Whiskey Jack Forest is managed under Woodland Caribou guidelines. No forestry activities had occurred in this area during the audit term.

Objective		Assessment - Auditor Comments
Marten	Maintain or move toward having 10-20% of capable marten habitat area in suitable conditions arranged in core areas of 3,000 to 5,000 hectares.	Not Met FMP only provides for 3.7% in 36 cores - deferral of these 36 cores for the next 60 years, providing there is no natural disturbance, will provide for an increase of suitable marten habitat to 70,603 ha (10.4% capable) by 2064. Silviculture direction of the FMP was not implemented thereby compromising the ability to meet this objective in the long term. Without implementing planned silviculture direction future marten habitat is unlikely to improve significantly. See Recommendation 3.
Moose	Retain a year round supply of suitable habitat (including foraging and winter habitat) for moose on the Whiskey Jack Forest.	Partially Met - See Appendix 8D, pg. 18 of the 2004-2024 Whiskey Jack Forest FMP. Shelter patches not all refined as planned. See Recommendation 6.
Stick Nests	Provide for the protection of nest sites and associated habitat of bald eagle, osprey, great blue heron and other locally significant forest dwelling raptors.	Met - Accomplished through application of various AOCs associated with each of these species.
Soil	Minimize any possible adverse effects of forest practices on soil quality.	Partially Met - Rutting no longer an issue on forest but compaction of fine textured soils appears to be an issue on some sites viewed. See Recommendation 7.
Fisheries and Water Quality Function	Maintain riparian habitat, water quality and to prevent the harmful alteration, disruption or destruction of fisheries habitat where forest management activities occur.	Partially Met - Riparian AOCs implemented. Water crossings that are installed during the winter need monitoring to address erosion concerns. See Recommendation 16.
Silvicultural Objective		
Silviculture	Apply the most appropriate level of silviculture that will ensure the long-term forest sustainability while consistent with all other objectives of this plan.	Not Met - Planting objective over-achieved but most trees were direct planted. Therefore SIP and seeding under-achieved. SIP too wide and too light, direct plant is resulting in low stocking. Tending almost non-existent. Target stocking and species composition objectives will not be met. See Recommendation 9, Recommendation 10, Recommendation 11, Recommendation 12.

Appendix 3 – Compliance with Contractual Obligations

The following table provides the conditions of SFL No. 542253 for the Whiskey Jack Forest. Each condition is provided on a separate row with comments by the audit team to report on the degree of attainment of the condition.

Licence Condition	Licence Holder Performance
Payment of Forestry Futures and Ontario Crown charges	Met – according to information provided to the audit team by MNR.
Wood supply commitments, MOAs, sharing arrangements, special conditions	According to annual reporting most of the wood supply commitments could have been met during the term. Poor markets were the over-riding issue that led to less than 50% of the planned volume being harvested during the term. The 2009-2012 Contingency Plan intends to meet all wood supply demands. Hardwood veneer (poplar) to Columbia Forest Products: No response from Columbia FP to audit team request for input. Non-veneer aspen and birch to Weyerhaeuser Company Limited: Not Met in 2008 due to Grassy Narrows FN actions. Jack pine, spruce and balsam to Kenora Forest Products Ltd.: Met; mill closed in 2008.
Preparation of FMP, AWS and reports; abiding by the FMP, and all other requirements of the FMPM and CFSA	Partially Met - FMPs and AWSs were generally prepared as required. However errors were noted in text and tables of ARs, in depth analysis was lacking in ARs including the Year 10 AR, and the process for revising forest operations prescriptions was not followed in the AWSs. See Recommendation 19 and Recommendation 20. Partially met with respect to following the planned silviculture plan during the term. Recommendation 9 through Recommendation 13 and related text cover on-the-ground silviculture issues discovered during the audit.
Conduct inventories, surveys, tests and studies; provision and collection of information in accordance with FIM	Met with respect to collection of survey information; however, the information is not being effectively used during planning. See Recommendation 2.
Wasteful practices not to be committed	Met – Utilization was observed to be acceptable, with minor exceptions.
Natural disturbance and salvage SFL conditions must be followed	Met – Salvage of some blown-down timber occurred during the audit term. Planning for this work met requirements.
Protection of the licence area from pest damage, participation in pest control programs	Met – Insect Pest Management Plans covering several forests including the Whiskey Jack Forest were developed and implemented in 2006 and 2007. The company had representation on the planning teams for these plans and worked with MNR to help identify and map affected areas but no plans were made to salvage these areas mainly due to inaccessibility.
Withdrawals from licence area	N/A
Audit action plan and status report	Not Met – Prolonged delays in the preparation, submission and approval of audit action plans and status reports by both the company and MNR Kenora District.

Licence Condition	Licence Holder Performance
	Neither the 1999 IFA Status Report nor the 2004 IFA audit action plan and status report were finalized by the time of the 2009 IFA. See Recommendation 21.
Payment of forest renewal charges to Forest Renewal Trust (FRT)	Partially Met – Regular contributions were made for most of the audit term.
Forest Renewal Trust eligible silviculture work	Met –Verification of maps, records, and fieldwork associated with Forest Renewal Trust Account expenditures for 2006-2007 were found to be accurate.
Forest Renewal Trust forest renewal charge analysis	Analysis conducted, however audit team recommended further review – see Recommendation 14.
Forest Renewal Trust account minimum balance	Partially Met – Minimum balance requirement met in three of five years
Silviculture standards and assessment program	Not Met - Section 16 of the SFL document outlines the silviculture standards requirement: *The Company will implement the necessary silvicultural prescriptions on lands described in paragraph 16.2 herein* (i.e. Category 2 Lands, which are essentially all areas harvested since 1994) *so as to meet the silvicultural standards described in the approved Forest Management Plan for the Whiskey Jack Forest when the silvicultural prescriptions were made, or in accordance with any amendment of that standard.* Considering the field audit findings and the silviculture monitoring results for the audit term, it is clear that the company did not fully meet its obligation with regards to silviculture standards during the audit term. Now that the licence has been officially surrendered, MNR is responsible for this obligation until a new forest management company has taken over. It is expected that completing the actions necessary to meet several recommendations in this audit may lead to fulfilling this requirement. This should be a consideration of prospective forest managers.
Aboriginal Opportunities	Met – Opportunities included wood harvesting, tree planting, slash pile burning, thinning, nuisance beaver control; opportunities provided to participate on the LCC and during forest management planning, including learning opportunities.
Preparation of compliance plan	Met - Company prepared the compliance plan and annual compliance schedule and carried out regular inspections of operations. Inspection reports were prepared and submitted as required. Overall compliance levels were considered acceptable. ACCC developed the Strategic Compliance Plan for the 2004-2024 FMP and Annual Compliance Schedules for each year during the audit term. Due to pending surrender of the SFL, MNR developed the Strategic Compliance Plan for the 2009-2012 Contingency Plan. These documents all met content requirements. ACCC also had an internal prevention/education program during the audit term, which MNR felt met the requirements and needs of forest management on the unit. As noted in the monitoring section of this audit report, there was a significant discrepancy between MNR and

Licence Condition	Licence Holder Performance
	company compliance findings during the audit term and annual reports noted the company's disagreement with some of the ministry's compliance findings. It is hoped that the new management entity for the Forest maintains a cooperative relationship with MNR so that, amongst other things, differences in compliance interpretation can be minimized. Overall, considering the significant sector downturn, contractors going out of business and mill closures, the compliance program delivered during the audit term was acceptable but compliance rates indicate that improvements can be made.
Internal compliance prevention/education program	Met – Implemented through company EMS training programs.
Compliance inspections and reporting; compliance with compliance plan	Met – Compliance plan implemented; inspections conducted and compliance reports submitted.
SFL forestry operations on mining claims	Met – No infractions reported.
SFL or Agreement extension recommendation	None made due to surrender of SFL to the Crown in August, 2009.

Appendix 4 – Audit Process

The Independent Forest Audit Process and Protocol (IFAPP) was developed by MNR to provide a comprehensive and consistent method of evaluating forest management activities on Crown land. The IFAPP (2009) states that the purpose of an Independent Forest Audit is to:

a) assess to what extent forest management planning activities comply with the Forest Management Planning Manual (FMPM) and the Crown Forest Sustainability Act (S.O. 1994, c. 25) (CFSA);
b) assess to what extent forest management activities comply with the CFSA and with the forest management plans, the manuals approved under the CFSA and the applicable guides;
c) assess the effectiveness of forest management activities in meeting the forest management objectives set out in the forest management plan, as measured in relation to the criteria established for the audit;
d) compare the forest management activities carried out with those that were planned;
e) assess the effectiveness of any action plans implemented to remedy shortcomings revealed by a previous IFA;
f) review and assess a licensee's compliance with the terms and conditions of the forest resource licence.

The IFAPP is based on eight guiding principles and contains 158 procedures, 135 of which are applicable to the Whiskey Jack Forest. Of that number a further 15 procedures were not audited due to sampling or by exemption under the IFAPP. The audit procedure serves as a framework to provide a structured approach to evaluating whether or not forest management activities meet the requirements governing forestry practices on Crown land in Ontario. The guiding principles are:

1. Commitment
2. Public consultation and Aboriginal involvement
3. Forest management planning
4. Plan assessment and implementation
5. System support
6. Monitoring
7. Achievement of management objectives and forest sustainability
8. Contractual obligations

MNR categorized the various IFA procedures based on complexity and their potential impact on forest sustainability. The IFAPP directs the audit team to assess through sampling, per audit principle and associated criteria, the three categories of procedures as follows:

- Administrative procedures – low (L) risk: 20-30% of L procedures to be assessed
- Administrative but also having a bearing on sustainable forest management – medium (M) risk: 50-75% of M procedures to be assessed
- Procedures directly related to sustainable forest management – high (H) risk: 100% of H procedures to be assessed

The lower range of the sample scale may be considered for forests certified in accordance with a sustainable forest management standard accepted by Ontario. The following table summarizes the number of procedures selected by the audit team for audit based on the direction provided by the IFAPP.

Table: Summary of the number of procedures selected by the audit team for audit based on direction provided in the IFAPP.

Principle	Procedures Audited by Risk Category							Comments
	Low Risk			Medium Risk			High Risk	
	Applicable (#)	Selected (#)	% Audited	Applicable (#)	Selected (#)	% Audited	Audited (#) (100% of applicable audited)	
1. Commitment	0	-	0	2	0	0	0	The Whiskey Jack Forest was certified to CSA Z809-02 for the majority of the audit term and therefore Principle 1 was considered met.
2. Public Consultation and Aboriginal Involvement	0	-	0	6	5	83	2	Procedure *not* audited: 2.6.1
3. Forest Management Planning	6	3	50	12	8	67	36	Procedures *not* audited: 3.2.1.1, 3.2.1.2, 3.2.2.1, 3.3.2.3, 3.6.2.1, 3.9.2.1, 3.9.3.2
4. Plan Assessment & Implementation	1	1	100	1	1	100	9	
5. System Support	0	-	0	1	1	100	1	Procedure 5.1.1 *not* audited because the Whiskey Jack Forest was certified to CSA Z809-02 for the majority of the audit term.
6. Monitoring	0	-	0	7	5	71	11	Procedures *not* audited: 6.1.2; 6.4.3
7. Achievement of Management Objectives and Forest Sustainability	0	-	0	2	1	50	13	Procedure *not* audited: 7.1.8
8. Contractual Obligations	0	-	0	4	3	75	8	Procedure *not* audited: 8.1.8.1
Totals	7	4	57	35	24	69	80	

The audit process for the Forest consisted of seven components:

1. Audit Plan: KBM prepared an audit plan that described the schedule of audit activities, audit team members and their qualifications, audit participants, and auditing methods. The audit plan was submitted to MNR, ACCC, the Forestry Futures Trust Committee, and the Chairs of the Kenora LCC and the Red Lake District Resource Management Advisory Committee.

2. Public Consultation: Several means of engaging consultation for the audit were used. Utilizing the MNR Kenora District mailing list, KBM mailed letters to numerous parties advising of the audit and inviting their input. Mail-outs included a one-page survey to solicit public input to the audit process. The survey was also available to the general public on the KBM website (www.kbm.on.ca). Newspaper ads were published in four area newspapers prior to the pre-audit meeting advising the public of the upcoming audit, identifying the purpose of the audit and inviting the public to submit comments to the LCC Chair or directly to KBM.

3. Aboriginal Engagement: KBM sent a letter to four Aboriginal communities and the Kenora Metis Association, each with either a direct relationship or involvement in forest management

planning on the Whiskey Jack Forest, inviting their participation in the IFA for the Whiskey Jack Forest. The letter requested their input and encouraged them to contact KBM if they wished to participate in the audit or if they required more information before making a decision. Follow-up phone calls were made during the site visit to encourage a response. In addition, standard public notification letters were sent to other Aboriginal communities and organizations not directly located on the Forest or involved in planning for the Forest.

4. Field Site Selection: The audit team conducted a preliminary site selection prior to meeting with ACCC and MNR staff. Annual Work Schedules and Annual Reports were used to determine the amount and type of forest operations carried out on the Forest during the audit period. A stratified random sample of sites was then selected to ensure that selected sites were representative of a cross section of all activities conducted on the Forest during the audit period. A pre-audit meeting was held in Kenora on August 5, 2009. Part of the pre-audit site visit was spent discussing the preliminary site selection and preparation of field packages with ACCC and MNR.

5. Pre-audit Document Review: Prior to the September site visit, the audit team reviewed documents provided by ACCC and MNR, including the:
    a) Whiskey Jack Forest 2004-2024 FMP and 2009-2012 Contingency Plan
    b) Annual Work Schedules and Annual Reports associated with the 2004-2024 FMP
    c) Comparison and Trend Analysis of Planned versus Actual Forest Operations Report (TAR)
    d) Whiskey Jack Forest Independent Forest Audit 1999-2004 report
    e) Whiskey Jack Forest 1999-2004 draft Independent Forest Audit Action Plan/Status Report.

    The audit team also developed a questionnaire that was circulated to planning team members and other ACCC and MNR District staff prior to the on-site audit to assess their perceptions regarding the effectiveness of specific components of forest management on the Whiskey Jack Forest. The results of the survey provided additional focus to IFAPP prescribed interview procedures that occurred on site.

6. On-Site Audit: The objectives of the field site visits were to confirm that activities were conducted according to plan, that they conformed to provincial laws, regulations, and guidelines, and that they were effective. The opening meeting was held in Kenora on September 14, 2009. During the on-site visit portion of this audit, the audit team spoke with staff of ACCC, MNR, and LCC members. The audit team examined documents, records and maps at the MNR Kenora District office, and spent three days in the field viewing selected sites. Representatives of ACCC, MNR Kenora and Red Lake Districts, MNR Forest Management Branch, and a representative of the Forestry Futures Trust Committee (FFTC) accompanied the audit team during a portion of the field audit.

    Many stops provided the opportunity to audit multiple activities such as harvesting, renewal, values protection, etc. The following table presents the actual sampling intensity for each forestry activity examined on the ground as part of the field site visits. Due to access and time constraints, the audit team relied on a helicopter to reach many of the selected field sites. The helicopter also provided opportunities for overviews of the subject areas, enabling overall examination of target blocks.

7. The closing meeting was held in Kenora on September 21, 2009. This meeting provided a forum for the audit team to present and discuss preliminary audit findings with ACCC, MNR and a representative of the Kenora LCC.

Table: Audit sampling intensity for the Whiskey Jack Forest.

Activity	Total Area or Number (2004-2009)	Area or Number Sampled	Percent Sampled
Harvest (ha)	14,283[1]	1,948	14
Artificial Regeneration (ha)	13,967[1]	1,376	10
Natural Regeneration (ha)	7,068[1]	702	10
Tending	1,369[1]	124	9
Declared FTG - Regular (ha)	12,271[1]	1,495	12
Declared FTG - Backlog (ha)	53,042[2]	7,000	13
Protection (ha)	30,805[1]	3,000	10
Area of Concern Categories[3] (#)	22	10	45
Road Construction (km)	19.2[1]	19.2	100
Specified Procedures Review[4] (ha)	4,107	678	17

[1] Source: draft 2008-09 Annual Report
[2] Source: 2007-08 Annual Report
[3] Area of Concern categories refer to the different types of AOCs present on the Forest. Examples include riparian reserves, cold water fisheries, eagle nests, etc. More than one AOC was associated with some sites selected for review of harvest and renewal operations.
[4] The Specified Procedures Review involved the verification of maps, records, and fieldwork associated with Forest Renewal Trust Account expenditures for 2006-2007.

8. Final Report: The audit results are presented in this report following a brief description of the audit process and the forest licence area under review. Within the report the audit team has made recommendations to address instances of non-conformance to a law and/or policy, or an identified lack of effectiveness in forest management activities.

   Recommendations from this audit must be addressed in an action plan developed by the Forest Manager and MNR Kenora and Red Lake Districts, with input and review by MNR Regional and Forest Management Branch representatives. MNR Regional and Forest Management Branch representatives will also develop an action plan to address any recommendations applicable to matters of forest management within the scope of responsibilities of these departments.

   Suggestions are no longer highlighted in audit reports, nor will they be addressed in action plans. Any suggestions of the audit team are incorporated within the regular text of the report.

Nineteen responses to the public notices and survey were received. Commenter's areas of interest in forest management on the Whiskey Jack Forest were recreation, employment, conservation, LCC, tourism and Aboriginal rights.

Local Citizens' Advisory Committee

Letters were mailed to all current members of the LCC to notify them of the audit and invite their input. The lead auditor attended an LCC meeting in Kenora in August, 2009 to discuss the audit and any concerns the LCC members might have about the Forest. The audit team attended an LCC meeting during the site visit to receive additional input and answer questions. A representative from the Kenora LCC and the Red Lake LCC each participated on one of the field days and a Kenora LCC representative was present during the closing meeting.

LCC representatives interviewed were generally complimentary of the support provided to the LCC by MNR; however concern was expressed by one member that the LCC's opinions were not always welcomed by MNR. Both LCCs stated that attendance by the public at information sessions was low despite the sessions being well organized and informative. It was felt that people typically only attend if they are directly affected by proposed forest management activities. A Kenora LCC representative expressed major concerns with the accuracy of the forest resource inventory, and the reliability of SFMM, citing that the LCC has no expertise to satisfy them of the sustainability of the forest and must rely on the audit.

Aboriginal Communities

A letter was mailed to each of the Aboriginal communities on the MNR District contact list inviting them to participate in the audit. The letter explained that their input is welcomed and encouraged them to contact KBM if they wish to participate in the audit or if they require more information before making a decision. Follow-up phone calls were made to further solicit input. Separate in-person meetings were held with representatives of Wabaseemoong First Nation and Grassy Narrows members of the Forest Management Working Group. Grassy Narrows representatives presented a lengthy list of concerns that it considers unresolved and expressed dissatisfaction with what they consider a lack of meaningful progress in discussions under the Process Agreement with MNR. Wabeseemoong representatives did not state that they had specific significant concerns with forest management on the Whiskey Jack Forest at this time.

Overlapping Licensees, Contractors and Commitment Holders

All businesses listed in the MNR District mailing list were sent the one-page KBM survey and letter soliciting input to the audit. Two of three commitment holders responded noting commitments were met in four of the five years. In 2008 commitments were not met due to circumstances beyond the control of the licensee. A meeting with Weyerhaeuser representatives took place during the audit. They expressed concerns that delays in the planning process and deficiencies in operational planning may negatively impact upon their ability to realize their commitments in the future.

SFL Holder

Interviews were held with the company's current planning forester and the former forestry superintendent. Information on the surrender agreement was also provided by SFL senior management. The current planning forester attended the site visit including portions of the field audit. Two senior managers participated in the opening meeting and one in the closing meeting via conference call. The audit team appreciates ACCC's efforts in supporting the audit process.

Ministry of Natural Resources

Interviews were held with Kenora District staff including the District Manager, Area Supervisor, Area Forester, Area Biologist, Area Technicians and Resource Liaison Specialist. MNR District personnel also accompanied the audit team in the field for one day including the Area Supervisor, Area Forester, and Area Technicians. The pre-audit meeting and audit opening and closing meetings were attended by MNR District personnel. The audit team appreciates the cooperation and assistance provided by MNR Kenora District staff in preparing the audit field packages and coordinating the field site visits.

One MNR Northwest Region representative participated in the pre-audit meeting and the closing meeting via teleconference.

Two representatives from MNR Forest Management Branch attended one field day and the Branch was also represented during the pre-audit meeting and closing meeting via teleconference.

Forestry Futures Trust Committee

One representative from the Forestry Futures Trust Committee participated in the pre-audit meeting via conference call, two representatives attended the opening meeting and one field day, and two representatives attended the closing meeting via teleconference.

Appendix 5 – List of Acronyms

ACCC	Abitibi-Consolidated Company of Canada
ACOP	Annual Compliance Operating Plan
AOC	Area of Concern
AR	Annual Report
AWS	Annual Work Schedule
Btk	Bacillus thuringiensis kurstaki
CEA(SFM)	Certified Environmental Auditor (Sustainable Forest Management)
CFSA	Crown Forest Sustainability Act
CP	Contingency Plan
CSA	Canadian Standards Association
EMS	Environmental Management System
EMS(LA)	Environmental Management System Lead Auditor
FFTC	Forestry Futures Trust Committee
FMP	Forest Management Plan
FMPM	Forest Management Planning Manual
FOIP	Forest Operations Information Program

Appendix 6 – Audit Team Members and Qualifications

Name/Role	Mr. Rod Seabrook • Lead Auditor • Public Consultation and Aboriginal Involvement
Responsibilities	Overall audit coordination and oversight of activities of the audit team; including public consultation and Aboriginal involvement in forest management planning; lead the assessment of achievement of management objectives, forest sustainability and contractual obligations
Credentials	M.Sc. Biology; CEA(SFM); EMS(LA); 29 years forestry experience in Ontario; principal area of practice is forest management and environmental auditing; accredited as a Certified Environmental Auditor (Sustainable Forest Management) by the Canadian Environmental Certification Approvals Board and as an Environmental Management System Lead Auditor by the Auditing Association of Canada; Associate member of the Ontario Professional Foresters Association; ten years of auditing experience; participated in 20 Independent Forest Audits for the Province of Ontario (seven as lead auditor; eight as lead and wildlife/ecology auditor; three as wildlife/ecology auditor; two as secretariat); IFA experience covers all Crown managed forest types in Ontario; conducted sustainable forest management audits under the various recognized sustainable forest management standards in Alberta, Saskatchewan, Manitoba, Ontario, New Brunswick, Minnesota, South Carolina, Georgia, Mississippi, Alabama, and Texas; participated in over 90 3rd party audits to the ISO 14001 EMS, CSA Z809, SFIS, FSC, and Chain of Custody standards.
Name/Role	Mr. Peter Higgelke • Wildlife/Ecology/Planning
Responsibilities	Inspect AOC documentation and practices; audit aspects of forest management related to environmental protection and wildlife practices; review access management program; review aspects of planning; assess achievement of management objectives, forest sustainability and contractual obligations
Credentials	R.P.F., M.Sc.F.; 29 years forestry experience in Ontario, Quebec, and Germany; served on one FMA Review and 16 IFAs, under a range of audit roles including Lead, Harvesting, Silviculture, Wildlife and Planning Auditor as well as auditing under FSC, including three forest management certification audits, three forest management scoping audits, six forest management surveillance audits and one chain-of-custody audit; completed ISO 14001 EMS Lead Auditor training through the Quality Management Institute in April 2006. Extensive knowledge and experience with wildlife and forest management as well as Aboriginal communities; interim plan author for the Lake Nipigon Forest 2010-20 FMP; primary areas of practice and disciplinary expertise are forest management, application development for the use of GIS technology in forest management, the integration of timber management and wildlife values, public participation in forest management planning, and participation by Aboriginal communities in forest management.
Name/Role	Mr. Laird Van Damme • Planning/Harvest
Responsibilities	Assess adherence to forest management planning requirements; assess compliance and monitoring programs; assess achievement of management objectives, forest sustainability and contractual obligations
Credentials	R.P.F., M.Sc.F.; 23 years experience as a practising forester, educator and consultant; primary areas of practice are in the disciplines of silviculture, forest management and forest research; completed ISO 14001 EMS Lead

	Auditor training course through the Quality Management Institute; served as a forestry auditor on 14 previous IFAs and several certification audits; Lead Auditor on two IFAs; led the Model Forest Program evaluation and the last National Forest Strategy evaluation; authored four FMPs and published numerous scientific and professional papers as an adjunct professor at Lakehead University; consultant to the government of Saskatchewan on forest management planning standards and landscape planning projects in Alberta; peer reviewer of forest management plans and certification audits.
Name/Role	Mr. Brad Chaulk • Silviculture
Responsibilities	Assess renewal and tending program; assess achievement of management objectives and forest sustainability.
Credentials	R.P.F., H.B.Sc.F.; 17 years of forestry experience; areas of particular experience include silvicultural practices and inventory systems including project management; diverse experiences as a tree plant supervisor, head of propagation and seedbed foreman at one of Ontario's largest nurseries, and as the supervisor and manager of technical services at KBM; member on 14 IFA teams; prepared pre- and post-harvest forest operating prescriptions and developed preferred harvest strategies, site preparation techniques, and planting/ tending regimes for individual harvest blocks; completed Managed Forest Tax Incentive Program plans for private landowners; conducted and written wood supply reports/timber analyses; considerable experience using the Forest Ecosite Classification systems for both Northwestern and Northeastern Ontario as well as the new Harmonized Ecosite Classification System for the Province; co-author Field Guide to Second Generation Progeny Test Establishment, Management and Assessment; plan author for the Black Sturgeon Forest 2006-2026 FMP; lead author of the Silvicultural Ground Rules for the Dog River-Matawin 2005-2025 FMP; project manager for both the Lake Nipigon Forest 2010-2020 FMP and the English River Forest 2009-2019 FMP; certified to interpret aerial photography in Ontario's Boreal Forest; teaches forest management planning at Confederation College.
Name/Role	Mr. Keith Hautala • Modeling
Responsibilities	Review SFMM strategic planning; assist in assessment of achievement of management objectives and forest sustainability.
Credentials	M.Sc.F.; 11 years of forestry experience in Ontario with an emphasis on long-term forest management planning, wildlife habitat analysis, strategic-level forest modeling, and forest auditing; participated in six IFAs in the position of Forest Modeling Auditor and an additional four as Secretariat; auditing responsibilities have included reviewing the assumptions, composition, and documentation of long-term strategic models, examining the development and evaluation of management alternatives, and assessing the achievement of management objectives and forest sustainability; teaches plant biology and wildlife courses at Confederation College.
Name/Role	Ms. Sonia Colombo • Audit Secretariat
Responsibilities	Provide general support in the execution of the IFA including logistics, evidence gathering, and report development.
Credentials	Dipl. For. Tech.; 20 years experience in forestry, focusing on forest renewal; established, and is in charge of, the Seedling Assessment Lab at KBM Forestry Consultants Inc. conducting third-party stock quality testing for private nurseries and forest companies; Administrative Assistant on three Independent Forest Audits; completed ISO 14001:2004 Lead Auditor training; participated in two ISO 14001:2004 audits as a provisional auditor.

Appendix 7 – Comparison and Trend Analysis Report

February 16, 2007

DRAFT
Hardwood Sources for I-Level (Weyco) composite mill

Discussion of alternatives to sourcing from the Whiskey Jack Forest…

Research Question: Are there alternate sources of hardwood supply for the Kenora I-Level Timberstrand composite mill, other than the Whiskey Jack Forest?

Synopsis

A cursory examination of the latest provincial data available reveal that there exist substantial volumes of available hardwood within economically viable trucking distances of Kenora Ontario, and outside the Whiskey Jack Forest (WJ). While annually the Kenora I-Level mill sources 160,000 m3 of hardwood from the WJ, other forests in Northwestern Ontario have over 800,000 m3 of hardwood available in the long or short term. Forests in Eastern Manitoba have an additional 350,000 m3 of hardwood available on a long term basis. These more than ample alternate supplies, combined with low demand for Timberstrand product and the existence of alternate production sites, demonstrate that it is fully possible to implement a moratorium on logging in the Whiskey Jack Forest without impacting the wood supply for the Kenora I-Level mill.

Whiskey Jack Supply

The Weyerheuser I-Level mill product is produced by cutting low-grade species (mostly aspen) into thin strips and bonding them together under high pressure and temperature. This means that log quality is not paramount, and supply specifications can be broad. Birch is also used by the plant, providing additional flexibility.

Despite several explicit attempts to obtain more recent data, the most recent Annual Report data available for the Whiskey Jack forest is for the 2003-04 year. Given that MNR has provided this twice when asked for 2004-05 data, it is perhaps likely that they have not received anything more current from Abitibi.

The data on Manitoba forests was taken from the province's "Five Year Report on the Status of Forestry; April 1996- March 2001." The numbers used in this document are average m3 per year for the five year period. Annual volumes did not vary substantially over this period.

Footnote:
http://www.gov.mb.ca/conservation/forestry/reports/fiveyear02_eng.html

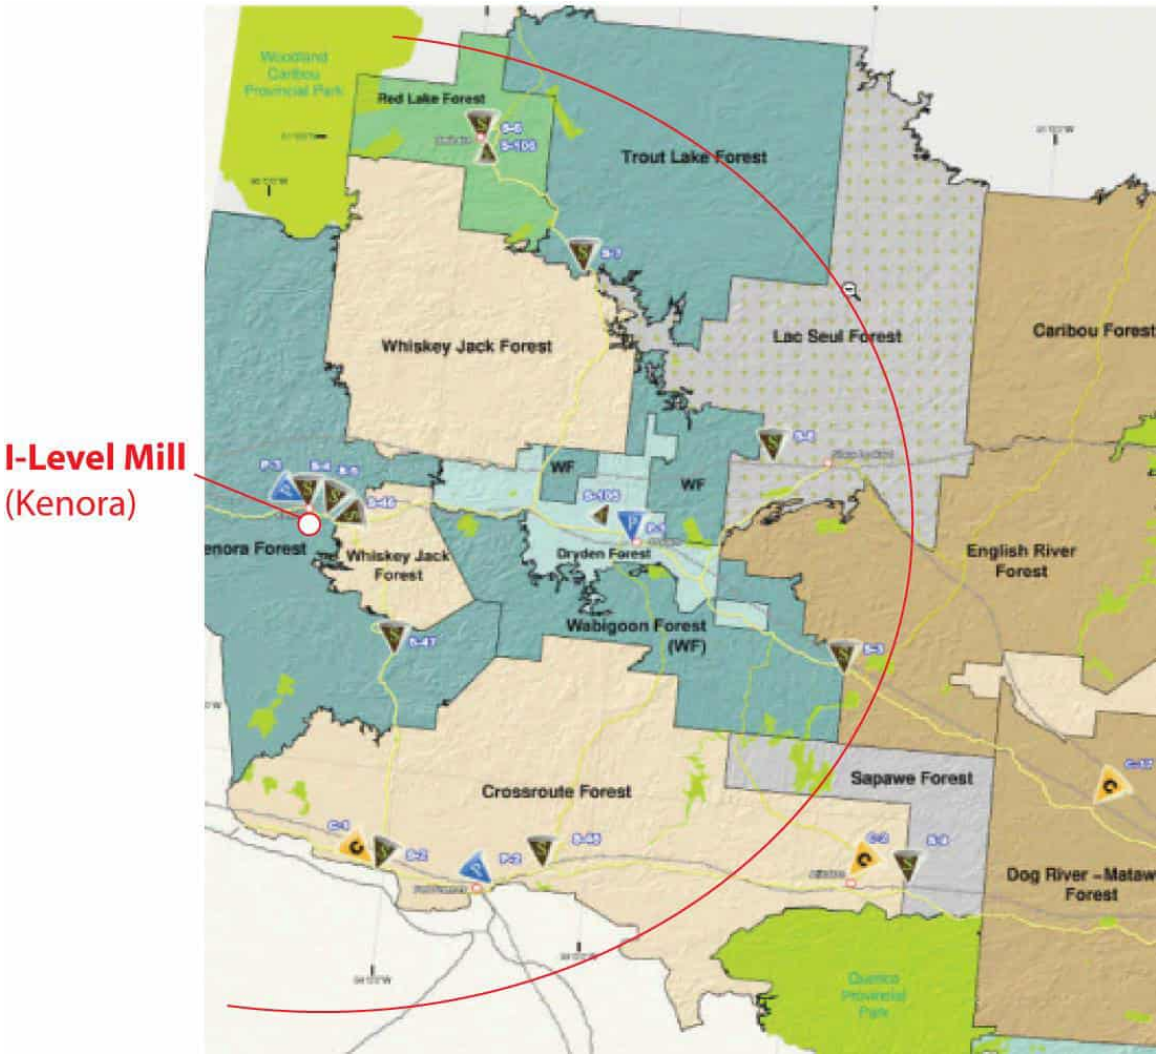
Available supply was found in Table B12: Net Merchantable Annual Allowable Harvest Summary by Forest Management Unit/Section and Species Provincial Crown Land.
Utilization rate was found in Table B13: Annual Forest Product Harvest 1996-2001

156,188 m^3 of Poplar was sourced by this mill from the Whiskey Jack forest in 2003-04 (MNR records, AR-5 data). Because the mill is so new, preliminary figures cannot be used to create any kind of longer term trend or more accurate average as the mill was gearing up production. And as already mentioned, more recent years do not seem to be available. A rounded figure of **160,000 m^3 will be used as the supply to be replaced.**

Alternative Sources

1) Current I-Level reduction in capacity
Due to current market conditions, a significant reduction in mill production is being experienced and is likely to persist for an extended period of time. Weyerhaeuser indicates that the mill is running below 1/3 capacity. This translates into a short-term reduction in feedstock required over the short-term. **[106,000 m^3 – short-mid term]**

2) Shift production to other iLevel Timberstrand mills
Weyerhaeuser has two mills outside Kenora that make the same iLevel Timberstrand product, one in Deerwood MN, and one in Chavies, KY. The company could shift production to those mills to reduce fiber needs in Kenora.



3) Re-allocate unused available hardwood supplies from NW Ontario FMU's

(a) Kenora Forest (Weyerhaeuser tenure) – in 2004-05, the I-Level mill only utilized 48,000 m^3 of a forecasted 125,000 m^3 hardwood harvest, leaving a potential 77,000 m^3 of supply available. **[77,000 m^3 long term]**

(b) Wabigoon Forest (Weyerhaeuser tenure) – in 2004-05, 217,000 m^3 of hardwood was harvested from this Weyerheuser tenure, including some directed to the I-Level facility. 180,000 m3 of this harvest went to the Weyerheuser Dryden Paper operation, which has since idled. This facility is currently only producing kraft pulp. Weyerheuser could increase volumes already destined for I-Level up to the volume used by Dryden's paper mills until such time as they come back online. [**180,000 m^3** short-long term]

(c) Dryden Forest (Independent tenure) – in 2004-05, 63,000m3 of hardwood was forecast for harvesting from the Dryden forest. None of the

destinations used this volume in that year, except for some personal fuel use. 48,000m3 was destined for the idled Dryden paper operation. 12,000 m3 was destined for the closed Dryden sawmill, and 2,000 to the closed Abitibi mill in Kenora (both long-term options). [**62,000m3 long term**]

(d) Crossroute Forest (Abitibi tenure) – in 2004-05, the FibraTech composite mill used 17,000 m^3 less hardwood than forecasted, the Manitou sawmill used 97,000 m^3 less, and an unspecified forecast destination did not report use of its 19,000 m^3 (these last two may represent long-term options). [**133,000 m^3** mostly long term]

(e) English River Forest (Bowater tenure) – in 2004-05, 189,000 $m^3$of a forecast 340,000 m^3 of hardwood was harvested. The now closed Buchanan Northern Hardwood sawmill only harvested 45,000 m^3 of a forecasted 97,000 m^3 (this may represent a long-term option). Both the Weyco Dryden and Bowater Thunder Bay Pulp and Paper mills source hardwood from this unit, and both have indefinitely idled machines, making up the bulk of the rest of the hardwood harvest (another significant short-term option). [**97,000 m^3** long term] and [+/- **200,000 m^3**]

(f) Sapawe Forest (Buchanan tenure) – in 2004-05, the FibraTech composite mill only utilized 28,000 m^3 of a forecast 77,000 m^3, leaving a possible 49,000 m^3 available. [**49,000 m^3**]

Over **800,000 m3 of alternative sourcing** has been identified above for the mill from a cursory examination of the hardwood usage in this particular woodshed during the 2004-05 period. Trends towards even lower levels of hardwood usage could be reasonably expected since this benchmark, though probably combined with a general reduced harvest across most areas. The forests identified here are largely non-intact, outside prime caribou range, and free of high profile First Nations controversies. In some areas, including Weyerhaeuser's Wabigoon forest, Weyerhaeuser has established agreements with local First Nations.

4) Re-allocate unused available hardwood from Eastern Manitoba

(a) Pineland forest - from 1996-2001, the allowable annual harvest of merchantable hardwood in the "open zone" of this forest was 218,000 m3. The actual average annual harvest was 76,000 m3, leaving 142,000 m3 available. This entire forest area is within economically viable trucking distance of Kenora via highway 17. **[142,000 – long-term]**

(b) Lake Winnipeg East forest - from 1996-2001, the allowable annual harvest of merchantable hardwood in the "open zone" of this forest was 327,000 m3. The actual average annual harvest was 12,000 m3,

leaving 315,000 m3 available. We estimate that the southern half of this forest area is safely within viable trucking distance, and outside the largely intact east side of Lake Winnipeg. Much of this area is within Tembec's FML-1. Tembec is a company that has committed to 100% FSC certification, so this likely represents a current or future FSC certified supply. **[157,500 m3 – long-term]**

(c) Aspen Parkland forest - from 1996-2001, the allowable annual harvest of merchantable hardwood in the "open zone" of this forest was 116,000 m3. The actual average annual harvest was 2,000 m3, leaving 114,000 m3 available. We estimate that the eastern half of this forest area is safely within viable trucking distance. **[57,000 m3 – long-term]**

Over **350,000 m3 of viable, long-term, alternative sourcing** has been identified for the above mill from a cursory examination of hardwood usage in Eastern Manitoba during the 1996-2001 period. 20% of Weyerhaeuser's current supply for the mill originates in Manitoba, so clearly the border does not represent a barrier, with highway 17 providing a prime conduit. Overall, Manitoba had 2,622,000 m3 annually of unused and available merchantable hardwood supply. This dramatic oversupply, combined with the fact that Manitoba's top user of hardwood (the Swan Lake mill) is in the distant northwestern part of the province, make it unlikely that this available supply will decline. We therefore assess this to be a long-term supply option.

Conclusion

There are viable hardwood supply alternatives for the I-Level mill to source from, outside the Whiskey Jack forest. Hardwood is not a scarce commodity in NW Ontario at this time. In fact, a provincial committee has been struck to address the problems associated with widespread underutilization of hardwood in the Province. The I-Level mill has historical supply links to several other forests other than the Whiskey Jack forest which it has not always fully utilized. Other historical hardwood users in the region are either closed or idled currently. In addition, the annual volume of viable hardwood available long-term in Eastern Manitoba alone is more than twice the volume sourced from the Whiskey Jack forest in 2004-5. In total, the volume available from the alternate sources outlined here, is greater than seven times the volume currently sourced from the Whiskey Jack Forest. The areas examined are mostly free of high profile First Nations conflicts, and mostly outside of ecological priority areas. The combination of low market demand, alternative production sites, and substantial alternate supplies in Northwestern Ontario and Eastern Manitoba demonstrate that it is fully possible to implement a moratorium on hardwood logging in the Whiskey Jack without substantively impacting the Weyerhaeuser iLevel Timberstrand mill in Kenora.

INTRODUCTION

In the 1960's, the Asubpeeschoseewagong Netum Anishinabek (ANA, Grassy Narrows First Nation] experienced one of the worst disasters in Canadian history. The community's livelihood, major food source and health were destroyed by the dumping of massive amounts of mercury into their waterways. Fifty years later, concerned by the continuing ill health and conditions in their community, ANA undertook a Community Health Assessment (ANA-CHA) to better understand the health and wellness of ANA adults and children. This community-driven endeavour sought and obtained financial support from Health Canada and the Ontario Ministry of Health and Long-Term Care. Technical assistance was provided by these ministries as well as the Ontario Agency for Health Protection and Promotion, the Ontario Ministry of Indigenous Relations and Reconciliation, and the Northwestern Health Unit of Ontario.

The parties established a Community Health Assessment Team (CHAT) and in September 2016 signed a project Charter that laid out the overall goals, responsibilities of the parties, activities to be carried out and a time line. The Charter endorsed the OCAP® principles of Ownership, Control, Access and Possession of knowledge and information by the First Nation[1].

The objectives of the CHA as stated in the Charter are:

"The overall goal of this project is to provide a better understanding of the health status and its determinants among ANA members; this will serve a number of additional key objectives, including:

- *Support planning of health services for ANA members;*
- *Understand the determinants of health unique to ANA members;*
- *May, along with other research, contribute to scientific knowledge on the impact of mercury contamination; and*
- *May be considered in proposing changes to the Mercury Disability Board."*

In keeping with these goals, the CHA used the First National Regional Health

[1] http://fnigc.ca/ocap.html

Survey Report (2008/2010)[2] (FNRHS Canada) as the basic framework for the survey, adding on the further dimension of the environment, and specifically mercury. Figure 1 shows our schematic model adapted from the FNRHS Report[3]. Our framework includes the natural environment, which affects all of the dimensions of health and wellness. For example, the natural environment can provide food, income, influence behaviours and constitute a place for physical and spiritual activities. Damage to the environment can affect health and wellness directly and indirectly. For example, environmental damage from dumping mercury into the river system or from logging can affect food security, the availability of nutritious foods, personal and community wellness, as well as physical and mental health and chronic disease.

This approach allowed us to i) compare the results of ANA Band members on reserve to other First Nation communities in Canada and Ontario[4], and ii) examine how consumption of mercury-contaminated fish may have contributed to health and wellness. The survey, administered between December 2016 and March 2017,

EXECUTIVE SUMMARY

This Community Health Assessment (CHA) stems from a request by the Asubpeeschoseewagong Netum Anishinabek (ANA, Grassy Narrows First Nation) to better understand the health and wellbeing of their community and its determinants. In addition to suffering the plight of many First Nation communities in Canada through relocation, residential schools, colonialism and cultural genocide, poverty, poor access to health care, food and potable water, since the 1960's, mercury contamination of ANA's waters and fish has impacted community members' livelihood, nutritious food sources, and health. The ANA-CHA sought to address these issues in adults and children with a view to improving health and wellbeing of the ANA community.

The overall findings of the Adult ANA-CHA survey show that the health and wellbeing of ANA Band members cannot be understood without taking into account their history of mercury poisoning.

The statistical analyses indicate:

- For the most part, the physical and mental health of the ANA community is considerably worse than that of other First Nations in Ontario and in Canada.
- Mercury exposure, through consumption of contaminated fish, is associated with poor health and well-being.
- This situation has important consequences for the economic and social prosperity of individuals and the community
- Current programs are inadequate in addressing many of these issues.

The results of the survey likewise show that despite their physical and mental health challenges, ANA community members endeavour to maintain and improve their health and wellbeing both individually and collectively.

Below is a summary of the key findings of each chapter:

Chapter 1. Methods: The CHA used a computer-based survey questionnaire, adapted from the First Nations Regional Health Survey (2008/2010) (FNRHS)[5], to which specific questions on mercury exposure and effects were added. This allowed us to identify similarities and differences with other First Nation communities in Canada and in Ontario[6], and to examine the possible impacts of mercury exposure. Since the FNRHS was carried out with Band members living on reserve, all comparisons were limited to ANA Band members on reserve. For mercury-related outcomes, all Band members were included in the analyses.

The field ANA team, led by a coordinator and an assistant coordinator, designed the recruitment strategy, carried out the recruitment, and administered and uploaded the questionnaires. Between December 2016 and March 2017, nine ANA surveyors visited 178 (83.6%) of the houses in Grassy Narrows; 322 adults (78.2%) participated in the survey. A further 101 adults living off reserve were also surveyed. The population analyzed in the present report includes 421 adults, of whom 387 (77%) are Band members and 34 are spouses of Band members or living in Grassy Narrows. The age and sex distributions of ANA-CHA participants are similar to ANA's distributions in the Statistics Canada Aboriginal People's Household Survey 2016, indicating that **the sample is representative of the underlying population.**

Statistical analyses included descriptive statistics, group comparisons, multivariate and multidimensional to explore the complex associations between benefits, risks and outcomes.

Chapter 2. Demographics: Participants' mean age is 38 years of age, ranging from 18 to 80. The **age pyramid** provides important information on a community's development. Similar to other surveys of ANA, the CHA reveals that among ANA Band members on reserve, there are **proportionally fewer elders** and proportionally more children. This not only reflects **premature death**, but also that there are **fewer elders to transmit traditional knowledge and guidance** to the younger generations.

Chapter 3. Mercury exposure: Fish consumption is the route for mercury exposure in Grassy Narrows. The ANA-CHA adult questionnaire contained several questions that sought to estimate mercury exposure through fish consumption over time. Since prenatal and childhood mercury exposure may contribute later-life health, several questions sought to estimate early life exposure for each participant:

[5] First Nations Information Governance Centre (FNIGC) (2012). First Nations Regional Health Survey (RHS) 2008/10: National report on adults, youth and children living in First Nations communities. Ottawa: FNIGC. (FNRHS, Canada)

[6] First Nations Regional Health Survey (RHS) Phase 2 (2008/2010) Ontario Regional Final Report. First Nations Information Governance Centre (FNIGC). Chiefs of Ontario, 2012. (FNRHS Ontario)

(i) mother's residence during pregnancy; (ii) whether their father was a fishing guide; (iii) the person's fish consumption at 10 years of age. A further question asked about current consumption of walleye and northern pike.

The major source of mercury contamination in Grassy Narrows is from a chlor-alkali chemical plant in Dryden. It began in 1962 and the first measures of human exposure (hair, blood and umbilical cord blood) were made in 1970[7]. We were able to validate the responses about mercury exposure through fish consumption using umbilical cord mercury data for 58 persons between the ages of 26 and 46 years (born between 1970 and 1990), provided by Health Canada. **Persons who answered that their father was a fishing guide and that they themselves consumed fish several times a week or more at age 10 had an average of four times the amount of mercury in their umbilical cord blood compared to those who answered no to both questions.**

Sediment core analysis has shown that total mercury concentration increased abruptly just after 1961, peaked around 1968 at a value approximately 100 times the background level, declined slightly until around 1974, and then dropped rapidly until 1986, whereupon it tailed off gradually but remained an order of magnitude higher than the pre-pollution background level[8] . The changes in mercury exposure and in fish consumption behaviour over time have methodological implications for the statistical analyses in the present report. Age is positively correlated with having a father who worked as a fishing guide and the person's fish eating practices - the proportion of persons who ate fish at least several times a week when he/she was 10 years of age increases with age. Overall, older persons had higher exposures. **To take this change over time into account, all analyses, which include fish-eating variables, are age-adjusted.**

There are still high concentrations of mercury in fish on the Grassy Narrows territory; the highest levels are in walleye and northern pike. A third of ANA Band members report that they often ate walleye over the past year.

Chapter 4. Residential school, education and training: Twice as many Band members from Grassy Narrows (15%) attended residential schools compared to other First Nation communities in Ontario (8%). **For Band members over 60 years of age, 88% were placed in residential schools, almost twice as many as other First Nation communities in Canada (46%).** Among those who had been to residential school, 69% indicated that it negatively impacted their health and

[7] Wheatley B et al. Exposure patterns and long term sequelae on adults and children in two Canadian indigenous communities exposed to methylmercury. Water, Air and Soil Pollution 97: 63-73; 1997.

wellbeing. Over 60% of adult Band members have a least one parent who had been placed in a residential school.

Over 70% of ANA-CHA participants less than 50 years of age have at least some high school and around 20% have a high school diploma. Almost half of all participants (48%) indicate that they had further education, such as trade, technical or vocational school. **School achievement** is an important determinant of later-life health, wellbeing and success. Participants in the ANA-CHA are no exception: taking into account age and sex, **school success is positively associated with:** further education, income, good health, a nutritious diet, a sense of belonging to the community, mastery score ("the extent to which an individual regards their life chances as being under their personal control rather than fatalistically ruled"[9]), having a good social support network and taking part in the community's cultural events.

For those under 50 years of age, we examined the **factors associated with school success**: success in school decreased with age (younger adults report lower school success); women did better than men; those who had been to a residential school reported less success; **school success was lower among those who consumed fish at least several times a week when they were 10 years of age compared to those who consumed less fish.** The latter finding suggests that mercury exposure from fish consumption contributes to poor success in school. Poorer neurodevelopment has been associated with prenatal exposure to mercury in many studies, including in Inuit communities in Canada.[10]

Chapter 5. Work and income: A total of 43% of ANA CHA participants report paid employment. For ANA Band members on reserve, the percentage is 46%, similar to First Nation communities in Canada (47%), but less than other First Nation communities in Ontario (55%). For those who are not working, 41% report that it is due to a health problem or disability. This is twice as high as other First Nations in Ontario and in Canada (20%). Persons who have been told by a health professional that they have mercury poisoning have the highest rate for not working due to health problems or disability (67%).

Approximately **50% of participants report income of less than $20,000 per year and 33% report income of less than $10,000.** Individual and estimated household incomes are positively associated with currently working, school success, while individual income is also associated with good health. Individual and estimated household incomes are lower among those who have been told by a

[9] Pearlin, L. I., & Schooler, C. (1978). The structure of coping. Journal of health and social behavior, 2-21.

[10] Jacobson et al. Relation of prenatal methylmercury exposure from environmental sources to childhood IQ. Environmental Health Perspectives 123:827-833; 2015.

health professional that they have mercury poisoning and persons who receive disability.

Chapter 6. Health status: Self-rated health perception is a measure that is commonly used in First Nation and Canadian surveys. Considerably **fewer ANA Band members (21%) rate their health as very good or excellent, called thriving, compared to other First Nations in Ontario (40%) and First Nations in Canada (44%) and the Canadian non-Indigenous population (60%)**. The proportion of persons who report poor health increases with age and more quickly in women compared to men.

In the ANA-CHA, we used the FNRHS list of ***chronic health problems*** informed by a health professional, which does not include mercury poisoning or neurologic disorders. Sixty-seven (67%) of ANA-CHA participants report that a health professional has told them that they have at least one of the chronic health problems on the list. A higher percentage of women report at least one of these chronic health problems compared to men (73% vs. 60%). In both men and women, the percentage of those reporting at least one diagnosed chronic health condition increases with age. In comparison to First Nation communities in Canada, proportionally more Band members on reserve, under 50 years of age, report at least one chronic health condition. For those 50 years and more the percentage is similar. The largest difference is for persons 40 – 49 years of age (83% vs. 66%).

The FNRHS included several neuropsychological conditions, such as learning disabilities and Attention Deficit/Attention Deficit-Hyperactivity Disorder (ADD/ADHD), cognitive or mental disabilities and psychological or nervous disorders, several of which were added to the ANA-CHA. A total of 53 Band members (14%) report that a health professional had told them that they have at least one of these neuropsychological disorders.

The FNRHS did not include **chronic neurologic conditions**, which were included in the ANA-CHA. A total of 21 Band members report that they have been told by a health professional that they have a neurologic disorder, the most frequently mentioned is Bell's palsy. We combined neuropsychological and neurological disorders, called **nervous system disorders,** which groups persons who have been told by a health professional that they have at least one of the neuropsychological or neurologic health conditions listed in the ANA CHA questionnaire. Twenty-four percent (n = 88) of Band members answered that they had at least one of these conditions.

***Co-morbidity* of 4 chronic health conditions** from the FNRHS list is compared between First Nations in Canada and ANA. While there is no overall difference for men, a large difference is observed for women (27% vs. 13%). Moreover, **the**

differences increase with age, with a higher percentage of ANA Band members reporting 4 or more chronic health conditions: for ANA it is 7% for those under 30 years of age to 69% for those over 60 years of age, compared to 3% to 47% for the same age ranges for First Nations in Canada.

The most frequently ***chronic health conditions*** reported in the ANA CHA survey are: allergies (30%), high blood pressure (27%), nervous system disorders (23%) and diabetes (21%). With the exception of asthma, specific chronic health conditions increase with age and many are more prevalent in women compared to men. The prevalence of many health conditions among ANA Band members on reserve and First Nations in Ontario and Canada are similar, but **ANA Band members on reserve report a higher prevalence of the following chronic health conditions: allergies, stomach and intestinal problems, blindness or visual problems not corrected by glasses, hearing impairment, rheumatism (joint pain), psychological or nervous disorder and tuberculosis.** The prevalence of **diabetes** among ANA Band members on reserve is higher than in other First Nation communities in Canada, but similar to Ontario. Nervous system disorders were not included in the First Nations regional health surveys.

It is noteworthy that the prevalence of persons reporting that a professional has told them that they have ***heart disease*** is considerably lower among ANA Band members than other First Nation communities in Ontario and Canada. For those over 60 years of age, it is 3 times lower than in Ontario (9% vs. 29%). This needs to be examined more closely and better understood since several studies have reported an association between myocardial infarction and mercury exposure.

Body mass index (BMI) was calculated (weight/height^2) in kg/m^2. We used the Canadian Guidelines for Body Weight Classification in Adults for classification. Forty-one percent (41%) of men and 54% of women are classified as 'obese' (equal to or greater than 30 kg/m^2), with 5% of men and 10% of women in the Obese Class III category (equal to or greater than 40 kg/m^2), which is associated with an extremely high risk of developing health problems. **The BMI distribution is similar to other First Nation communities.** In the analyses, we use equal to or greater than 30 kg/m^2, as the cut-off for obesity. Diabetes and high blood pressure are associated with obesity in both men and women, but there are gender differences for other factors. More women who are obese have thoughts about suicide compared to women who are not. For men, high cholesterol is associated with obesity, while more men who report nervous system disorders are not obese. Fewer men who smoke or who are heavy drinkers are obese compared to those who do not smoke or are not heavy drinkers.

We examined the possible association of different factors with the specific chronic health conditions, using multiple regression analyses. When there were too few

persons under 30 years of age with the condition, we only included persons 30 years and more. Most associations were as expected. Noteworthy is the association between asthma and struggling to pay for utilities, which may represent poorly heated homes. For diabetes, in addition to the expected associations with age, high cholesterol and body mass index, **persons who had consumed fish more than several times a week when at ten years of age were 2.5 times more likely to have been told by a health professional that they have diabetes.** The likelihood for **nervous system disorders is twice as high for those whose father was a fishing guide and for those who ate fish several times a week when they were 10 years old, taking into account age and drinking habits.** It is noteworthy that proportionally fewer persons who report nervous system disorders are current heavy drinkers.

Chapter 7. Diabetes: consequences and care: Diabetes is a major health concern in many First Nation communities and among the CHA-ANA participants one person in five reports that a health professional has told them that they have diabetes. The median age for diagnosis was 38.5 years, with the youngest diagnosis at 10 years of age and the oldest at 65 years of age.

When compared to other First Nation communities, **more ANA Band members on reserve with diabetes are attending a diabetics clinic or seeing someone** (doctor, nurse, etc.) (ANA: 72% vs. Other First Nations: 53%). However, fewer are undergoing treatment (ANA: 79% vs. other FN: 90%). Moreover, the proportions for the type of treatment differs significantly: in ANA, proportionally fewer persons treat their diabetes with diet (41% vs. 66%) or exercise (25% vs. 50%) and **proportionally more are being treated with insulin (36% vs. 20%).**

The pattern of diabetic co-morbidity is likewise different: in **ANA proportionally more persons respond that diabetes has affected feeling in their hands and feet (61% vs. 34%), vision (48% vs. 36%), circulation (44% vs. 29%), lower limbs (35% vs. 23%) and resulted in infections (25% vs. 15%),** while there is no difference in the proportion of those who report that their kidney function has been affected (23% vs. 21%). It is noteworthy that the symptoms reported in a higher frequency by ANA Band members with diabetes are also associated with mercury exposure.

The differences in diabetes consequences and care between ANA and other First Nation communities need to be better understood since mercury exposure may contribute to or aggravate diabetes and/or diabetic co-morbidity.

Chapter 8. Mercury poisoning: Several questions on the ANA CHA survey focused on mercury poisoning, including having been previously examined by Dr. Masuzumi Harada's team from Japan, being told by a health professional that you have

mercury poisoning, symptoms of mercury poisoning and claims to the Mercury Disability Board.

A total of 388 ANA Band members answered the question on previous examinations by the Japanese doctors: 56 (14%) were examined once, 31 (8%) were examined more than once and 17 (4%) did not know. Since the first visit by these doctors was in 1975, those who had been examined are significantly older than the others. Harada notes in his 2002/2004 report that all of the persons who had hair mercury concentrations above 50 ppm were deceased[11]. Fifty-seven percent (57%) of persons over 50 years of age had been examined at least once by the Japanese doctors. Most did not remember the diagnosis.

In answer to the question on whether a health professional had told you that you have **mercury poisoning, 60 Band members** responded 'yes', and 125 answered that they did not know (32%). The proportion of those who answered that they did not know is very high compared to the other questions on chronic health conditions, where the percentage of those who responded that that did not know was between 2% and 12%. This may reflect reluctance to answer 'yes' among persons that are experiencing known symptoms of mercury poisoning. Indeed, persons who answered that they didn't know reported significantly more symptoms than persons who answer no, but fewer symptoms compared to those who answered 'yes'.

When considering only persons who answered 'yes' or 'no' to the question, over one out of 5 Band members (23%) responded in the affirmative. There is no difference between the percentage of men and women. **Over 50% of persons over 50 years of age have been told by a health professional that they have mercury poisoning.** More Band members with mercury poisoning (n = 50 (83%)) live on reserve, while 10 (17%) live off reserve. All of the men (n = 28) with mercury poisoning are on reserve; the 10 persons off reserve with mercury poisoning are women.

The likelihood of being told that you have mercury poisoning is almost 5 times higher for those whose father had been a fishing guide, taking into account age and sex. For those under 50 years of age, it was three and half times higher, taking into account age and sex.

Co-morbidity with mercury poisoning is high: **Over half (55%) of those that have been told that they have mercury poisoning report at least four other chronic health conditions, compared to 12% among those who have not been told that**

[11] Masazumi Harada et al. Long-term study on the effects of mercury contamination on two indigenous communities in Canada (1975-2004)". Report in 2005 Translation by Tadashi Orui, proofread by Thor Aitkenhead.

they have mercury poisoning. When adjusted for age and sex, those who have been told that they have mercury poisoning are 4.5 times more likely to have four or more other chronic health conditions. The likelihoods for the specific chronic health conditions are: allergies (5 times), at least one neuropsychological disorder (5 times), blindness or vision problems that are not corrected by glasses (3 times), stomach and intestinal problems (4 times). For those over 30 years of age: hearing impairment (4 times), high cholesterol (4 times), and rheumatism (joint pain) (4 times), chronic back pain (2 times).

There are proportionally more persons who have been told by a health professional that they have **mercury poisoning** who are **not working** (61% vs. 43%) and they constitute 65% of those who indicate that they are not working **because of poor health or they are disabled**. They have **lower incomes** both individually ($p<0.05$) and by household ($p<0.05$).

It is well-established in the scientific literature that mercury poisoning is on a continuum of dysfunction with initial manifestations involving an increase in mercury-related symptoms and the final stages, a debilitating neurologic disorder and death. In the ANA-CHA, we included a list of 58 symptoms that reflect diminished well-being. Participants responded on a 5-point frequency scale from never to all of the time.

Because of the difference in exposure profile over time and the small number of elders that ate less fish when they were young, we included only persons less than 50 years of age in most of the analyses of symptom reporting. Most adults under 50 years of age were exposed to mercury *in utero.* The placenta actively concentrates mercury and the concentration of mercury in the umbilical cord blood is on average approximately twice that of the mother's blood.[12] For this age group, we analyzed symptom reporting with respect to age, sex, obesity, heavy drinking, having at least one chronic health condition, and fish consumption at 10 years of age for persons.

For women, age and at least one chronic health condition are the major factors associated with most symptoms, while fish consumption at 10 years of age is associated with 18 symptoms. For men, almost all symptoms are associated with fish eating at 10 years of age. **The strongest associations with childhood fish consumption for both women and men are symptoms of peripheral neuropathy.**

---

12 Mergler D, Anderson HA, Chan LH, Mahaffey KR, Murray M, Sakamoto M, Stern AH. (2007) Panel on Health Risks and Toxicological Effects of Methylmercury. Methylmercury exposure and health effects in humans: a worldwide concern. Ambio. 36:3-311.

Since symptoms are often inter-correlated, we carried out analyses that grouped the symptoms into 6 clusters. We examined whether these cluster of symptoms were associated with childhood and current fish eating, taking into account the other factors that were associated with the cluster, such as age, sex, having at least one chronic illness or diabetes, smoking, drinking, nutrition, mother or parent in a residential school and income adequacy. The results show the following:

Childhood fish consumption is associated with:

- Cluster of symptoms of peripheral neuropathy
- Cluster of symptoms of sensory and sensory-motor loss
- Cluster of symptoms of neuropsychological deficits
- Cluster of symptoms of motor loss and tingling around mouth
- Cluster of symptoms of loss of hearing, vision and speech

Current fish consumption is associated with:

- Cluster of symptoms of peripheral neuropathy
- Cluster of symptoms of sensory and sensory-motor loss
- Cluster of symptoms of motor loss and tingling around mouth

Finally, the analyses were rerun without those who have been told by a professional that they have mercury poisoning (n = 30). There is no difference in the associations between the factors listed above and the dimension outcomes, indicating that even those without diagnosed mercury poisoning, show an increase in the score of most symptom clusters with childhood fish consumption and for some symptom clusters, with eating walleye over the past year.

A total of 95 ANA members report that that they have made a claim to the Mercury Disability Board. Of them, 21 (22%) indicate that their claim was accepted, 11% that their claim is in progress, and 67% report that their claim was refused. **Those who have made a claim have significantly higher total scores for the above clusters compared to those who have not made a claim, but the scores are similar for those who were accepted or refused, independently of age, sex and diabetes.**

Chapter 9. Individual wellness and mental health: The ANA-CHA assessed different dimensions of personal wellness and mental health: i) within the community; ii) outside of the community; iii) mental and emotional health; and (iv) suicide.

- **For personal wellness within the community**, the survey included questions on the sense of belonging to the community and social support, a measure of whether one has people they can talk to about their emotional or mental health.

- 66% of Band members on and off reserve report that their ***sense of belonging to the community*** is somewhat or very important. This sense of belonging is highly correlated to being part of a social network.

- Women have a higher ***social support*** score compared to men. Women talk more to others about their emotional and mental health; the immediate family and friends are particularly important. The social support score is higher among those with a greater sense of belonging to the community, greater mastery over what happens to them, higher income, and for women, with more education, currently working and having children, and lower among those who smoke, are heavy drinkers and use cannabis. It is lower among those who have thought about or attempted suicide.

- For personal wellness outside of the community, the survey addressed some of the issues of ***racism***.

  - **Almost one half of participants (45%) report experiencing racism over the past 12 months**. The percentage is higher for Band members who live off reserve (60%). Among those who experienced racism, 42% indicate that it had at least some effect and 16% answered that it had a strong or very strong effect on their self-esteem.

  - Persons whose self-esteem is affected by racism have higher psychological distress, see themselves as having lower control over what happens to them, and report less social support.

  - Proportionally more ANA Band members on reserve report instances of racism over the past 12 months compared to other First Nations in Ontario and Canada and 48% indicate that it had some or a strong effect on their self-esteem compared to approximately 30% of First Nations in Ontario and Canada.

  - **Over one third of persons who report instances of racism over the past 12 months likewise report that feeling uncomfortable because of racism constituted a barrier to accessing health care (n=56).**

- **Mental and emotional health.** The ANA-CHA used validated questionnaires to assess (i) Mastery: the extent to which an individual regards their life chances as being under their personal control rather than

fatalistically ruled. (ii) Psychological Distress: Questions likewise addressed suicidal ideation and attempted suicide.

- The ***Mastery Score*** is higher among those with more education, those who currently work, those who are food secure, those who eat nutritious meals, non-smokers, those whose health is thriving, and those for whom belonging to the community is important. It is lower for those who struggle to pay their bills, those who are food insecure and those for who racist experiences affect their self-esteem, and heavy drinkers. The average mastery score among ANA Band members on reserve is similar to that of other First Nation communities in Canada.

- ***Psychological distress*** is categorized as low, moderate and high. More men report low psychological distress (47%) compared to women (33%), and more women (21%) report high psychological distress compared to men (9%). Social support is a major protective factor for psychological distress, while food insecurity is a risk factor. The risk for psychological distress is higher among those who suffer from at least one chronic health condition and nervous system disorders. **The proportion of women Band members on reserve who report high psychological distress is almost 3 times higher compared to First Nations in the rest of Canada (21% vs. 8%) and twice as high for men (11% vs. 5%).**

- **Suicide:** Suicide is an important challenge in many First Nation communities. Suicidal behaviour includes not only attempted suicide and fatal suicide, but also ideas and thoughts about suicide that are never acted on. **Among ANA-CHA participants, one third (34%) report that a close friend or family member has died of suicide; 137 persons (37%) have thought about committing suicide;** more women (42%) than men (31%) and more younger people (18-29 years of age (45%), compared to those over 50 years of age (26%). Of these, a total of 50% thought about committing suicide as an adolescent and 30% thought about it during the past year.

  A total of 132 persons (96%) of those who have had suicidal thoughts reported on suicide attempts. Of these, 103 (78%) have attempted suicide, constituting 28% of all participants who answered the questions on suicide. The prevalence of attempted suicide is higher among women (34% vs. 22%). Among the 101 persons who answered the question about when in their lifetime did the suicide attempt occur: 43 persons (42%) answered that it was during adolescence (12 – 17 years of age) and **21 persons (22%) answered that it was during the past year.**

All of these percentages are considerably higher than what is reported for other First Nation communities in Ontario and in Canada.

	ANA on reserve	FN in Ontario	FN in Canada
Close friend or family member died of suicide	**32%**	**7%**	**12%**
Suicidal ideation	**37%**	**25%**	**22%**
Attempted suicide	**28%**	**13%**	**13%**

Chapter 10. Injuries: Around 25% of ANA CHA participants report an injury in the 12 months prior to the survey. The most common injuries were minor cuts, scrapes or bruises (36%), broken or fractured bones (31%), and major sprain or strain (29%). The highest proportion was in the 30 – 49 year age range (47%). For women, heavy drinking is associated with having been injured in the past 12 months.

In addition to the association with heavy drinking, **proportionally more Band members who had been told by a health professional that they had mercury poisoning report having been injured over the past 12 months. For those under 50 years of age, a tendency was observed for those who ate fish several times a week or more at 10 years of age.** Motor difficulties associated with mercury poisoning may explain these results.

Chapter 11. Disability and homecare: Thirty percent of ANA Band members report that they are limited in the kinds or amount of activity they can do at home, work or otherwise because of a physical or mental condition or because of a health problem. Limitations increase with age and are more present among women. The most common limitations are: seeing or reading newsprint (33%), difficulties in climbing a flight of stairs, walking 5 minutes without resting, problems related to hearing (23%), and their speech is not understood by those who speak the same language (23%). Limitations in the kind and amount of activities were related to having an injury in the 12 months prior to the survey, at least one chronic disease, obesity, and poorer health. **The likelihood of activity limitation is almost 3 times higher among those who have been told by a health professional that they have mercury poisoning, taking into account age, sex, heavy drinking, injury in the past year, at least one chronic disease, and obesity.** For persons under 50 years of age, ANA Band members who ate fish several times a week or more at 10 years of age, the Odds Ratio is 2.04 [C.I. 95th 0.98 – 4.26] p = 0.06, taking into account age, sex, heavy drinking, at least one chronic disease, and obesity.

Chapter 12. Health care access: The questions from the First Nations Regional Health Survey on Health care access focussed on the barriers to health care, access to the Non-Insured Health Benefits (NIHB), traditional medicine use and routine medical examinations.

Approximately half of ANA Band members indicate that there was at least one barrier to health care access, notably the availability of services: doctor or nurse not available in the area and long waiting lists. **For Band members on reserve 49% experience barriers to availability of services compared to 30% off reserve.** One person in four indicates that in accessing health care, they feel uncomfortable because of racism or the health care provided was inadequate. Nearly one in four cite economic (21%) or systemic barriers (23%).

Compared to other First Nations in Ontario living on reserve, a larger proportion of ANA Band members on reserve indicate that they feel health care was inadequate (26% vs. 21%), unavailability of doctor or nurse (36% vs. 21%), unavailability of health facility (23% vs. 12%) or service (21% vs. 13%), and difficulty in getting traditional care (21% vs. 14%). On the other hand, a smaller proportion of ANA Band members on reserve indicate long waiting lists (28% vs. 34%), NIHB coverage (14% vs. 27%) and prior approval (10% vs. 19%).

Over two thirds of ANA Band members (67%) report that they have no difficulties in accessing NIHB services. However, women report more difficulties compared to men (38% vs. 25%) and older women (30 – 49 years of age and 50 years and more) report more difficulties compared to younger women (18 – 29 years of age): 41%, 47%, 21%, respectively. More ANA Band members, with difficulties meeting their basic needs in terms of transportation, report difficulties in accessing NIHB services compared to those with none (40% vs. 26%; p=0.03).

Among those who report difficulties accessing NIHB services, 80% have at least one chronic disease and 35% have been told that they have mercury poisoning. **The likelihood of Band members to whom a health professional has told they have mercury poisoning reporting difficulty in accessing NIHB services is twofold higher than the others (Odds Ratio = 2.13 [95th CI: 1.03 – 4.37], taking into account age and sex.**

Proportionally fewer ANA Band members on reserve report difficulties in accessing NIHB services compared to other First Nation communities (ANA: 32%; Ontario: 39%; Canada 35%), however, over twice as many report difficulties accessing vision care (ANA: 20%; Ontario: 8%; Canada; 9%), a condition that this report and several studies have shown is associated with mercury poisoning.

Less than a third (31%) of ANA Band members report using traditional medicine and there is no difference between those who live on or off reserve. The use of traditional medicine increases with age. About 40% of ANA participants report having consulted a traditional healer, either in the 12 months prior to the survey or a longer time ago; almost half of ANA participants report never having consulted a traditional healer. Proportionally fewer ANA Band members on reserve (30%) use traditional medicine compared to 46% among other First Nations in Ontario and 40% among First Nation communities in Canada.

The proportion of Band members who report routine medical examinations for blood pressure and blood sugar is similar among ANA Band members and other First Nation communities in Ontario and in Canada (50% – 70% for men and women); however for vision/eye care, cholesterol, and a complete physical examination, it is approximately 10% lower. A greater proportion of women ANA Band members report that they have never had a mammogram compared to other First Nations in Canada and in Ontario, while the percentages are similar for the PAP smear test.

Chapter 13. Diet, nutrition and food security: About a third of ANA-CHA participants, more women than men, report eating nutritious balanced meals always or almost always, and about half report sometimes. These results are similar to those observed in other First Nations in Canada. However, when examining the types of food, fewer ANA Band members on reserve consume vegetables, fruit and milk products daily compared to First Nations in Ontario and in Canada, and more report daily consumption of fast foods.

Walleye is the most frequently consumed fish species, as well as the most consumed traditional food overall, with 30% of the participants reporting eating it often in the 12 months prior to the survey. Wild blueberries and wild strawberries are the most frequently consumed wild berries and a majority of participants report consuming wild rice at least a few times over the past year. With the exception of moose, most participants do not report consuming game animals or fowl. Most participants (70%) report that someone shared traditional food with them in the previous 12 months.

We calculated food security status using the same questions and calculations as the First Nation Regional Health Survey (2008/2010), which classifies food security into 3 categories: (i) Food secure (ii) Moderately Food Insecure and (iii) Severely Food Insecure. A total of 43% of participants are food secure. About a third (31%) of the participants households are moderately food insecure, and about **a quarter (23%) of the households are severely food insecure**; there is no difference between participants living in Grassy Narrows and those living off reserve.

Food security increases with income (15% in the lowest income adequacy bracket and 82% in the highest) and is higher among those who share traditional food (59% of those who are food secure share in traditional food, compared to 19% of the severely food insecure). Severe food insecurity varies with civil status; 42% among persons who are divorced, separated or widowed; 32% for those who are single, and 15% for those living in couple.

Severe household food insecurity is considerably higher among ANA Band members on reserve than in First Nation communities in Ontario and in rural Canada (25% vs. 15% and 13%), but the percentage of those who are food secure is similar to that of First Nations in rural communities in Canada and about 10% lower than in First Nations communities in Ontario.

Chapter 14. Physical activity: Nearly half of ANA CHA participants report walking or practicing moderate activities at least 35 minutes daily. Men's daily routine is more active than that of women; there are no age-related differences. Physical activity is more common in participants who report thriving, who are not obese, who report fewer limitations in their activities due to a mental or physical condition, and who had a greater sense of control over their life.

The most frequent activities in the year prior to the survey are: walking (80%), fishing (51%) and swimming (35%). Proportionally more persons who fish often eat walleye (between 45% to 50%, depending on age) compared to those who do not fish (16% to 20%, depending on age).

Chapter 15. Smoking, drinking and drug use: Almost half of participants currently smoke (46%), most daily. There is no difference between men and women, but men tend to smoke more cigarettes per day than do women. Although proportionally fewer older persons (50+) smoke compared to younger ones, older persons who do smoke, consume considerably more cigarettes per day. **Compared to the others, proportionally more persons smoke daily among those who are experiencing psychological distress and thought about or attempted suicide.** The proportion of persons who do not smoke is higher among those who have been told by a health professional that they have mercury poisoning, who have high blood pressure, or who report they require homecare.

Despite the high proportion of smokers, 72% of participants live in a smoke-free home. Proportionally slightly more ANA Band members on reserve smoke daily or occasionally (66%) compared to First Nation communities in Ontario (50%) and First Communities in Canada (57%); however for those 60 years and more, proportionally fewer ANA Band members smoke daily or occasionally (ANA: 12%; Ontario: 18%; Canada 25%) and a similar percentage live in smoke-free homes.

One person in four reports using cannabis daily or almost daily with more men than women and more younger persons compared to older persons. Proportionally more Band members on reserve (38%) compared to Band members living off reserve (21%) report cannabis usage daily or almost daily. Few persons report using hard drugs and the maximum frequency was once or twice over the past twelve months.

One person in four (25%) report not drinking alcohol over the past 12 months; proportionally more women compared to men and non-drinkers increased with age. For those over 60 years of age, 71% did not drink over the past year. The First Nation Regional Health survey defines heavy drinking or binge drinking as 5 or more drinks per setting on one occasion at least once a month. Using this definition, we classified persons into (i) non-drinkers (26%), moderate drinkers (20%) and heavy drinkers (54%). Among ANA Band members on reserve, 58% are heavy drinkers compared to 49% among other First Nation communities in Ontario. FNRHS in Canada reports the percentage of drinkers that are heavy drinkers; in communities in Canada, 64% of drinkers binge drink, in ANA, it is 73%. The contribution of drinking was accounted for in all of the analyses on determinants of health status.

There are proportionally more abstinent and moderate drinkers among women, among persons over 50 years of age, non-Band members, non-smokers, persons who have been told by a health professional that that had diabetes, mercury poisoning, persons who don't use cannabis. Abstinent and moderate drinkers have a higher score on the mastery scale and proportionally more have low psychological distress; fewer have thought about committing suicide and fewer have attempted suicide.

A total of 38% report that they have sought treatment for substance abuse. This percentage is over twice as high as those who have sought treatment for substance abuse in other First Nation communities in Ontario (16%). Among those who have sought treatment, 22% were abstinent in the past year and 19% drank moderately.

Chapter 16. Community wellness and traditional culture: The analyses in this section included only persons, Band members and non-Band members, who reside in Grassy Narrows. The survey questions included the challenges listed in the First Nation Regional Health Survey. **Challenges identified by more than half of the persons who live in Grassy Narrows are, in descending order: alcohol and drug abuse, housing, employment, education and training opportunities, water supply, funding and health**. Among those who wrote in other challenges, the top three were mercury poisoning, water quality and logging. As age increases, proportionally more persons see health as a challenge. For those 50 years and over, 62% see it as a challenge. In terms of progress, over 50% indicate that some or

good progress has been made with respect to education and training opportunities and housing, 40 – 46% progress with respect to health and water supply, between 30 and 40% indicate some or good progress for culture, natural environment and resources, funding, employment/number of jobs.

Compared to other First Nations in Canada ANA Band members on reserve are more **positive about changes in their community, particularly as concerns control over decision, funding, natural environment/resources and gang activity, health, educations and training opportunities and housing.** From the FNRHS list, the most commonly reported strength was family values, identified by 53% of the participants and good leisure or recreation activities (44%) are also reported by almost half of the participants. The ANA-CHA survey included **"Persistence in fighting for our rights" as a strength of the community; 45% endorsed this as a strength.**

Almost 60% of persons living in Grassy Narrows participate sometimes, always or almost always in the community's cultural events and **48% report that they participate at the least sometimes in community events to recognize their rights**.

TABLE OF COMPARISON WITH OTHER FIRST NATION COMMUNITIES

The ANA Community Health Assessment survey used many of the same questions as the First Nations Regional Health Survey (2008/2010) (FNRHS). This allowed us to compare ANA responses with other First Nations in Canada (11,043 adults over 18 years and older) and Ontario (1500 adults 18 years and older). Since the FNRHS was carried out on reserves, here we present the ANA-CHA survey responses for ANA members on reserve.

The table includes some of the major differences. For the specific chronic health conditions, we include those that are similar as well as those that are different.
Bold script indicates that ANA is worse off compared to First Nations in Ontario, Canada or both.

	ANA on reserve	**First Nations in Ontario**	**First Nations in Canada**

a The prevalence of these chronic conditions are higher among Band members living off reserve: Learning disability: 11%; Cognitive/mental disorders: 11%; Heart disease: 10%; High blood pressure: 32%.

SUMMARY OF FINDINGS ON MERCURY POISONING AND FISH CONSUMPTION

Health professional has told you that you have mercury poisoning:

For Band members who reported that they have been **told by a health professional that they have mercury poisoning** compared to those who reported that they have not been told by a health professional that they have mercury poisoning:

- There are proportionally more who are **not working** (61% vs. 43%).
- They constitute 65% of those who indicate that they are not working because of **poor health or disabled**.
- They have **lower incomes** both individually ($p<0.05$) and by household ($p<0.05$).
- More are **limited in their activity because of a physical or mental condition or because of a health problem** (often 24% vs. 6%; sometimes: 31% vs. 11%)
    - The likelihood of activity limitation is threefold, taking into account age, sex, heavy drinking, injury in the last 12 months, at least one chronic disease, and obesity.

      Odds Ratio 3.16 [C.I. 95th 1.31 – 7.77]
- More difficulty **accessing NIHB** services, taking into account age and sex.

  Odds Ratio = 2.13 [95th C.I. 1.03 – 4.37]
    - 36% of those who have trouble accessing vision care have been told by a health professional that they have mercury poisoning.
- Co-morbidity:
    - They are over 4 times more likely to have **multiple chronic health conditions** (4 or more chronic health conditions), taking into account age and sex.

      Odds Ratio = 4.62 [95th C.I. 2.18 - 9.80]

- The likelihood of having a health professional tell you that you have one of or more of the above **neuropsychological disorders** is fivefold greater.

  Odds Ratio = 5.23 [95th C.I. 2.29 – 11.9]

- They are 5 times more likely to have been told by a health professional that they have **allergies.**

  Odds Ratio = 5.85 [95th C.I. 2.74 – 11.89]

- The likelihood of **blindness or vision problems that cannot be corrected by glasses** is over three times stronger, taking age into account.

  Odds Ratio = 3.3 [95th C.I" 1.21 – 9.2]

- Those over 30 years of age are almost 4 times more likely to have been told by a professional that they have **high cholesterol**, adjusted for diabetes and high blood pressure.

  Odds Ratio = 3.7 [95th C.I. 1.10 – 12.7]

- Those over 30 years of age are 3 times more likely to have been told by a health professional that they have **arthritis,** taking into account age and sex.

  Odds Ratio = 3.47 [95th C.I. 1.41 – 8.76]

- Those over 30 years of age are 2.5 times more likely to report **chronic back pain**, taking into account age and obesity.

  Odds Ratio = 2.67 [95th C.I. 1.12 – 6.38]

- Those over 30 years of age are 4 times more likely to report **stomach and intestinal problems**, regardless of age or sex.

  Odds Ratio = 3.94 [95th C.I. 1.62-9.80]

  - 40% of persons of persons who have been told by a health professional that they have mercury poisoning suffer from stomach and intestinal problems compared to 12% for those who answer 'no' to this question.

- Those 30 years and over are over 4 times more likely to report **hearing impairment,** taking into account age and sex.

  Odds Ratio = 4.57 [95th C.I. 1.80 – 12.1]

- For those 30 years of age and over, the increased likelihood of being told by a health professional that you have **rheumatism (joint pain)** is almost five fold.

  Odds Ratio = 4.91 [95th C.I. 1.87 – 12.90]

- The likelihood of having had an injury in the past 12 months is over twice as high, taking into account age, education and heavy drinking.

  Odds Ratio = 2.40 [95th C.I. 1.08 – 5.33]

Fish consumption at 10 years of age:

For all Band members who reported that they consumed fish more than several times a week when they were 10 years of age, compared to those who reported that they ate fish less frequently:

- The likelihood of having been told by a health professional that you have **mercury poisoning** is two and half times greater, taking age into account.

  Odds Ratio = 2.51 [95th C.I. 1.17-5.70]

- There is a 2.5 times increased likelihood that a health professional has told them that they have **diabetes**, taking into account age, sex, high cholesterol, eating nutritious meals and body mass index.

  Odds Ratio: 2.58 [95th C.I. 1.05 – 6.36]

- The likelihood of **hearing impairment** is increased 3 times Odds Ratio, taking into account age and sex.

  Odds Ratio: 2.94 [95th C.I. 1.07 – 9.50]

- The likelihood of having been told that you have at least **one nervous system disorder** is twice as high among those who consumed fish more than several times a week.

  Odds Ratio = 2.15 [95th C.I. 1.06 – 4.61]

For Band members **under 50 years of age who report that they consumed fish more than several times a week when they were 10 years old** compared to those who reported that they ate fish less frequently:

- The likelihood of having done **fairly or poorly in school** is almost twice as high (taking into account age and sex.

  Odds Ratio 1.79 [95th C.I. 1.02 – 3.13]

- There are more Band members among those who ate fish several times a week as a child whose **income is under $20,000** compared to those who ate less fish, taking into account age and sex.

  Odds Ratio 1.85 [95th C.I. 1.02 – 3.26]

- For women, fish consumption at 10 years of age is associated with 18 of 58 symptoms, taking into account age, having at least one chronic illness, obesity, drinking and smoking.

- For men, almost all the 58 symptoms are associated with fish eating at 10 years of age, taking into account age, having at least one chronic illness, obesity, drinking and smoking.

- A clustering technique provided a means of grouping symptoms into 6 clusters. Taking into account the relevant co-variables, **childhood fish consumption** is associated with symptom clusters:

  - Peripheral neuropathy
  - Sensory and sensory-motor loss
  - Neuropsychological deficits
  - Motor loss and tingling around mouth
  - Loss of hearing, vision and speech

Current fish consumption:

We examined the prevalence of frequent consumption of **walleye over the 12 months prior to the survey among persons less than 50 years of age,** and whether persons who eat more walleye report more symptoms than those that ate fewer or had not eaten walleye over this period

- One third of all Band members report often eating walleye over the previous year.

- More Band members on reserve (35%) often ate walleye over the past year compared to those living off reserve (19%).

- More Band members off reserve who struggle to pay for food eat more walleye (27% vs. 8%). This is not the case for those who live on reserve.

- Taking into account fish consumption at 10 years of age and other relevant co-variables, for all Band members, **often eating walleye in the past 12 months** is associated with **symptoms clusters** of:

- Peripheral neuropathy
- Sensory and sensory-motor loss
- Motor loss and tingling around the mouth

Finally, all of the symptom cluster analyses were rerun without those who have been told by a professional that they have mercury poisoning (n = 30); the associations were similar.

Father a fishing guide:

For Band members who indicated that their **father was a fishing guide** compared to those who indicated that their father had not been a fishing guide.

- The likelihood of having been told that you have **mercury poisoning** is almost five times more for those whose father was a fishing guide is, taking age into account.

  OR = 4.76 [95th C.I. 1.55-15.0]

- For persons over 30 years of age, the fathers' of almost all of those who have been told that they have mercury poisoning (96%) were fishing guides.

- The likelihood of having been told that you have at least one nervous system disorder is twice as high among those whose father was a fishing guide.

  OR = 2.15 [95th C.I. 1.06 – 4.61]

Mercury Disability Board

- A total of 95 Band members report that they have made a claim to the Mercury Disability Board, of these, 21 (22%) indicate that their claim was accepted, 11% that their claim is in progress, and 67% report that their claim was refused.

- Men whose claim has been accepted by the Mercury Disability Board have more social support that those whose claim has been refused.

OVERALL CONCLUSIONS AND RECOMMENDATIONS

The ANA-CHA is a community driven endeavour, which provided high quality data. Almost 80% of the people living in Grassy Narrows participated in the survey, which was coordinated and administered by ANA Band members. Participants were informed prior to and during the survey that the results belong to ANA and will be used to improve their health and wellbeing. Knowledge of community ownership of the data contributed to the success of the survey.

The questionnaire survey was adapted from the First Nation Regional Health Survey (2008/2010) to meet ANA's needs and concerns, This allowed us to (i) compare the situation of ANA Band members on reserve with other First Nation communities in Canada and in Ontario, and (ii) examine how consumption of mercury-contaminated fish affects ANA's health and wellness.

The findings show that the health and wellbeing of ANA cannot be understood without taking into account their history of mercury poisoning and its consequences. The results of the ANA-CHA provide clear evidence that the physical and mental health of ANA Band members is poorer than that of other First Nation communities in Canada and Ontario. They likewise show that people who ate more fish show worse health and wellbeing. These findings from the ANA-CHA survey are consistent with the extensive scientific literature, which show that methyl mercury from fish consumption is harmful, particularly to the nervous system.

The ANA-CHA survey results reveal that more people with diagnosed mercury poisoning have several other chronic health conditions and lower income, compared to the others, and adults under 50 years of age, who ate more fish as children, report more symptoms of nervous system dysfunction, poorer success in school and lower income.

The major findings are:

- The physical and mental health of ANA Band members is poorer than that of other First Nation communities
- The differences with other First Nations are not observed for all chronic health conditions
- In ANA, diabetes poses further challenges for health care
- A much lower prevalence of diagnosed heart disease in ANA constitutes an unexpected finding.

- Mercury contamination of fish resources has gravely affected ANA's health and social and economic wellbeing, and deprived the community of a traditional, highly nutritious food.
- There are fewer elders in Grassy Narrows compared to other First Nation communities in Ontario and Canada
- For the most part, individual wellness of the ANA community is considerably worse than that of other First Nations in Ontario and in Canada.
- Overall, women report poorer physical and mental health compared to men. Women
- Deprived of a nutritious food source (fish) with omega-3 fatty acids and other nutrients, coupled to a reduced earning capacity, there is a high prevalence of food insecurity in Grassy Narrows.
- Current health and social services programs are inadequate in addressing many of the issues concerning the health and wellbeing in the ANA community.

1. **The physical and mental health of ANA Band members is poorer than that of other First Nation communities.** The most striking differences are for health perception, chronic health conditions, psychological distress, suicide, income, food security and activity limitations. These differences are primarily, but not solely, with outcomes that are associated with childhood fish consumption and/or co-morbidity with mercury poisoning. For many outcomes, the largest differences are for middle aged persons (30 – 49 years)

Recommendation: Because of these differences, ANA requires additional resources for physical and mental health care, as well as programs to compensate for their economic loss.

2. **The differences with other First Nations are not observed for all chronic health conditions:** Of the 28 chronic health conditions that were surveyed among First Nations in Canada, Ontario and ANA, the prevalence for 20 conditions is similar, as is the distribution of Body Mass Index. The prevalence of diabetes in ANA is higher than in other First Nation communities in Canada, but similar to Ontario. ANA Band members on reserve have a higher prevalence of the following chronic health conditions: allergies, stomach and intestinal problems, blindness or visual problems not corrected by glasses, hearing impairment, rheumatism (joint pain), psychological or nervous disorders and tuberculosis. With the exception of tuberculosis, all of these chronic conditions show co-morbidity with mercury poisoning (see below). In contrast, the

prevalence of heart disease is considerably lower in ANA, even among the elderly.

Recommendation: High co-morbidity observed in ANA needs to be considered in clinical care, future studies and compensation for mercury poisoning

3. **Diabetes poses further challenges for health care.** Compared to other First Nation communities, more ANA persons with diabetes are being treated with insulin. Moreover, diabetic co-morbidity is likewise different; proportionally more ANA diabetics report neuropathy, vision problems, circulatory difficulties, lower limb issues and infections. It is noteworthy that these symptoms are likewise associated with mercury exposure, and, survey results show neuropathy, vision problems and lower limb problems are likewise associated with childhood fish consumption.

   The observed association between childhood fish consumption and diabetes requires follow up. Published studies on a possible association between mercury exposure and diabetes are inconsistent, however, most were carried out with populations who eat sea fish and mammals, which have high levels of selenium and omega-3 fatty acids, or with persons whose mercury exposure was well below those that have been reported for Grassy Narrows.

Recommendation: The possible contribution of mercury exposure to diabetes, its consequences and care, is an important issue for this community and needs to be followed up through clinical and/or epidemiological studies in order to ensure that diabetics are receiving appropriate care.

4. **Lower prevalence of heart disease: an unexpected finding.** While this may represent a positive outcome, it may also reflect a higher mortality rate among those with heart disease. This is all the more surprising since myocardial infarction has been associated with methyl mercury exposure at concentrations much lower than those that have been reported for Grassy Narrow residents. The present survey cannot answer the question as to whether heart disease presents differently in mercury-exposed persons or whether mercury, or something else in the Grassy Narrow environment, is protective of heart disease.

Recommendation: There is an urgent need to carry out clinical and/or epidemiologic studies to understand these findings; anecdotally, heart disease is considered by ANA community members as one of the major causes of death.

5. **Mercury contamination of fish resources has gravely affected ANA's health and social and economic wellbeing, and deprived the community of a traditional, highly nutritious food.** The results of the survey are consistent with the extensive scientific literature on the health effects of methyl mercury from fish consumption, notably on the nervous system.

    - **Sixty persons in the ANA community have been told by a health professional that they have mercury poisoning.** Persons with mercury poisoning report significantly more other chronic health conditions compared to those who do not have mercury poisoning, independently of age and sex. These include: neuropsychological disorders, blindness or vision problems that cannot be corrected by glasses, arthritis, chronic back pain, stomach and intestinal pain, high cholesterol, allergies, hearing impairment and rheumatism. While the survey cannot determine whether these ailments are a result of mercury toxicity, this co-morbidity needs to be taken into account when considering health care for persons with mercury poisoning. Persons with mercury poisoning likewise have proportionally more accidents and are more limited in their activities. Over 60% are not working, two thirds of these because of poor health or disability, and as a consequence, they have lower incomes. Despite their illnesses, they have more difficulty than others in accessing Non-Insured Health Benefits (NIHB) services, particularly for vision care, a known outcome of mercury exposure.

Recommendations: There is an urgent need to improve care for persons with mercury poisoning, taking into account co-morbidity, loss of livelihood and loss of mobility.

There needs to be services, such as physiotherapy, occupational therapy, speech therapy, pain management, counselling and traditional healing, not only for those with diagnosed mercury poisoning, but also for others in the community with sub-clinical symptoms (see below).

Greater support for accessible infrastructures and mobility aids are required. There is a clear need for a long-term care facility in Grassy Narrows for those who can no longer care for themselves.

It is noteworthy that a third of Band members responded that they did not know if a professional had told them that they have mercury poisoning, a very much higher proportion compared to responses for the other chronic conditions. Although persons who answered that they 'did not know' report significantly fewer symptoms compared to persons who answered 'yes', they have significantly more symptoms compared to those who

answered 'no' to this questions, taking into account age and sex. It is not possible to know from the survey why there is this high percentage of persons who answered not knowing whether a professional has told them that they have mercury poisoning.

Recommendation: This result reflects the need for regular examinations for sub-clinical and clinical effects of mercury, including neuropsychological assessments.

- **For those under 50 years of age, childhood consumption of fish several times a week or more is significantly associated with many aspects of their health and well-being**. Since mercury toxicity can be progressive, we examined persons less than 50 years of age with respect to their fish consumption during childhood. Those who consumed more than several fish per week as a child did more poorly in school compared to the others. This translates into earning capacity: more Band members who ate fish several times a week as a child report an annual income of under $20,000, compared to those who ate less fish, taking age and sex into account. These persons likewise have more activity limitations, even when considering those with no diagnosis of mercury poisoning. Persons who ate more fish when they were children report a higher frequency of symptoms of nervous system damage, difficulty concentrating and motor disorders, independently of age, sex, chronic health conditions (including diabetes), drinking habits and nutrition.

Recommendations: Prenatal and childhood exposure is known to be particularly harmful for development. The results here indicate that this continues into adulthood, affecting individual and community wellbeing. There is a need for adult education and job training programs, which take into account deficits associated with mercury poisoning, as well as programs to compensate for economic loss.

The study could not answer the question about whether the effects will get progressively worse, but the group that shows the greatest effects are those between 30 and 49 years of age. There is a need for regular medical ad neuropsychological examinations by professionals with a good knowledge of mercury poisoning

6. **The results of the survey are consistent with the extensive scientific literature on the health effects of methyl mercury from fish consumption,** notably on the nervous system. Indeed, mercury is a well-known toxic substance, whose effects on the nervous system are on a dose-dependent continuum of loss of function and wellbeing; prenatal and childhood exposure is

particularly harmful since the nervous system is in rapid development. Although there are fewer studies on other health outcomes, several studies have shown effects on the cardiac function and disease, while the reports on metabolic disorders are less consistent.

Recommendations: Health professionals that treat ANA community members, including providers of visual care, physiotherapy, etc. and indigenous and non-indigenous health care workers and educators, should have training on the effects of mercury poisoning.

Since racism is cited as a barrier to health care, a strong therapeutic relationship with the community and individuals is an important part of effective treatment.

7. **There are fewer elders in Grassy Narrows compared to other First Nation communities in Ontario and Canada.** Since the percentage of elders may result from sampling bias (i.e. fewer older persons participated in the ANA CHA survey) we verified this finding with other surveys and the most recent government census. The proportionally fewer elders in Grassy Narrows suggests that many people have died prematurely and that those who remain are the 'survivors' from the effects of mercury poisoning, but this cannot be verified by the present survey. It should be noted that half of the elders (those over 50 years of age) have been told by a health professional that they have mercury poisoning.

   Fewer elders has far-reaching consequences: (i) Fewer persons are available to transmit traditional culture and knowledge. (ii) Fewer elders are present in immediate and extended families to help out. It is noteworthy that in Grassy Narrows, more elders are currently employed compared to elders in other communities, although this may reflect that, on average, the elders in Grassy Narrows are younger than those in other First Nation communities. Cultural continuity and connectedness have been shown to be protective for emotional wellness (see below).

Recommendations: Long term, stable institutions to facilitate the sharing of knowledge, culture and traditional healing by Grassy Narrows should be supported and augmented. Where local elders are not available, programs such as elder-sharing with other First Nation communities should be explored.

Efforts should be made to ensure that the elders (both present and future) remain as healthy as possible.

8. **For the most part, the mental health and individual wellness of the ANA community is considerably worse than that of other First Nations in Ontario and in Canada.** The most striking evidence of the poorer mental health and wellness is suicide. Etkin, in his book on disaster theory,[13] writes that prior to 1970, no *suicides* were ever recorded at *Grassy Narrows*. In 1977–1978, there were 28 attempted *suicides* of people aged 11–49 years of age out of a population of about 500. In the ANA-CHA survey, 91 Band members indicate that a family member or close friend has committed suicide, 113 have thought of committing suicide (41% of respondents to this question) and of these, 83 (76% of the 109 who responded) have attempted suicide. While 45% of persons who had attempted suicide indicated that it was as a child or adolescent, 55% indicated that it was as an adult and 19 persons responded that the attempt was during the past year.

   When compared to other First Nation communities in Ontario and Canada, approximately three times more ANA Band members report that a close friend or family member committed suicide, approximately one and a half times more have thought of committing suicide and approximately twice as many have attempted suicide. Furthermore, the proportion of those who attempt suicide among those who think about suicide is approximately 54% among other First Nation communities and 76% in Grassy Narrows.

   Psychological distress is the major determinant of suicidal events and the ANA-CHA survey shows that, compared to other First Nation communities in Canada, almost three times as many ANA women and twice as many ANA men suffer from high psychological distress. Among the protective factors for psychological distress are: good health, school success, a nutritious diet, social support, a sense of belonging to the community and mastery over one's destiny. The risk factors include: food insecurity, financial insecurity, disability, injury and chronic health conditions, notably nervous system disorders and heavy drinking. Many of these factors (good health, school success, food insecurity, financial insecurity, disability and chronic health conditions) are associated with mercury poisoning and/or higher fish consumption as a child.

[13] Etkin D. Disaster Theory: An Interdisciplinary Approach to Concepts and Causes. Butterworth-Heinemann, 2014, p. 138.

Recommendations: The results clearly indicate that current mental health and suicide programs are insufficient to reduce suicide and improve mental health. In addition to providing better and more services for individuals, there is a need for a greater community focus.

Long-term stable programs should be improved to maximize the protective factors and minimize the risks. The protective factors for psychological distress identified in the present survey need to be reinforced and coupled with cultural continuity or connectedness, which have been shown to be a factor associated with lower youth suicide in First Nation communities[14] and better mental health.[15]

Interrelationships between the natural environment (benefits and risks) social factors, behaviours and health need to be addressed, particularly in this community that has experienced a continuing environmental disaster.

9. **Overall, women report poorer physical and mental health compared to men**. More women than men report poorer health, at least one chronic health condition, high psychological distress, suicidal ideation and attempted suicide. Women report a higher frequency of symptoms. In the multivariate analyses of symptoms, more factors contribute to increased frequency of symptoms in women compared to men. It is noteworthy that despite poorer health, women work more paid hours compared to men.

Recommendation: There is a need to adequately address gender differences in order to provide adequate physical and mental health care to women as well as men.

10. **Deprived of a nutritious food source (fish) with omega-3 fatty acids and other nutrients, coupled to a reduced earning capacity, there is a high prevalence of food insecurity in Grassy Narrows.** The Grassy Narrows community was not only poisoned by mercury through their fish consumption, but also deprived of an important nutritious food source, known for its health benefits. The life of Grassy Narrows centered on fish for economic, cultural and nutritious benefits. Even today, two thirds of the community fish, and half of those who fish eat fish often. Walleye is the most fished and eaten.

[14] Chandler MJ and Lalonde C. Cultural continuity as a hedge against suicide in Canada's First Nations. Transcultural Psychiatry 35 : 191-219 ; 1998.

[15] Snowshoe A. et al, Cultural Connectedness and Its relation to mental wellness for First Nations youth, Journal of Primary Prevention 38 : 67-86 ; 2017.

The loss of this natural resource, coupled with poverty, is associated among other factors with disability, illness and poor academic achievement. 24% of persons in Grassy Narrows suffer from severe food insecurity; the prevalence is almost twice as other First Nations in Ontario and Canada. Only 15% of those in the lowest income adequacy bracket are food secure.

Food security status is associated with the quality of the diet. 25% of those with severe food insecurity rarely or never eat nutritious meals. Persons who have someone who shares traditional food with them are more food secure. In an article published in the Lancet in February 2018, ***Dr. Jane Philpott wrote:*** *"One First Nations elder reminded me that "words do not feed a table." His point was that rebuilding trust demands action, including the resources to accomplish these goals."*

Recommendations: There is an urgent need for long-term, stable programs, which provide nutritious food to people living in Grassy Narrows.

The efforts to discover and recover clean fishing areas for the community should be intensified. In addition to fish, the community needs the means to harvest other traditional foods, such wild rice, moose and hare to be shared with the entire community.

Community gardens should be established and community kitchens, which can provide nutritious food for those who are disabled and ill, should be set up.

11. **Current health and social services programs are inadequate in addressing many of the issues concerning the health and well-being in the ANA community.** In the same article in the Lancet, **Dr. Philpott** writes: *"Correcting for these inequities [in health] requires more than better health care. Health-care workers who respect Indigenous knowledge and practices are vitally needed, and health-care systems must be improved. But real change requires the recognition of the inherent and treaty rights of Indigenous peoples, along with investments in the social determinants of health."*

Recommendations: Recognition of the consequences of the major disaster that took place in the English-Wabigoon River System and the continuing impact of mercury poisoning should form the basis of designing and delivering an adequate health and social services system.

While many of the problems accessing health care are similar to other First Nation communities, there are differences in the proportion of persons that need to access these services, with a resulting increase in cost. Increased funding should be provided to account for the increased cost of providing services in a mercury-impacted community.

Furthermore, some of the specific needs that results from mercury poisoning, such as visual care, the treatment of diabetes and other diseases, physiotherapy, speech therapy, etc, need to be more available. Off reserve services need to be more accessible and culturally sensitive.

It is noteworthy that in this context twice as many ANA Band members on reserve (11%) have an immediate family member placed in a long-term care facility located outside of the community or off reserve compared to other First Nations in Ontario (6%) and the percentage of those who were placed in a long-term care facility when they were less than 60 years of age is considerably higher.

Recommendation: A long-term care facility, that meets the needs of community members, should be built in Grassy Narrows**.**

12. **Despite many physical and mental disabilities, ANA community members make important individual and collective efforts to improve their health and well-being.** Grassy Narrow's 40 year struggle for recognition of their situation and their fight for adequate compensation and care is well-known, through numerous books, media coverage of their plight and the many community activities, including a long-standing barricade against logging on their territory and community efforts for fish management and remediation of the river system.

    The ANA-CHA provides a glimpse into how individuals are coping with their situation. Almost half of participants in the survey indicate that they have furthered their education, with trade, technical or vocational school, community college, university or training for specific employment. In comparison with other First Nation communities in Canada, the labour force participation rate for Band members on reserve is 76%, while for Canadian First Nation communities it is 69%. Compared to other First Nations in Canada ANA Band

members on reserve are more positive about changes in their community, particularly as concerns control over decision, funding, natural environment/resources and gang activity, health, educations and training opportunities and housing.

The survey reveals the efforts to change personal behaviours that are harmful to health. While the percentage of smokers is higher in Grassy Narrows compared to other First Nation communities, the percentage of those who live in smoke-free homes is similar. Over one-third of the community have sought treatment for substance abuse, and there are fewer heavy drinkers among persons with diabetes and mercury poisoning. Alcohol and drug abuse is recognized as a major challenge of the community. While heavy drinking is higher in ANA compared to other First Nation communities, the analyses in the present report show that alcohol drinking does not explain or influence the associations between fish-eating and poor health outcomes.

Recommendation: Health promotion policies that focus on changing behaviours would benefit from a better understanding of the underlying factors that contribute to these behaviours, such as access to health food, possibility to engage in physical activities due to disabilities, poverty, mental and physical trauma, etc.

From the FNRHS list, the most commonly reported strength is family values, identified by 53% of the participants, and good leisure or recreation activities (44%) are also reported by almost half of the participants. Almost 60% of persons living in Grassy Narrows participate sometimes, always or almost always in the community's cultural events and **48% report that they participate at the least sometimes in community events to recognize their rights**.

In the words of **Dr. Jane Philpott:** ***"The path ahead begins with the recognition of these rights."***

In the words of **Judy Da Silva:** ***"A clean-up [of the river] would be a new beginning. It would help our health and also help our community to see a brighter future. Now we are used to the darkness."***

Attention: Anjala Purvanathan (Director, Ontario Region) (greatbear@iaac-aeic.gc.ca)
Impact Assessment Agency of Canada
Ontario Region
600-55 York Street
Toronto, Ontario M5J 1R7

Dear IAAC,

RE: The Great Bear Gold Mine Project

On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows First Nation"), we write in response to your March 22, 2024 correspondence to Chief Turtle advising of the Impact Assessment Agency of Canada's (the "Agency") opinion that a federal impact assessment is warranted for the Great Bear Gold Project proposed by Kinross Gold Corporation. In your correspondence you state that "the Agency remains committed to the United Nations Declaration on the Rights of Indigenous Peoples, including the need for meaningful engagement with Indigenous Peoples."

We remind you that the standard for consultation with Indigenous peoples under the United Nations Declaration on the Rights of Indigenous Peoples (the "Declaration") is free, prior, and informed consent. This is the standard of consultation that Grassy Narrows expects with respect to the Great Bear Gold Mine Project, which is consistent with Canada's commitments under the Declaration and the *United Nations Declaration on the Rights of Indigenous Peoples Act* ("UNDRIP Act") and Action Plan.

This letter is provided for the purpose of addressing the role of the Declaration in the Impact Assessment process and should not be taken as Grassy Narrows' comments on Phase 1 of the Impact Assessment.

The Declaration

The Declaration is clear that the standard for consultation with Indigenous peoples is consent:

> Article 32(2): States shall consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free and informed consent prior to the approval of any project affecting their lands or territories and other resources, particularly in connection with the development, utilization or exploitation of mineral, water or other resources.

In 2016, Canada endorsed the Declaration "without qualification" and committed to its "full and effective implementation."[1]

The UNDRIP Act and Action Plan

Under Canada's UNDRIP Act, which provides a framework for Canada's implementation of the Declaration, Canada must ensure that federal laws are consistent with the Declaration. In doing so, Canada must harmonize the *Impact Assessment Act* ("IAA") processes with the Declaration, including Article 32. Canada's June 21, 2023 Action Plan also specifies that the IAA must be implemented in a manner consistent with the Declaration. Measure 51 of the Action Plan, which must be completed in partnership with Indigenous peoples, states that "the Impact Assessment Agency will implement the *Impact Assessment Act* (IAA) in a way that aligns with the objectives and spirit of the UN Declaration." In particular, this includes "carrying out impact assessments in a manner that emphasizes the need to seek free, prior, and informed consent."

Grassy Narrows expects that the Agency will carry out the federal impact assessment process for the Great Bear Gold Project in a manner consistent with the Declaration and that respects Grassy Narrows' right to give or to withhold our free, prior, and informed consent. Anything less would be contrary to Canada's commitments under the Declaration, its own UNDRIP Act and recent Action Plan, and the Crown's stated efforts to "advance reconciliation in a tangible way."[2]

In particular, we urge you to:

a. Carry out the Impact Assessment using a process that is appropriate for Grassy Narrows' unique circumstances, is co-created with Grassy Narrows, and has Grassy Narrows' consent.
b. Pause the Impact Assessment process until the concerns expressed in Grassy Narrows' previous letters have been resolved and Grassy Narrows' consent for the Impact Assessment process is obtained.
c. Include within the scope of the Impact Assessment the question of whether Grassy Narrows' free, prior, and informed consent for the project has been obtained consistent with the Declaration.
d. Ensure that the scope of the Impact Assessment includes all activities that may impact Grassy Narrows' rights and interests.
e. Ensure that no impacts to Grassy Narrows from the project in areas of federal authority are authorized unless Grassy Narrows' free, prior, and informed consent is obtained.
f. Ensure that the decision outcome of the Impact Assessment process has Grassy Narrows' free, prior, and informed consent.
g. Not authorize or otherwise allow the project to proceed without Grassy Narrows' free, prior, and informed consent.

Please provide a written response to this letter, and a written explanation as to how Article 32 of the Declaration will be implemented in the Impact Assessment process in a manner consistent with the Declaration.

[2] https://www.justice.gc.ca/eng/declaration/ap-pa/index.html

The Grassy Narrows Lands Protection Team is willing to meet with the Agency to further discuss the federal Impact Assessment process and our preliminary concerns with the Project as set out in Chief Turtle's March 7, 2024 correspondence to the Agency.

Sincerely,

Joseph B. Fobister

Dear MINES, IAAC, Kinross and Great Bear Resources:

RE: The Great Bear Gold Mine Project

I wrote to you on March 29 and April 15 to provide initial findings from Dr. Kevin Morin concerning metal leaching and acid rock drainage, water quality and hydrogeology with respect to the Great Bear Gold Project.

Please find enclosed:

- Dr. Morin's response to Kinross Gold's consultant, WSP. He concludes that he remains concerned about the many potential environmental impacts that are not recognized and not anticipated by Kinross Gold and about the many impacts that are recognized but poorly addressed and characterized. His concerns pertain to both the proposed advanced exploration and the proposed mining.

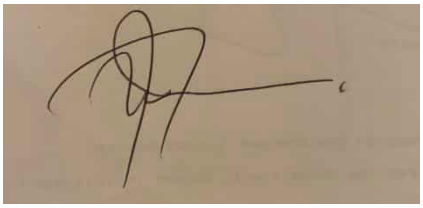
- Dr. Morin's report following his review of the technical documents provided to Grassy Narrows to date: Project Definition; Geochemical Characterization Workplan; Advanced Exploration Program Reclamation Strategy; Program Closure Plan (Draft for Indigenous Review); Hydrogeological Workplan; Surface

Water Quality Workplan; Fugitive Dust Best Management Practices Plan; PTTW Application for Dewatering; Draft Detailed Project Description; Water Treatment during Proposed Exploration and Proposed Mining.

Based on Dr. Morin's export reports, Grassy Narrows is extremely concerned that the project is moving ahead swiftly in the absence of required information and at great risk to the environment, the health, inherent, Treaty and Indigenous rights of Grassy Narrows.

I repeat Grassy Narrows' call to freeze the regulatory process work on this project until full credible information is available and the barriers to Grassy Narrows' meaningful involvement have been resolved. I also repeat Grassy Narrows' position that this project, including the extensive mining of valuable ore that the company is calling "bulk sampling", must be subjected to a rigorous environmental assessment.

Miigwetch,



Joseph B. Fobister, Lead Negotiator of Grassy Narrows Lands Protection Team

Grassy Narrows First Nation
c/o Cavalluzzo
474 Bathurst Street, Suite 300,
Toronto, Ontario M5T 2S6
Attn: Grassy Narrows Lands Protection Team

Dear Grassy Narrows Lands Protection Team,

RE: Great Bear Mining Project - Response to Kinross Gold on MDAG Initial Comments of March 27 2024

I have submitted to you two letters in the past about environmental concerns at the Great Bear Project, dated March 27 and April 11. These letters were based on some of my initial findings from some documents that were within my focus on metal leaching and acid rock drainage (ML-ARD), water quality, and hydrogeology. My review is now complete, including more detailed explanations for those earlier, initial comments as well as additional comments and concerns. My full review accompanies this letter of April 23.

Kinross Gold's consultant, WSP, replied to my first letter of March 27 on April 4. WSP sent a table with 18 issues, listed as "MSDAG [sic] Letter - Comments and Rationale" with a corresponding "GBR Response".

Please note that I did not include full "Rationales" with my initial letters because my detailed review was still in progress. Thus, it was not possible for WSP to provide satisfactory responses. My detailed "Rationales" were provided to you only today.

In any case, I explained that there was little reliable and professionally certified information on ML-ARD, water quality, and hydrogeology at this point for the Great Bear Project. Most Great Bear reports included labels like "preliminary", "draft", and "initial", which meant they were not complete, not certified as reliable, and subject to change one or more times in the future. In fact, some information and designs already changed substantially in 2023, as the accompanying review confirms.

Many of WSP's Responses reflected this. For example, the first WSP Response starts with:

> "The geochemical information presented in these reports represent initial draft documents for the Project, based on data collected in 2022 and early 2023 which was developed [sic] qualified professionals."

As I explained previously, my opinion is that preliminary, draft, and initial reports for the Great Bear Project that are not signed and certified by qualified professionals should not be reviewed. They are subject to change, and already some reports issued in 2023 contradicted others. I expect this to continue for at least a few years until final, reliable monitoring data and testwork are completed.

As a result, it is not worthwhile or meaningful to reply to WSP's Responses to my first letter. There are insufficient information and data at this time to debate and clarify many of my concerns and issues. There may or may not be sufficient information and data in future years. Only time will tell.

Therefore, based on the information available at this time for the Great Bear Project, I remain concerned about the many potential environmental impacts that are not recognized and not anticipated by Kinross Gold and about the many impacts that are recognized but poorly addressed and characterized. My concerns pertain to both the proposed advanced exploration and the proposed mining.

Sincerely,

Kevin A. Morin, Ph.D., P.Geo., L.Hydrogeo.

Report Summary

This MDAG review has focussed on the potential for contamination of water by metal leaching and acid rock drainage (ML-ARD) on, under, and around the Great Bear Project during proposed exploration and proposed mining.

It is important to note that some report titles for Great Bear contain the words "draft", "preliminary" or "initial", meaning newer drafts and revised final versions from Kinross Gold may or may not change from what has been reviewed here. Also, the first cover page for the Detailed Project Description of November 2023 says "draft" while the second WSP cover page does not. Thus, I have found that the reviewed documents for the Great Bear Project as a whole is a confusing mess of shifting, changing, contradicted, and assumed details, with none signed and certified by qualified professionals.

Also, the contents of some documents are password protected. This protected text and information cannot be extracted for detailed evaluation, quotation, review, and comment now or in the future. Thus, they preclude detailed reviews by Grassy Narrows First Nation, which is what Kinross Gold seeks.

Each section of this MDAG review looked in detail at a particular report on proposed exploration and/or proposed mining. The following paragraphs are the summaries taken from each section, and each section should be consulted for details and context.

Section 2 of this MDAG Review

For the password-protected Project Definition Document of December 2022, sufficient details and omissions are present for me to be very concerned about ML-ARD and water-quality degradation during and after the relatively large, at-least-four-years-long proposed Advanced Exploration that would essentially be a first phase of mining at Great Bear. These concerns carry over to the proposed mining.

Although this document is not marked as "draft" and is thus final, it contains many details contradicted by later documents as explained in later sections of this MDAG review. Thus, it is not possible to know exactly what is proposed for Advanced Exploration and, in turn, to know reliably how bad the environmental problems and impacts could be.

Section 3 of this MDAG Review

Problems detected in the January 2023 Geochemical Characterization Workplan include:

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross wants to proceed with

Advanced Exploration.

- All that is available now is 96 rock core analyses according to the September 2023 Reclamation Summary (see below), which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". In any case, the 96 samples were not collected and analyzed as required under the Ontario Mining Act (see next bullet). Thus, Kinross Gold and its consultants, WSP, are guessing how bad the contamination will be, but admit that some of it will be bad, and are likely years away from completing the ML-ARD work required under Regulation 240/00 of the Ontario Mining Act (Mine Development and Closure under Part VII Of the Act).

- The stated approach and methodology used for Advanced Exploration is "based on the requirements" of two British Columbia documents from 1997-1998 (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997). In reality, the Ontario Mining Act says the approach and methodology must be based on the much more detailed 2009 federal Prediction Manual, not just as "guidance" as Great Bear has done. Thus, the work for Advanced Exploration to date does not meet the Ontario Mining Act through Regulation 240/00 and does not meet the 2009 federal ML-ARD Prediction Manual (Price, 2009).

- Even if this Geochemical Characterization Workplan was applicable and consistent with the 2009 federal ML-ARD Prediction Manual, such work requires at least 2-3 years to obtain all required information and interpretations. Therefore, perhaps in 2025 or some year after, there might be sufficient ML-ARD for Advanced Exploration, but not any time soon.

Section 4 of this MDAG Review

Concerns on the Reclamation Strategy from September 2023 include the following.

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross Gold wants to proceed with Advanced Exploration.

- All that is available now is 96 core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". Also, 30 samples of overburden, which is intended to be left on surface and used for reclamation, were collected yet the results are not reported although there is ~50% probability that the overburden will release ML-ARD and thus be toxic. Kinross Gold and WSP are guessing how bad the contamination will be, but admit that some of it will be bad. They are likely years away from completing the ML-ARD work required under the Ontario Mining Act and Regulation 240/00, because the work for Great Bear was not initially consistent with Regulation 240/00. In part, this is because the 2009 federal ML-ARD Prediction Manual (Price, 2009) was not recognized or followed as required. Even the

definitions of ML-ARD acronyms used for the Great Bear Project are not correct according to the federal Manual, which is additional evidence the Prediction Manual is not being followed.

- The bad ML-ARD rock appears to be associated with "rapid acid generation" according to the Program Closure Plan (reviewed in the next section below). This is an incorrect explanation of the phenomenon, but still shows that the bad water quality will start coming out of the disturbed rock, including the underground mine walls, very quickly after initial disturbance. Informally, this is called "lag time" to ML-ARD, but most of the ML-ARD work has not yet been done to quantitatively estimate the lag time beyond "rapid". This contaminating rock will be stored on surface and possibly only later, likely after the lag time, some might be taken underground. When this rock contacts water underground as the workings partially flood and submerge, it will quickly release more contamination. This means the underground water flowing into the surrounding groundwater system, and the surface overflow if any, would have to be monitored and likely be treated for many years or in perpetuity after Advanced Exploration.

Section 5 of this MDAG Review

For the password-protected Program Closure Plan, Draft for Indigenous Review from November 2023, the following concerns were noted.

- In November 2023, the volume of overburden has approximately doubled from previous documents without an explanation. Because overburden generally has a 50% probability of releasing ML-ARD and contaminating water, overburden represents a major but unexamined threat to water quality on, around, and beneath the Great Bear exploration site.

- "Preliminary" criteria are provided for separating "PAG" and "NPAG" rock and for "NML" rock. However, these acronyms are not used in an accurate manner that is consistent with the 2009 federal Prediction Manual (Price, 2009) required by Regulation 240/00. The preliminary criteria are not rational based on ML-ARD science unless justified with detailed and intensive site-specific studies, which have not yet been completed and professionally certified for the Great Bear Project.

- The potential for ML-ARD after closure is presented all the way to detailed predictions of aqueous concentrations in mg/L for on-site water and effluent to the environment, but only after closure and not during operations when the water quality would be reasonably worse. However, these predictions are not explained in any detail, are not justified, appear anomalous, and are not certified by a qualified professional. Some predictions are actually pre-exploration baseline that are erroneously assumed to be re-established immediately at closure. Furthermore, these predictions are missing more than a dozen potential contaminants.

- The "PAG" rock, which would likely create the highest contaminant concentrations, is not included

in this Program Closure Plan, presumably because this "PAG" rock will be backfilled underground. However, when placed underground, this "PAG" rock will likely continue to release severe ML-ARD until submerged, at which point a relatively huge amount of accumulated contamination would be released into the underground water. After the mine is refilled to equilibrium, and the minewater begins flowing into the surrounding groundwater system and through the more than 500 km of permeable drillholes to the environment, it will contaminate large surrounding areas. This major risk to water quality and the environment is not even mentioned in this Closure Plan, which is a major omission.

- The backfilling of "PAG" rock at closure is the largest individual cost item for closure totalling around $10 million. However, this reflects the currently minimum volume based on preliminary, unreliable information. In the worst case, which was assumed in the Great Bear Project Definition and still not disproven here, total closure costs could exceed $20 million.

Section 6 of this MDAG Review

In the Hydrogeological Workplan from December 2022, there is a major omission that would preclude a reliable and comprehensive assessment of current baseline hydrogeologic conditions and of future impacts from proposed mining. The groundwater monitoring network does not extend far enough to the west and northwest, beyond the proposed western portion of the Tailings Management Facility.

Section 7 of this MDAG Review

In the Surface Water Quality Workplan from December 2022, there are insufficient information and details to determine if appropriate work is planned and conducted. This is because important details are listed only as "including". For example, major potential contaminants like manganese and thallium are not specifically listed, but perhaps they are implicitly included? There is no way to know.

Section 8 of this MDAG Review

Based on the final-draft Fugitive Dust Best Management Practices Plan of September 2023 for Advanced Exploration, this work is unacceptable because it grossly underestimates the potential impacts from ML-ARD geochemical contamination of soil, vegetation, water, and biota by dust. This work assumes the on-site sources of dust "would be similar in concentration to the background rock". This is wrong and ignores the ongoing ML-ARD assessment of ore, rock, and overburden.

Section 9 of this MDAG Review

In the PTTW (Permit To Take Water) Application for Dewatering, Final Draft, and its several

important appendices from October 2023, there are alarming errors and ambiguities that should preclude approval of PTTW. These should also trigger a detailed impact assessment, which this PTTW report conversely says is not needed for Advanced Exploration at Great Bear.

In the introduction to the main PTTW report, the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning because the actual total water withdrawal from the local groundwater/surface-water balance would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these flows are unrealistically low as explained here.

The errors begin with groundwater modelling that is based on long-term "steady state conditions" after the mine is "fully developed" and dewatered, and not on the correct, higher-inflow "transient conditions". Thus, inflow, pumping, and dewatering are significantly underestimated by the groundwater model and the PTTW Application. Additionally, there are problems with unrealistically low estimated effects on partial dewatering of Dixie Creek and other creeks and rivers. For example, simulated groundwater levels are around 9 m higher than measured around the mine and Dixie Creek, which artificially and incorrectly prevent additional dewatering of Dixie Creek.

Groundwater levels are shown to be drawn down during dewatering to a maximum of only 36 m even though the dewatered workings will be 600 m deep. This reflects (1) nearly fully dewatering of the shallow overburden and (2) the lack of admission on the likely huge drawdown and much larger "Zone of Influence" in the rock beneath the overburden.

Baseflows into Dixie Creek and other waterbodies can be critical to aquatic, benthic, and terrestrial ecosystems because of groundwater's typically different water quality and temperature compared to water already flowing at the surface. This becomes more critical during droughts when baseflow may be the main source of surface flows. The PTTW Application ignores the fact that more than 34 to 55% of existing baseflow would be lost during Advanced Exploration. It instead points out that the loss to groundwater would be only 2.4% and less of total flow depending on the chosen surface-flow statistic.

Overburden is routinely ignored in this PTTW document and its appendices, despite the proposed hundreds of thousands of tonnes of overburden likely having at least some ML-ARD potential and capacity to degrade water quality. In fact, some underground dewatering would be sprayed on the overburden for dust suppression, which in turn could lead to contaminated runoff across and off the site.

Section 10 of this MDAG Review

In the perhaps-draft Detailed Project Description of November 2023, the first cover page by Kinross says this document is "draft", but the second cover page by the authors, WSP, does not say "draft" so perhaps this is or is not the final document. If so, it has not been signed by qualified professionals and thus should be rejected.

In any case, there are so many problems, misleading statements, errors and omission concerning ML-ARD, water quality, and environmental impacts that they cannot all be summarized well here. These problems include the following.

- There is a false statement that there will be no sources of mercury from the ore processing when in fact the tailings and concentrate from the process will contain mercury. The processing could even cause mercury and other elements to leach more quickly and become more mobile.

- Contrary to the impression given by this Detailed Project Description, cyanide destruction is not perfect and can simply mask the cyanide temporarily in the environment, but the important testwork to determine this has not yet been done for the Great Bear Project.

- Significant impacts on water quality can arise from seemingly benign proposed activities like paste backfill of tailings into the underground mine and dewatered filter-cake tailings. However, the potentials for serious impacts are not recognized or not even mentioned in this perhaps-draft Great Bear document that can supposedly be used to determine what impacts could occur.

- Storm events and equipment upsets can lead to relatively large variations and unexpected impacts, day-to-day or even hour-to-hour, during proposed exploration and proposed mining. Instead, these Great Bear documents use averages like monthly which incorrectly assume flows will be the same every day of a month which is far from reality. Environmental impacts and spills can also be caused by large variations, as well as longer-term averages, so the environmental risks of proposed exploration and proposed mining at Great Bear remain mostly unknown and not identified.

- Nonsense pseudo-scientific statements are used, like the aggregate required to build the project would be “nonreactive mine rock and overburden” which does not exist. This clearly shows that experienced and qualified professionals were not included in the writing of this perhaps-draft Detailed Project Description. If there is a true commitment to “nonreactive mine rock and overburden” which does not exist, then the Great Bear Project stops now.

- There is a lack of ML-ARD assessments for some site components like aggregate.

- There is a prevalent but likely false belief that “NPAG”rock will have little to no impacts on ML-ARD, water quality, and the environment. However, this has not been proven for the Great Bear Project and is likely wrong based on other minesites around Canada. “NPAG” rock can actually generate more acid than “PAG” rock and could still release seriously contaminated levels of many metals and other elements at near-neutral pH.

- The financial assurance to ensure proper and fully paid closure of the proposed Great Bear Project is grossly underestimated based on existing information. Furthermore, the financial assurance should also include contingencies for costs of early or premature closure, but it does not.

- There are likely devastating, expensive, and unrecognized ML-ARD consequences on water quality from the proposed relocation of "PAG" rock into the underground workings after operation.

- The ongoing, unproven, and likely wrong, belief continues that overburden would be environmentally benign, can be used across the site for reclamation, and can be sprayed with water to control dusting when it could instead create contaminating water around, below, and beyond the Great Bear site.

- There are unfounded beliefs that dewatering during exploration and mining would have minimal effects on the local and regional water balance, and would not significantly dewater surface creeks and lakes including their environmentally important baseflow. These false beliefs are based on flawed groundwater modelling for the Great Bear Project explained earlier in this MDAG review.

- There is a false belief that dust blown off the site during proposed exploration and proposed mining and into the surrounding environment, vegetation, soil, water, and aquatic ecosystems is benign at "background" levels.

- A false belief is stated that only elevated and toxic ammonia, and no other contaminating nitrogen species from explosives that consistently accompany the ammonia, will appear in mine water during proposed exploration and proposed mining.

- There is an unsupported and likely substantially underestimated statement that the mine walls in the pits and underground workings "may potentially contribute minor quantities of metals to the mine water" instead of the more typical significant quantities of metals seen at many other minesites around Canada. This is taken as far as the likely ludicrous statement that there would be "Potential for creation of fish habitat in new pit lakes, expected to be re-connected [sic] to the Dixie Creek system".

- There is no recognition of the implications, costs, and impacts of storing months of contaminated mine water on the site should one or more "unexpected" yet currently predictable inorganic contaminants and ML-ARD occur on the site water during and after proposed exploration or proposed mining.

Section 11 of this MDAG Review

In summary for water treatment, Great Bear documents invoke water treatment as the major process that would prevent or minimize environmental impacts of proposed exploration and proposed mining. This is not literally true, because there will be fugitive contaminated water and contaminated dust leaving the site, but this fugitive contamination is ignored or not recognized in many reviewed Great Bear documents.

In any case, water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts, and thus requires intensive study and characterization.

However, at this time, water treatment for proposed exploration and proposed mining is ambiguous and contradictory among the documents. This should be expected because the input flows and input contaminant concentrations (ML-ARD) will not be known reliably for at least a few years. Nevertheless, there are serious concerns about water treatment now including the following.

- Kinross Gold does not expect to treat site water to non-toxic levels. Instead, treatment would only be down to still-toxic levels based on the Metal and Diamond Mine Effluent Regulations (MDMER). Thus, Kinross Gold intends to rely on significant dilution of its contaminated effluent within a "mixing zone" in the Chukuni River. Such a mixing zone would include zones of significant toxicity and would require formal authorization from Fisheries and Oceans Canada. In any case, this discharge of effluent would add to cumulative effects, which is a particular concern of Grassy Narrows First Nation.

- Expensive and intensive treatment for ammonia, derived from blasting residues, is proposed. However, toxic levels of nitrate and nitrite, that always accompany the ammonia and which can cause eutrophication and other impacts in the Chukuni River and Dixie Creek, are completely ignored.

- Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

- Ultrafiltration may substantially reduce effluent concentrations of elements not fully dissolved, mixing-zone size, and cumulative effects. However, there are no details on this ultrafiltration in the reviewed Great Bear documents.

- Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge", which can reach "hazardous" and "special" waste levels in some jurisdictions. Thus, treatment sludge requires the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and sediments including soils and benthic ecosystems. All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge that will remain and be managed somewhere in perpetuity.

1. Introduction

Metal leaching (ML) and acid rock drainage (ARD) are often water-chemistry and water-quality issues for minesites (e.g., Morin and Hutt, 1997 and 2001). As a result, the accurate prediction and control of ML-ARD at mining projects and proposed minesites in Ontario are high priorities of the provincial and federal governments.

This is explained in Part 7 (*Metal Leaching and Acid Rock Drainage Requirements*) of Ontario Regulation 240/00 (*Advanced Exploration, Mine Development and Closure under Part VII of the Act*), and in the federal ML-ARD Prediction Manual (Price, 2009). Section 57(1) of Regulation 240/00 states,

> "A program shall be undertaken to sample all materials remaining on the site that have been excavated, exposed or otherwise disturbed by mining activities, including but not limited to,
>
> (a) drill core;
> (b) metallurgical samples;
> (c) pit walls;
> (d) existing waste rock, ore, concentrate and *overburden* [MDAG emphasis] piles;
> (e) construction rock; and
> (f) tailings."

For detailed guidance, Ontario Regulation 240/00 states,

> "The sampling program shall be conducted by a person who is qualified in Ontario as a professional geoscientist, professional agrologist or professional engineer in accordance with a report prepared by William A. Price on behalf of the Mine Environment Neutral Drainage (MEND) program, entitled 'Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials', MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..." [Price, 2009]

ARD is caused by oxidation of sulphide minerals, which are found at the Great Bear Project, particularly iron-bearing sulphides like pyrite and pyrrhotite. Whether sulphide minerals are present or not, weathering can still lead to accelerated metal leaching (ML). For example, the simple dissolution of near-neutral or alkaline carbonate minerals can release metals like manganese and zinc into the water. Thus, ARD is a subset of the more generic ML.

In practice, ML is not limited to true metals in the Periodic Table, but to all elements that could become potential environmental contaminants. For example, sulphate and nitrate are regularly included in ML assessments. Sulphate can reportedly increase the methylation of mercury and other elements like cadmium and arsenic.

Therefore, ML-ARD is an acronym representing the full spectrum of inorganic water chemistry and quality on, beneath, and around a minesite. Put simply, ML-ARD potential is synonymous with the potential for inorganic water contamination and the degradation of on-site water quality.

Kinross Gold Corporation (Kinross Gold) proposes Advanced Exploration and later mining at its Great Bear Gold Mining Project in the Red Lake mining district of Ontario, approximately 25 km southeast of the Town of Red Lake. The Great Bear Project is located in the Interim Area of Interest for Mining of Asubpeeschoseewagong Netum Anishinabek (ANA), which Kinross documents also name as Grassy Narrows First Nation (GNFN). The Great Bear Project is also in an area where Grassy Narrows First Nation people use the land and water to practice their Indigenous way of life. It is located upstream of the English River which flows directly to the Grassy Narrows village site and Grassy Narrows' most important fishing grounds.

Through Cavalluzzo LLP, the Grassy Narrows Lands Protection Team has asked me, Dr. Kevin Morin of the Minesite Drainage Assessment Group (MDAG), to review and comment on the proposed exploration and proposed mining. This MDAG review focuses on predicted surficial and subsurface ML-ARD and water quality on and around the Great Bear Project.

My qualifications for making the comments in this review document include the following. I have been assessing water contamination at minesites by metal leaching and acid rock drainage (ML-ARD) for 46 years. I have done this at several hundreds of exploration, operating, and closed mining-related sites on all continents except Antarctica, from north of the Arctic Circle to south of the Tropic of Capricorn, in biogeoclimatic zones ranging from virtually no annual precipitation up to a rare daily rainfall of one meter. I earned my Doctor of Philosophy degree in contaminant hydrogeology from the University of Waterloo, where my supervisor was the renowned Dr. John Cherry along with a thesis committee including Drs. Emil Frind (a well-known groundwater modeller) and Eric Reardon (a well-known geochemist). To date, I have authored or co-authored 99 published papers and presentations, five books, and 80 online case studies. I have been and am a peer reviewer for a number of international journals related to ML-ARD and environmental contamination. More details can be found at www.MDAG.com.

The Kinross documents reviewed in the following sections are listed below. Again, the main focus is on the potential for contamination of water by ML-ARD on, under, and around the Great Bear Project during proposed exploration and proposed mining.

- Project Definition Document (December 2022)
- Updated Site Plan
- PTTW Application for Dewatering, final draft (October 2023)
- Fugitive Dust Best Management Practices Plan, final draft (September 2023)
- Reclamation Strategy (September 5, 2023)
- Program Closure Plan, Draft For Indigenous Review (November 2023)
- Surface Water Quality Workplan (December 21, 2022)
- Hydrogeological Workplan (December 21, 2022)
- Geochemical Characterization Workplan (January 9, 2023)
- Preliminary Impact Assessment Methodology, draft (May 31, 2023)
- Preliminary Listing of Potential Valued Components for the Great Bear Project (May 31, 2023)
- Initial Project Description (June 1, 2023)
- Detailed Project Description (November 2023)

- PowerPoint Presentation by Kinross to ANA (November 10, 2023)
- ANA IPCA Map

It is important to note that some report titles above contain the words “draft”, “preliminary” or “initial”, meaning newer drafts and revised final versions from Kinross Gold may or may not change from what has been reviewed here.

Also, the contents of some documents above are password protected. This protected text and information cannot be extracted for detailed evaluation, quotation, review, and comment now or in the future. This precludes the detailed review by Grassy Narrows First Nation that Kinross Gold seeks. I strongly recommend that unlocked versions of all Kinross documents be obtained and kept by Cavalluzzo LLP and the Grassy Narrows First Nation for future reference and usage.

2. Project Definition Document (December 2022)

The Great Bear Resources Great Bear Advanced Exploration Project Project Definition Document, dated December 2022 by WSP E&I Canada Limited (WSP), is a password-protected document from which its content cannot be extracted or copied for detailed evaluation and reinterpretation.

In the Preface of this document, WSP states,

> "The Project as described in this document is subject to change as engineering progresses, in response to feedback from government agencies, Indigenous communities and stakeholders, as well as constraints not currently known, that are identified by ongoing environmental baseline and engineering works, and Indigenous consultation and engagement."

No new or updated Project Definition could be located and thus this version from December 2022 is reviewed here from the perspective of ML-ARD and potential water contamination.

Section 1.3 explains the objective of the proposed Advanced Exploration and its key activities:

> "The objective of this Project is to obtain additional information on the known mineralized zones (LP Fault, Limb Zone and Hinge Zone; Figure 1-3) through underground drilling, and to extract a bulk ore sample of up to 60,000 tonne (t) by underground mining methods. Extraction of a bulk sample allows the testing of representative areas of the mineralization off site, in order to gain a better understanding of the geology of the mineralized zones including, grade, structural controls on the mineralization, continuity, mining dilution, optical sorter performance and metallurgical recoveries. This information will support the assessment and development of a viable commercial production scenario.
>
> "The Project will also support future engineering designs by improving knowledge of key factors (ground conditions, water inflows, costs, labor, etc.). It will also improve the knowledge base to increase the confidence in environmental predictions associated with the proposed underground mine and to a lesser extent open pit mine.
>
> "Key Project activities are provided below:
> - Establish portal(s) and decline(s) to provide access underground in order to establish required underground workings
> - Develop drill platforms off the decline to facilitate efficient underground drilling of the known mineralized zones at depth
> - Extract up to 60,000 t of ore (bulk) sample from test stopes and drifts in the mineralized zones
> - Transport the ore to surface along the decline(s) by truck for crushing, sorting and sampling; samples will transported off site by highway truck for test processing
> - Mine rock that must be removed from the underground workings in order to provide access to the ore will be brought to surface by truck and will be stored in stockpile(s) unless appropriate for use as a construction material on site
> - Additional activities on surface and underground, such as environmental management."

These quotations raise several concerns as explained next.

Section 1.4 "Consultation to Date" with First Nations mentions Wabauskang First Nation (WFN) and Lac Seul First Nation (LSFN) in several places including an Exploration Accommodation Agreement. In contrast, Grassy Narrows First Nation (GNFN) in mentioned only twice, including where the Ontario Ministry of Mines instructed Kinross Gold to include GNFN in notifications of significant updates on exploration works. Later, Section 7.4.1 adds,

> "On September 29, 2022, the Company communicated its interest in an introductory meeting to GNFN, who respectfully declined the offer."

Section 1.5 on "Involvement of Federal Agencies" in this Project Definition starts by saying "Not currently applicable". Then it clarifies:

> "No Federal government departments or agencies are expected to grant Federal land or providing financial support to the project (include indirect funding support, such as for infrastructure and training). There is the potential that Federal departments may be required to provide environmental approvals or authorizations (see Section 7.3.1)."

Federal agencies like Fisheries and Oceans Canada will very likely be involved in authorizations as the Great Bear Project intends to discharge toxic water including from its advanced-exploration treatment plant into fish-bearing waters and fish habitat as "mixing zones" requiring authorizations. This is discussed further in Section 11 of this MDAG review.

Section 5.1.1 on Existing / Previous Development, Operations and Facilities says:

> "The first exploration work documented by Geology Ontario on the Property dates from 1944. Prior to acquisition by Great Bear Resources Ltd. in 2017, 176 diamond drillholes had been completed totalling 32,602.8 metres (m).... As of October 2022, there has been over 500,000 m of diamond drilling on the Property."

For understanding how groundwater might move during and after proposed Advanced Exploration, these hundreds of drillholes more than 500 km in total length create very permeable pathways for subsurface water to travel long distances quickly, in violation of normal hydrogeologic principles like hydraulic gradients and hydraulic conductivities. This is not acknowledged in other Great Bear documents, as explained in sections of this MDAG review such as Sections 6 and 9.2.

Section 5.1.3 on Geology and Mineralogy says:

> "The Property lies locally within a regional northwest-southeast trending belt of metavolcanic and metasedimentary rocks, bound by intrusive batholiths (see Figure 5-1). The Project is targeting gold mineralization, currently identified within three mineralized zones (see Figure 1-3):
>
> - LP Fault Zone, disseminated gold within high strain
> - Limb Zone (previously known as the Dixie Limb), silica-sulphide replacement
> - Hinge Zone, quartz veining."

The 2009 federal ML-ARD Prediction Manual (Price, 2009) shows that the ML-ARD and potential contamination from each of these zones requires separate ML-ARD evaluations. However, the proposed underground drifts are from a limited area of the ore zones, contrary to a statement that Advanced Exploration is needed to check "the continuity of underground access gold deposits" (see below).

Section 5.1.4 on Geochemical and Geotechnical Considerations states:

> "Geochemical characterization work has been initiated in order to support potential future development, including meeting the requirements of the Mine Rehabilitation Code for a future Advanced Exploration Closure Plan. Ongoing work include static testing (acid base accounting, short-term leaching), mineralogy and metal content. Humidity cells and rain barrel tests are also proposed. The conservative [worst-case] assumption pending results of the comprehensive testing program, is that ore and mine rock is potentially acid generating. This assumption will be amended on receipt of the pending test results and further assessment."

This worst-case assumption (incorrectly stated as "potentially acid generating" in comparison to the federal ML-ARD Prediction Manual) that all ore and mine rock will release ML-ARD could still be the case now, despite recent statements to the contrary (see the sections below in this review). This is because important ML-ARD work has not been completed and then certified by a qualified professional.

Section 5.1.4 also describes the overburden at the Project, which requires ML-ARD assessment equal to those of waste rock and ore according to the federal ML-ARD Prediction Manual and Ontario Regulation 240/00.

> "At the northwest portion of the Property, surficial soils are glaciofluvial in origin, consisting of sands and gravels. In the central portion of the Property, the surficial soils are described as deep-water deposits comprised of laminated to varved clay, silt and fine sand (Natural Resources Canada, 1996). Based on current exploration drilling information, overburden thickness at the Property is expected to range between 0 to 40 m. There are limited bedrock exposures within the Project area. Overburden encountered to date is a mix of sand, gravel and clay; however zones of soft sensitive clays may be encountered. An extensive geotechnical drilling program is currently underway on the Property to further investigate these and other aspects."

Section 5.1.5 on Proposed Mining Activities contains many important details such as:

> "There is no production mining proposed for the site." [MDAG Note: This appears to be a play on words because significant mining for several years is in fact proposed and Section 5.1.5 is specifically entitled "Proposed Mining Activities"; see my comments below on Section 5.1.8]. This Project includes use of underground mining methods to obtain a bulk sample of up to 60,000 t. The work is to be initiated in 2023, pending consultation, regulatory approvals and a corporate decision to proceed."

Kinross Gold further explained details of the proposed Advanced Exploration in Section 5.1.5:

> "The goal of the advanced exploration program (and ongoing exploration drilling from surface), is to collect additional information to support a decision on whether to proceed to develop a mine and to support engineering design. The advanced exploration bulk ore sample will be trucked off site over the existing Provincial road network to an existing mineral testing facility. No onsite processing is proposed.
>
> "GBR proposes to collar one or two portals from surface (approximately 6 m by 6 m) and to develop associated decline ramp(s) of approximately the same dimension. Secondary

egress and ventilation may be provided through a raise. The ramp is projected to extend to a vertical depth of approximately 600 m below surface and length of approximately 9,000 m during the Project. A preliminary long-section and plan view of the advanced exploration underground workings showing the preferred portal and raise location is provided in Figure 5-2 and Figure 5-3. The ramp is designed to provide access to the investigation areas, promote efficient truck haulage and reduce ventilation losses. Personnel will access the underground workings by means of the ramp. A shaft is not proposed for the Project.

"A bulk sample will be extracted from underground workings developed from the ramp(s) using conventional drilling and blasting using explosives, from several locations within the deposit. Blasting is proposed to use prepackaged and bulk explosive products....

"The objective of this Project is to obtain additional information on the known mineralized zones (LP Fault, Limb Zone and Hinge Zone; see Figure 1-3) through underground drilling and extraction of a bulk ore sample. Extraction of bulk sample allows testing of representative areas of the mineralization in order to gain a better understanding of the geology of the mineralized zones including, grade, structural controls on the mineralization, continuity, mining dilution, optical sorter performance, crushing and grinding properties and metallurgical recoveries to support development of a viable commercial production scenario.

"Industry-specific factors that were considered by GBR when establishing the size of the bulk sample include as follows:

- The proposed bulk sample is approximately 1% of the currently defined mineralized envelope and is consistent with other Ontario advanced exploration projects, such as the Timmins West Project (100,000 t), Sugar Zone Project (70,000 t) and Upper Beaver Project (60,000 t)
- Representative bulk samples extracted using realistic mining methods that help to prove the continuity of underground access gold deposits are very important to potential financiers
- National Instrument 43-101 resource definition and economic modeling standards are becoming more stringent to satisfy stricter due diligence standards imposed by industry and the investment community, often requiring bulk samples to validate and refine resource models prior to production decisions."

The problem with these details is that the three reasons given by Kinross Gold do not justify the 60,000 t bulk sample nor the proposed locations for the removal of the bulk sample. For example, the figure shows that most of the bulk sample will be taken from two laterally-limited areas. As a result, most of the ore from northwest to southeast will not be sampled. This is not consistent with proving "the continuity of underground access gold deposits".

Section 5.1.8 on Project Duration and Rate of Mining shows that Underground Development will take place across more than four years "on a continuous (24-hour) basis" and the Bulk Sample will be collected across roughly 2.5 years. These details plus the two 6x6 m portals show this is not typical Advanced Exploration to determine if future mining might be justified, but this is the first phase of mining.

Section 5.3.8 Buildings and Large Facilities includes Table 5.2 "Primary Buildings and Facilities on Surface". "Mine Rock Stockpiles (2)" has an approximate scale of 1,000,000 t, although it is not clear on whether this is maximum capacity or expected capacity. This is only clarified later under Section 5.4.3 (see below) which is the only description of the volume of disturbed waste rock (1,000,000 t) left on site simply to obtain 60,000 t of ore (a ratio of 17:1). This implies a large percentage of waste rock will be mined during Advanced Exploration, which further supports the view that Advanced Exploration would be the first phase of mining.

Remarkably, the various ponds listed in Table 5.2 are only described as lateral areas and do not provide depths and volumes, precluding a discussion of mass balances and spills due to extreme weather events and failures of the treatment plant. Also, the total catchment of this proposed exploration site is not provided despite all its runoff and infiltration requiring routine monitoring and treatment as needed. These are serious omissions. These omissions continue in the perhaps-draft Detailed Project Description, reviewed in Section 10 below.

Despite 60,000 t of ore being mentioned many times in this Project Definition, Section 5.4.3 "Stockpiles" is the only section of this Project Definition that mentions the substantially greater amount of waste rock with ML-ARD potential:

> "It is estimated that a total quantity of approximately 1,000,000 t of mine rock will be generated and stockpiled during the Project."

Additionally:

> "A stockpile of up to 100,000 m^3 [of overburden] is proposed", which likely means about an additional 200,000 t of disturbed overburden.

Notably, less than a year later, documents (see the later sections of this MDAG review below) have increased the overburden to ~400,000 t with no clear explanation for it.

Overburden stockpiles at minesites around Canada have released significant ML-ARD, which is why they are specifically mentioned and referenced through the Ontario Mining Act, but this Project Definition fails to recognize this. Later Kinross Gold documents fail to show the overburden stockpile and fail to show its runoff reporting to ML-ARD treatment (e.g., the undated "AEX Site Plan - Updated.pdf" on which overburden is called "topsoil"). For example, "Memo - Reclamation Strategy - Sept 5 2023.pdf" says,

> "Runoff from the overburden stockpiles (will be monitored and treated to manage suspended solids as required and discharged)".

The undated "AEX Site Plan - Updated.pdf" does not show this. This is one of many glaring contradictions and errors among the Great Bear documents reviewed here.

The understanding of groundwater at this Project is incomplete or contradictory. Section 6.25. Says:

> "The bedrock is generally tight with some potential for limited groundwater flow in the upper fractured bedrock and a few deep structures."

However, a figure in Section 5.5.2 shows groundwater as the only source of inflowing water to the underground workings. Thus, Kinross is saying groundwater inflow is "limited" but also is the only source of this water that has to be actively pumped out of the mine. This escalates to serious errors in groundwater modelling explained in Section 9.2 below that incorrectly predicts relatively low groundwater inflow and relatively little dewatering of surface creeks and lakes.

Section 6.2.6 Air Emission Information has an important omission concerning ML-ARD, environmental impacts, and cumulative effects. This section simply says,

> "A meteorological station has been established on the site, and baseline air quality and sound data is being collected. Based on a review of current Project, air emissions are anticipated to be limited and no offsite impacts are predicted. A management plan will be established to mitigated dust from materials movement and traffic on gravel roads."

However, hundreds of thousands of tonnes of blasted waste rock plus disturbed overburden will remain on site in piles up to 30 m high, likely in perpetuity after Advanced Exploration. This contaminated, blasted, and disturbed materials can release ML-ARD contaminated dust that can be carried into the surrounding environment where it can affect and degrade water quality, soil quality, vegetation, microbes, fish, and animals. As explained in Section 8 of this MDAG review, this invalidates the fugitive dust study for the Great Bear Project.

In summary of this password-protected Project Definition Document of December 2022, sufficient details and omissions are present to be very concerned about ML-ARD and water-quality degradation during and after the relatively large, at-least-four-years-long proposed Advanced Exploration that would be essentially a first phase of mining at Great Bear. These concerns carry over to the proposed mining. Although this document is not marked as "draft" and is thus final, it contains many details contradicted by later documents as explained in later sections of this MDAG review. Thus, it is not possible to know exactly what is proposed for Advanced Exploration and thus to know reliably how bad the environmental problems and impacts could be.

3. Geochemical Characterization Workplan (January 9, 2023)

This very short, three-page summary of ML-ARD "geochemical characterization", apparently issued in January 2023 by WSP, does not provide much information to review and comment on since it is only a "Workplan". However, later documents show this Workplan was not followed.

Under "Purpose of the 2023 Program", it says:

> "Samples that have been or will be tested as part of the geochemistry program include drill core (representing mine rock), overburden, and synthetic tailings generated from metallurgical test programs conducted in the laboratory. Related water quality modelling will be undertaken in 2023, focusing on the proposed Advanced Exploration (AEX) phase. Additional water quality modelling, representing the overall Project, will be undertaken at a later date."

As explained below, this Workplan is not sufficiently thorough and complete under the 2009 federal ML-ARD Prediction Manual (Price, 2009) to justify water-quality modelling and its conclusions. In any case, it is now April 2024 and no verified modelling results from 2023 have been found.

Under "Mine Rock Static Testing", this Workplan states,

> "A mine rock characterization program was initiated in 2022. A total of approximately 300 samples of drill core were collected for this purpose as part of field work in 2022. Drill core samples were obtained from a variety of locations and depths around the deposit, including rock in the vicinity of the proposed open pit and underground developments, along with the proposed AEX volume. Samples of all major rock types were collected. The purpose of this work is to evaluate the ML/ARD potential of the rock and help determine how mine rock may need to be managed.... Testwork is underway and results will be available in the first quarter (Q1) of 2023."

However, nine months later in September 2023, the Reclamation Strategy (see the next section of this MDAG review) mentions only 96 samples that are only "proximal" and thus not necessarily representative of rock to be removed for Advanced Exploration or proposed mining. Perhaps the other 200 samples are not relevant for Advanced Exploration and proposed mining, but then because they are "proximal" it is possible that the 96 samples are not relevant either.

Under "Mine Rock Static Testing", it says

> "All samples will be tested for Acid Base Accounting (ABA) parameters (that includes paste pH, sulphur content and speciation, and Neutralization Potential content and form) and elemental content analysis (aqua regia digestion and ICP analysis). Some of the samples will be subjected to more detailed static tests including the Shake Flask Extraction (SFE) test, Net Acid Generation (NAG) test, and Rietveld X-Ray Diffraction. Testwork is underway and results will be available in the first quarter (Q1) of 2023."

This is insufficient detail to ensure the correct tests are being done. In fact, "aqua regia" is a partial digestion that detects only part of the heavy metals and other elements in a sample, and thus is not acceptable for most ML-ARD work including comparisons to total crustal abundances.

Also, the September 2023 Reclamation Strategy (see the next section) mentions the results of 96 core samples, without stating which methods were used and what the analytical results were. All this information "will be available in the first quarter (Q1) of 2023", but more than a year later the information is not available as qualified-professional-certified results and interpretations.

Under "Mine Rock Kinetic Testing Programs", it says:

> "Kinetic tests are used to assess how a material responds to oxidation / weathering processes over time, and are used to estimate the time until samples may start to produce acidity and the rates at which the samples release metals. Several mine rock kinetic testing programs will be conducted in 2023, including a program conducted in the laboratory (humidity cell tests) and a program conducted in the field (field leach barrel tests).
>
> • The humidity cell test program will be initiated in the laboratory in 2023. Ten tests are currently planned and the specific number of tests will be confirmed following receipt of the static testing results. Samples to be tested will include key mine rock materials with a risk for ML/ARD along with test samples that are representative of typical Project mine rock. Initial reporting on the humidity cell tests will be available in Q4 2023."
>
> • A field leach barrel program will be initiated in the spring of 2023. Ten tests are currently planned but the specific number of tests will be confirmed following receipt of the static testing results. The objective of this program is to evaluate rates of sulphide oxidation and metal release under field conditions. This information will be integrated with the results of ongoing laboratory humidity cell tests to evaluate lag times to acid onset and metal release from mine rock. The tests will be routinely monitored throughout the open water season in 2023. Initial reporting on the field leach barrel program will be available in Q4 2023."

It is now April 2024. Where are the progress reports "available in Q4 2023"? In any case, these tests take at least one year, and often longer, to complete according to the federal ML-ARD Prediction Manual (Price, 2009). Thus, reliable and professionally certified results will not likely be available until late 2024 or 2025 at the earliest.

Under "Overburden Characterization", it says:

> "A preliminary geochemical characterization program for overburden is underway. Thirty samples of the various types of overburden present around the property were collected as part of field work conducted in 2022. Samples were submitted to the laboratory for static testing (ABA and elemental content) and a subset of samples were selected for more detailed static tests. Results will be available in Q2 2023."

Strangely, in the September 2023 Reclamation Strategy (see next section), the preliminary results are mentioned for mine rock but not for overburden. This is important because this Project Definition estimates there will be about 200,000 tonnes of overburden disturbed (with recent documents less than a year later saying ~400,000 t). This is about three times more overburden than the ore being mined as a bulk sample. On average around Canada, about half of overburden at mineral deposits has significant ML-ARD potential, so there is a significant risk that Great Bear overburden will devastate water quality on, beneath, and around the site.

Under "Mine Water Quality Estimates", this Workplan states:

> "Mine water quality estimates for the AEX phase will be prepared in Q1 2023. Modelling will be conducted via mass balance approaches and will be supported by the AEX site water balance and available geochemistry data. The model results will be used to ensure that site water management needs are identified and addressed. Additional water quality modelling, representing the overall Project, will be undertaken at a later date as the project advances."

Mine-water mass balances are not often representative of leachates from sulphide-bearing rock and overburden as found at the Great Bear Project. There is no justification here for mass-balance modelling and its results could be irrelevant for Advanced Exploration as well as proposed mining. This approach should be examined in detail including the data on which it is based once qualified-professional-certified documents become available.

Under "Technical Data Collection Methodologies", it says:

> "The approach and methodology for the geochemistry programs were based on the requirements described under the Ontario Mining Act; namely guidance found within the documents DRAFT Guidelines and Recommended Methods for the Prediction of Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (Price 1997), and Policy for Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (MEM 1998). Additional guidance was provided by the reference document Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND 2009), which represents best practice and industry standard approaches and methodologies for ML/ARD sampling and characterization in Canada."

In fact, this is wrong. The Ontario Mining Act states:

> "The sampling program shall be conducted by a person who is qualified in Ontario … in accordance with a report prepared by William A. Price on behalf of the [federal] Mine Environment Neutral Drainage (MEND) program, entitled "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials", MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..."

Therefore, for the Great Bear Project, "[t]he approach and methodology for the geochemistry programs were based on" 1997 and 1998 British Columbia documents with only "guidance" from the federal Prediction Manual. In reality, the approach and methodology are required under the Act to be based fully on the 2009 600-page federal Prediction Manual, which instead was only used for "additional guidance". The 1997 and 1998 BC documents (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997) provided relatively little detailed instructions compared with the federal Prediction Manual, so the Great Bear ML-ARD testwork started off as likely insufficient under the Prediction Manual and would have to be expanded.

Under "Field and Laboratory Work Timing", it says:

> "Some field and laboratory work associated with the geochemical characterization programs was conducted in 2022 as described in the previous sections. Additional lab work is planned for 2023 as outlined above. Field work will be conducted in 2023 to construct the Field Leach Barrel tests and monitor and collect leachate from the tests. Reporting for the various programs will be available through 2023 as described above."

I have not yet seen this reporting from 2023 and am not aware if it has in fact been reported and

certified in 2023.

In summary, problems encountered in this January 2023 Geochemical Characterization Workplan include:

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross wants to proceed with Advanced Exploration.

- All that is available now is 96 rock core analyses according to the September 2023 Reclamation Summary (see below), which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". In any case, the 96 samples were not collected and analyzed as required under the Ontario Mining Act (see next bullet). Thus, Kinross Gold and WSP are guessing on how bad the contamination will be, but admit that some of it will be bad, and are likely years away from completing the ML-ARD work required under the Ontario Mining Act and its Regulation 240/00 (Mine Development and Closure under Part VII Of the Act).

- The stated approach and methodology used for Advanced Exploration is "based on the requirements" of two British Columbia documents from 1997-1998 (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997). In reality, the Ontario Mining Act says the approach and methodology must be based on the 2009 federal Prediction Manual, not just as "guidance" as Great Bear has done. Thus, the work for Advanced Exploration to date does not meet the Ontario Mining Act through Regulation 240/00 and does not meet the 2009 federal ML-ARD Prediction Manual (Price, 2009).

- Even if this Geochemical Characterization Workplan was applicable and consistent with the 2009 federal ML-ARD Prediction Manual, such work requires at least 2 to 3 years to obtain all required information and interpretations. Thus, perhaps in 2025 or some year after there might be sufficient ML-ARD for Advanced Exploration, but not any time soon.

4. Great Bear Advanced Exploration Program Reclamation Strategy (September 2023)

The Introduction of this document explains:

> "This memorandum was prepared to summarize the reclamation strategy for the AEX [Advanced Exploration] Program. The regulatory Closure Plan which will be filed with the Ontario Ministry of Mines is currently being developed. The purpose of this memorandum is to seek input from Indigenous communities regarding the proposed closure strategy for the AEX Program."

Thus, this memo is only to "summarize" the reclamation strategy in order to "seek input from Indigenous communities". As shown below, this summary is insufficient for Grassy Narrows First Nation to provide input and this reclamation "summary" in fact already reveals errors and misconceptions.

Section 2 entitled Project Information lists "major components" for Advanced Exploration. For tonnages and sizes, only the ore is mentioned and it will be shipped offsite. So there is no overall summary of areas, volumes, and heights of waste and disturbed materials remaining on site and requiring careful reclamation. This is important, because there will be at least 17 tonnes of mine waste rock generated for each 1 tonne of ore (see Sections 2 and 10 of this MDAG review), which is a substantial ore:waste ratio and one that requires intensive efforts to protect the surrounding environment. There would also be ~7 tonnes of overburden mined for each 1 tonne of ore, which increased through 2023 from an initial ~3:1 ratio.

Therefore, this Reclamation Strategy does not sufficiently protect the environment due to the lack of sufficient data, which is replaced by information that at best "suggests". The decision to mine a huge bulk sample of ore worth tens of millions of dollars, likely to offset exploration costs, has not been based on suggestions, so why are associated reclamation and environmental protection based on suggestions?

There is no explanation in this or other documents on why an underground bulk sample requires the destruction of surface vegetation and shallow soils to remove a relatively enormous volume of 400,000 tonnes of overburden (the most recent estimate, which had been increasing). Additionally, 96 ML-ARD samples are mentioned for rock "proximal" to the underground workings, but there is no mention of the 30 samples of overburden also tested for ML-ARD potential.

Because roughly half of overburden stockpiles at sites similar to Great Bear have significant ML-ARD potential, the Great Bear overburden should be assumed to have the same strong potential for water contamination and ARD (called "PAG" in this document) unless proven otherwise. It is alarming that Kinross Gold is assuming 100% of the overburden is environmentally benign.

Figure 2 of this Reclamation Strategy shows an unlined overburden stockpile where its seepage can contaminate local water and soil, and Figure 3 shows the overburden runoff and seepage is completely ignored. This serious omission can also be seen in Section 2.3 which ignores contaminant potential from overburden by simply addressing surface runoff and not subsurface

seepage and groundwater:

> "Runoff from the overburden stockpiles (will be monitored and treated to manage suspended solids as required and discharged)"

Section 2.1 on Underground Mining Methods Summary does not describe advanced exploration where a bulk sample of several tonnes is obtained and tested. Instead, Section 2.1 describes an initial four-year phase of mining of more than 1 million tonnes of waste rock and 200,000 tonnes (more recently, ~400,000 t) of overburden to obtain only 60,000 tonnes of ore worth tens of millions of dollars. In reality, four years of this type of advanced exploration is essentially being used as the first phase of the underground mine plan so that there is relatively little delay to start mining should the project be approved.

In the Project Definition (see Section 2 of this MDAG review), Kinross Gold provided three reasons for a relatively huge bulk sample along with 17 times more waste rock and now 7 times more overburden. However, as explained above, these reasons do not make sense. For example, Kinross says that bulk samples help to prove the continuity of underground access gold deposits and are very important to potential financiers. Yet, most of the proposed underground workings are focussed into two small lateral areas and not throughout the ore zone "to prove the continuity".

In Section 2.2 on Geochemistry Summary, it says:

> "The sampling approach and testing methods for the preliminary geochemical assessment are based on the requirements described under the Ontario Mining Act, namely guidance found within the DRAFT Guidelines and Recommended Methods for the Prediction of Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (MEM 1998)."

This same error occurs in the January 2023 Geochemical Characterization Workplan. The Ontario Mining Act through its Regulation 240/00 does not mention the 1998 British Columbia document. Instead, the relevant wording is:

> "The sampling program shall be conducted by a person who is qualified in Ontario … in accordance with a report prepared by William A. Price on behalf of the [federal] Mine Environment Neutral Drainage (MEND) program, entitled "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials", MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..."

Page P-24 of this 600-page federal Prediction Manual specified by the Ontario Regulation 240/00 says, "Major technical assistance was provided by Kevin Morin (Mine[site] Drainage Assessment Group)... and Kevin Morin provided major editorial assistance." Therefore, for the Great Bear Project, I can attest that "[t]he sampling approach and testing methods" are based on the wrong document.

Based on the 2009 federal Prediction Manual required by Regulation 240/00, the proposed ML-ARD work "in progress" is not sufficient, likely because the Manual was used by Kinross Gold only as "[a]dditional guidance" instead of a required document. This is easily seen in words like "preliminary geochemical assessment" and "initial evaluation". The ML-ARD predictions and information are the main basis for design of water treatment and for reclamation/closure. Thus, it is not acceptable for treatment and closure to be based on "preliminary" and "initial" information.

This can lead to misleading impact assessments and receiving-environment effects.

There are already errors in the Great Bear ML-ARD work as found in this Reclamation Strategy. These range from an incorrect definitions of the fundamental acronyms of "PAG" and "NPAG", to major problems with samples collected to date. For ML-ARD, all that is mentioned as of September 2023 is 96 rock-core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be mined during Advanced Exploration, but only "proximal" which could also mean "very different". Some percentage of this proximal rock, such as 50% to 67%, is considered not to have much ML-ARD potential based on "preliminary" data, but that is unreliable or wrong.

Kinross Gold is guessing on how bad the ML-ARD contamination will be, and admits some of it will be bad. However, it is likely years away from completing the appropriate ML-ARD work required under the Ontario Mining Act and Regulation 240/00, including the federal ML-ARD Prediction Manual (Price, 2009).

Section 2.4 of this Reclamation Strategy on Closure Objectives says:

> "The primary objective of closure is to rehabilitate the area to a long-term safe and sustainable state that considers the desires of local Indigenous land users to the extent practical (such as post closure land uses) by promoting vegetation communities that support habitat for local species diversity and aquatic habitat that will support healthy fish populations. The purpose of this memorandum is to seek input from indigenous communities regarding end land uses and closure concepts."

It is remarkable that Kinross Gold considers leaving "NPAG" rock perhaps with a cover of 0.3 m of potentially contaminated overburden, plus a large amount of stockpiled overburden at the surface, to be a "long-term safe and sustainable state...". To the contrary, this reclamation strategy can result in perpetual water treatment. A cover over "NPAG" rock does not stop ML and contaminated effluent, which could instead require perpetual water treatment. The closure plan and its estimated cost of only ~$10 million would not pay for this.

Section 3 on Progressive Rehabilitation Measures says:

> "Mine rock will be moved underground during the program as needed for use as road material, and potentially as backfill in underground areas for stability."

This issue arises later where "PAG" rock is proposed to be moved underground after mining of the bulk sample and the many underground workings. The seriously major problem here is that "PAG" rock can release relatively enormous amounts of heavy metals and other elements as it is flooded and submerged. This can create a toxic "soup" of underground water, worse than any seen at the surface, that eventually flows out into the surrounding environment and groundwater system. This would likely require long-term pump-and-treat remediation of the surrounding groundwater. Such pump-and-treat remediation is not included or costed in the ~$10 million total closure costs, and would likely cost much more than $10 million itself.

As part of closure, Section 5.1 says:

> "The portals will be backfilled with NPAG rockfill."

Because this rock will probably be an ML concern, including leaching heavy metals and other elements, backfilling the portals with this NPAG rock that will remain partially exposed and oxidizing will lead to perpetual ongoing water contamination. Adding to this contamination will be backfilled oxidized-and-contaminated PAG material that will likely release relatively large amounts of heavy metal and other elements. Contaminated water from this PAG material, backfilled into the underground workings and partially flooded to the maximum level, and from the NPAG material plugging the portals, would start flowing out of the mine area and into the surrounding groundwater system unless there is perpetual collection and treatment.

Section 5.6 on Soils Testing mistakenly says:

> "The primary soil contamination that could be expected from the AEX activities would result from the use / spillage of petroleum / diesel fuels. A soil sampling plan will be developed at the time of closure to evaluate potential hydrocarbon or chemical contamination, as appropriate."

In reality, the primary soil contamination would likely be from the elevated levels of heavy metals and other elements in wind-blown fugitive dust (see Section 8 of this MDAG review). This dust would come from the PAG and NPAG blasted-rock stockpiles, from the overburden stockpile(s), and from mine roads and building foundations made of the blasted rock and overburden.

Section 5.7 of this Reclamation Strategy says:

> "The primary long term closure concern with respect to the mine rock stockpiles is acid rock drainage and metals leaching. Preliminary geochemical investigations suggest that up to approximately 35% of the AEX mine rock could be PAG, as discussed in Section 2.2. During the AEX Program, the PAG and NPAG mine rock will be segregated in accordance with the AEX Mine Waste Management Plan, which is currently being developed at the time this document was prepared."

"Preliminary geochemical investigations suggest that..." is not acceptable for design of the waste-rock piles and the treatment system. Preliminary geochemical investigations can be seriously wrong and substantially underestimate contamination from the rock and overburden.

Section 5.7 also says:

> "It is anticipated that up to 127,200 m^3 of PAG mine rock will be stockpiled at the AEX Program and will need to be appropriately rehabilitated either progressively or at closure."

The closure costs from the Program Closure Plan (see Section 5 of this MDAG review below) show it will cost $30.00 per m^3 to relocate the PAG rock back into the underground workings, where it would then contaminate the underground water that will eventually flow into the environment. This would be a total cost of $3,816,000. However, Table 12-1 from the Program Closure Plan (issued two months after this Reclamation Strategy) estimates PAG rock higher at 191,000 m^3 (a remarkable 50% more) costing $5,730,000.

Section 5.7 also says:

> "The NPAG Stockpile footprint may be covered with up to 0.5 m of overburden and seeded for revegetation. Additional cover depth is provided overlying the NPAG Stockpile to account for potential losses to void spaces in the mine rock. It is anticipated that the overburden material will fill in the void spaces and support revegetation."

However, the overburden could have ML-ARD potential, and thus would not support vegetation but instead kill vegetation.

In summary of the Reclamation Strategy from September 2023,

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross Gold wants to proceed with Advanced Exploration.

- All that is available now is 96 core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". Also, 30 samples of overburden, which is intended to be left on surface and used for reclamation, were collected yet the results are not reported although there is ~50% probability that the overburden will release ML-ARD and thus be toxic. Kinross Gold and WSP are guessing how bad the contamination will be, but admit that some of it will be bad. They are likely years away from completing the ML-ARD work required under the Ontario Mining Act and its Regulation 240/00, because the work for Great Bear was not initially stated as consistent with Regulation 240/00. Even the definitions of ML-ARD acronyms used for the Great Bear Project are not correct according to the federal Manual specified by Regulation 240/00, which is additional evidence the Prediction Manual is not being followed.

- The bad ML-ARD rock appears to be associated with "rapid acid generation" according to the Program Closure Plan (reviewed in the next section below). This is an incorrect explanation of the phenomenon, but shows that the bad water quality will start coming out of the disturbed rock, including the underground mine walls, very quickly after initial disturbance. Informally, this is called "lag time" to ML-ARD, but most of the ML-ARD work has not yet been done to quantitatively estimate the lag time beyond "rapid". This contaminating rock will be stored on surface and possibly only later, likely after the lag time, some might be taken underground. When it contacts water underground as the workings partially flood and submerge, it will quickly release more contamination. This means the underground water moving into the surrounding groundwater system, and surface overflow if any, would have to be monitored and likely be treated for many years or in perpetuity after Advanced Exploration.

5. Program Closure Plan, Draft for Indigenous Review (November 2023)

This password-protected draft document for Advanced Exploration is only "for Indigenous review". This is odd to me since it is Kinross Gold's responsibility to design and justify the closure plan through certified professionals, rather than submit a draft to see if any First Nations notice the weaknesses and problems explained below.

In fact, since this draft report it is password protected, none of its content can be extracted for detailed re-interpretation and review. Thus, Kinross Gold is limiting the "Indigenous review" it is seeking.

In Table 5-3 entitled Approximate Mine Rock and Overburden Volume and Production Schedule in Section 5.7 on Mineral Materials Management, the total waste rock remains around 1,060,000 t relative to past documents (see the sections of this MDAG review above).

However, overburden has risen remarkably from past documents to "~170,400 m^3", expressed as m^3 instead of tonnes like the waste rock. It would be ~350,000 to ~400,000 tonnes of overburden. The overburden's ML-ARD status and its impact on water quality are poorly defined. This means that overburden at Great Bear becomes an environmental danger capable of substantial environmental impacts not currently identified or estimated.

Table 5-4 contains Preliminary Threshold Criteria for Segregation the AEX Program Mine Rock. The criteria for "PAG" do not say whether the criteria are "AND" or "OR", which is a huge difference and serious omission. Thus, ML-ARD is clearly still not reliably estimated, predicted, and understood at the Great Bear Project as of November 2023.

The text in Section 5.7.2 alarmingly says,

> "A preliminary sulphur threshold (TS) of 0.15% has also been proposed to differentiate between PAG rock and NPAG rock. The proposed threshold values are generally accepted as industry best practices in the absence of a site specific geochemical value."

No, 0.15%S is not "industry best practices". Quebec uses ~0.05%S and other provinces have not established a minimum value because technically there is no minimum value. Furthermore, it is rarely the sulphur level alone that distinguishes "PAG" (incorrectly defined in this document as "potentially acid generating" and "NPAG" (incorrectly defined in this document as "non-potentially acid generating"). Instead, according to the federal ML-ARD Prediction Manual (Price, 2009), the amount of Effective Neutralization Potential (ENP) plays a major role, as does site-specific criteria for the ENP-to-sulphur ratio.

This is explained in detail in the 600-page federal ML-ARD Prediction Manual that this ML-ARD work for the Great Bear Project is legally supposed to follow but does not. As a result, this "preliminary sulphur threshold" is an unreliable, questionable, and uncertified attempt to proceed with the design and planning for Advanced Exploration. Insufficient reliable information is available at this time, and even Appendix A "Certifications" is missing from this document. As a professional

in ML-ARD, I want to know the certified professional(s) who created these "preliminary" criteria.

"NML" is defined in this Closure Plan as "non-metal leaching" which does not apply to any rock in the world, as all rock is capable of leaching some metals and even nonmetals. In any case, "NML" in Table 5-4 for the Great Bear Project is rarely definable by the solid-phase level of a single element like "Arsenic < 30 mg/kg", but Kinross Gold does not know this because it has not yet completed the on-site and laboratory-based kinetic tests. If leaching were dependent on solid-phase levels as believed here, then Great Bear waters would contain thousands of mg/L of aluminum and silica because most of its rock is made of those elements. But this is not the case. This is why these are called "preliminary threshold criteria" in Table 5-4, which in reality are likely wrong and nonsensical.

Section 9.16 on Watercourses and Site Drainage contains Tables 9-1 to 9-5. Tables 9-4 and 9-5 contain predictions of on-site and effluent contaminant levels only after closure, which would obviously be much less than during active exploration. However, the text does not even discuss or explain Tables 9-4 and 9-5. They appear to be "thrown in" to appear complete.

Table 9-4 contains Geochemical Source Terms, which are the predicted aqueous concentrations for all contaminants in Great Bear water caused by Advanced Exploration. In reality, there are many problems with this Table 9-4 including:

- It does not include "PAG" concentrations which will be much worse and will be present for at least four years, because this Table is intended only for closure but alarmingly does not include the likely more severe PAG contamination when it is backfilled into the underground workings.
- It assumes closure drainage from "Covered and Revegetated Area" will be instantaneously at pre-exploration "baseline water quality", which is wrong.
- It shows elements likely requiring perpetual post-closure treatment include aluminum, antimony, arsenic, and selenium.
- It does not include predictions for many potential contaminants such as manganese, magnesium, sodium, potassium, barium, hardness, alkalinity, acidity, fluoride, chloride, bismuth, chromium 6+, lithium, silicon, strontium, tellurium, thorium, tin, titanium, and zirconium.
- It does not allow for federal emerging contaminants such as platinum-group metals and tantalum.
- It is based on a report "WSP 2023f" which is the draft "WSP, 2023f. Advanced Exploration (AEX) Phase – Preliminary Water Quality Estimate Update - Draft. WSP E&I Limited, April 2023". This report is only draft and thus is unreliable and not professionally certified.

Table 9-5 contains Mine Water Pond Overflow Estimated Water Quality which apparently would be overflow off the exploration site upon closure. It raises important questions, like how does aqueous sulphate decrease from 75-100 mg/L (Table 9-4) to 18-25 mg/L (Table 9-5) in mine-water-pond overflow when there is no treatment? In any case, some predicted concentrations are likely too high to discharge to the environment like arsenic. Also, sulphate reportedly increases the methylation of mercury and other elements.

Table 12-1 is the Closure Cost Estimate. The cost for moving PAG rock back underground is set at $30.00/m^3 which is ~$15.00 /tonne. The total waste rock from Advanced Exploration is estimated at 1,060,000 t. Kinross Gold currently guesses, based on preliminary uncertified information, the waste rock will be about one-third to one-half "PAG" requiring backfilling to the underground. Therefore, the cost for this task alone is $5,000,000 to $7,500,000 based on the unverified guess, and could reach a maximum of $15,000,000. Because the current Grand Total for Closure is estimated at ~$10,000,000, the backfilling of rock is the major cost item and could cost much more than the $5,730,000 currently estimated. In turn, Total Cost could cost many millions of dollars more than currently estimated from the guessed minimal amount. Put simply, closure costs are likely grossly underestimated.

All six appendices of this Program Closure Plan are missing, including professional certifications. This is likely not an error or oversight, meaning this Program Closure Plan should not be considered reliable and dependable.

In summary of the password-protected Program Closure Plan, Draft for Indigenous Review from November 2023,

- In November 2023, the volume of overburden has approximately doubled from previous documents without an explanation. Because overburden generally has a 50% probability of releasing ML-ARD and contaminating water, overburden represents a major but unexamined threat to water quality on, around, and beneath the Great Bear exploration site.

- "Preliminary" criteria are provided for separating "PAG" and "NPAG" rock and for "NML" rock. However, these acronyms are not used in an accurate manner consistent with the 2009 federal Prediction Manual (Price, 2009) required under Regulation 240/00. The preliminary criteria are not rational based on ML-ARD science unless justified with detailed and intensive site-specific studies, which have not yet been completed and certified for the Great Bear Project.

- The potential for ML-ARD after closure is presented all the way to detailed predictions of aqueous concentrations in mg/L for on-site water and effluent to the environment only after closure. However, these predictions are not explained in any detail, are not justified, appear anomalous, and are not certified by a qualified professional. Some predictions are actually pre-exploration baseline which are erroneously assumed to be re-established immediately at closure. Furthermore, these predictions are missing more than a dozen potential contaminants.

- The "PAG" rock, which would likely create the highest contaminant concentrations, is not included in this Program Closure Plan, presumably because this "PAG" rock will be backfilled underground. However, when placed underground, this "PAG" rock will likely continue to release severe ML-ARD until submerged, at which point a relatively huge amount of accumulated contamination would be released into the underground water. After the mine is refilled to equilibrium and the minewater begins flowing into the surrounding groundwater system and through the many permeable drillholes more than 500 km long to the

environment, it will contaminate large surrounding areas. This major risk to water quality and the environment is not even mentioned in this Closure Plan, which is a major omission.

- The backfilling of "PAG" rock at closure is the largest individual cost item for closure totalling around $10 million. However, this reflects the currently minimum volume based on preliminary, unreliable information. In the worst case, which was assumed for the Great Bear Project Definition and still not disproven, total closure costs could exceed $20 million.

6. Hydrogeological Workplan (December 21, 2022)

This Workplan for 2023 says:

> "The purpose of the program will be to develop a refined hydrogeological model of the site, support groundwater model calibration and be used for long-term monitoring. The information collected in the upcoming field surveys will supplement the existing information.... Hydrogeological testing and groundwater sampling will occur at specific locations near the Project site shown in Figure 1."

However, Figure 1 of the Hydrogeologic Workplan shows a major omission which would preclude fully meeting its purpose and objectives. The currently proposed mine plan shows the "Tailings Management Facility" extending at least 2 km to the west and northwest of Tear Drop Lake. Figure 1 shows that the Tailings Management Facility and its hydrogeologic effects would extend far beyond the western limit of the monitoring wells. Thus, many more monitor wells are needed westward and northward at least to Stone Lake, Gullrock Lake, and Genessee Lake.

In summary of this Hydrogeological Workplan from December 2022, there is a major omission that would preclude a reliable and comprehensive assessment of current baseline hydrogeologic conditions and of future impacts from proposed mining. The groundwater monitoring network does not extend far enough to the west and northwest, beyond the proposed western portion of the Tailings Management Facility.

7. Surface Water Quality Workplan (December 21, 2022)

This Workplan for 2023says:

> "Baseline surface water quality work has been ongoing for the proposed Great Bear Project (the Project) since 2020. This proposed workplan for 2023 is to gather supplemental water quality data that will be used to further support long term monitoring and the development of the Project."

This Surface Water Quality Workplan provides incomplete lists of important details prefaced by "including", like "These sampling locations include..." and "Standard suite of total and dissolved metals including...". This can lead to major problems in the future if a sampling location or water-quality parameter is missing.

For example, the "Standard suite of total and dissolved metals including..." does not mention important elements like manganese, titanium, thallium, and federal emerging elements like tantalum and platinum-group elements. Therefore, Kinross Gold is risking major omissions and flaws that can arise later by not being comprehensive in its "including" lists.

In summary of this Surface Water Quality Workplan from December 2022, there are insufficient information and details to determine if appropriate work is planned and conducted. This is because important details are listed only as "including". For example, major potential contaminants like manganese and thallium are not specifically listed, but perhaps they are implicitly included? There is no way to know.

8. Fugitive Dust Best Management Practices Plan, final draft (September 2023)

Section 4.5 on Material Stockpiles in this "Final Draft" states there will be two overburden stockpiles created during Advanced Exploration, one north of the mine-rock pile and another east of the crusher area. Some Great Bear documents reviewed above and the undated "AEX Site Plan - Updated.pdf" do not show this. Because the overburden has a general 50% probability of contaminating water and because overburden is specifically listed as a site component requiring ML-ARD evaluation and potential mitigation, this contradiction on overburden stockpiles is not acceptable. It further shows that Kinross Gold's ongoing issuing of "preliminary", "initial, and "draft" documents is causing confusion inside the project itself and thus should not be approved at this time.

Section 5.1 on the Composition and Characterization of Particulate Emissions contains a major error that would grossly underestimate the geochemical contamination of soil, vegetation, water, and biota by dust, and is thus not acceptable. Section 5.1 says:

> "Fugitive dusts from roadways and stockpiles may contain trace metals which may be considered negligible as these would be similar in concentration to the background rock."

The ML-ARD studies currently underway on ore, waste rock, and overburden have already shown that some material will contain substantial solid-phase levels of many elements and will leach to some degree. This is certainly not "background rock" as assumed in this fugitive-dust study. Therefore, fugitive dust should be an important component of impact assessment for Advanced Exploration and proposed mining.

Furthermore, proposed dust suppression by watering could lead to widespread metal leaching and water-quality degradation across and around the proposed exploration site.

In summary of the final-draft Fugitive Dust Best Management Practices Plan of September 2023 for Advanced Exploration, this work is unacceptable because it grossly underestimates the potential impacts from geochemical contamination of soil, vegetation, water, and biota by dust. This work assumes the on-site sources of dust "would be similar in concentration to the background rock". This is wrong and ignores the ongoing ML-ARD assessment of ore, rock, and overburden.

9. PTTW Application for Dewatering, final draft (October 2023)

This is one of the few Great Bear documents that provide names for the qualified person writing the report, appropriately signed as "DRAFT" at this time. However, the reviewer but not the author is a P. Geo. So additional information is needed on the qualifications and certifications of the author(s). PPTW stands for "Permit To Take Water", meaning using and removing water from the Great Bear site.

9.1 Main Report

The tone of this "final draft" report for Advanced Exploration is apparent from Section 1.1 on the Purpose and Scope of This Submission. It says:
"Water takings during the AEX Program will include:

- Water pumped from the underground exploration workings (underground dewatering)
- Incidental surface water and groundwater takings, expected to occur during excavation of water management ponds.
- Direct taking from Dixie Creek (up to 250 cubic metres per day; m^3/day) to be used for dust suppression, industrial activity (e.g. in support of development pad construction and packing) and advanced exploration drill water cooling (underground drilling).

"No other takings from other area waterbodies (lakes, rivers, streams) are proposed.

"Most of the dewatering water pumped from the underground exploration workings will be directed to ponds within the AEX water management system, treated and ultimately discharged to the environment to be approved under an Environmental Compliance Approval for Industrial Sewage Works (ECA ISW)"

First, note that the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning that the actual total water withdrawal from the local water balance, as shown in Table 4-1 (discussed below), would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these values are unrealistically low (see Section 9.2 below). This major withdrawal of water, that could upset and dewater groundwater zones like aquifers and surface waterbodies like creeks and lakes, is much more extreme that numerically indicated in Section 1.1. This justifies an impact assessment on the proposed Advanced Exploration, despite this final-draft document stating:

> "The AEX Program does not meet the requirements of the Impact Assessment Act, Physical Activities Regulations. A Federal Impact Assessment is therefore not anticipated to be required."

Second, note that the quotation above states that water taken from Dixie Creek would be used for "dust suppression" among others. As explained in the previous Section 8 of this MDAG review, adding such water to ML-ARD dust from ore, rock, and overburden could seriously degrade water quality throughout the site and surrounding environment. However, this major environmental risk

is not considered or even mentioned here or in the fugitive-dust study. In fact, it is unreliably assumed to be no environmental risk at all.

Third, the discharge of up to 7,703,000 L/day of water that is only partially treated (see the details in other sections of this MDAG review like Sections 5 and 11) into any receiving environment could cause significant impacts from (1) the physical volume of the additional water and/or (2) its altered chemistry from baseline with implications on the receiving environment and cumulative effects.

Table 4-1 on Requested Water Takings shows that the requested surface-water withdrawal from Dixie Creek is 250,000 L/day and an additional 170,000 L/day from pond excavations. However, more than 10 times this amount will be removed from the groundwater system every day. The additional groundwater withdrawal is estimated at 783,000 L/day from pond excavations, 2,000,000 L/day from underground pumping, and on perhaps 30 days each year an additional 4,500,000 L/day removed as a contingency. Furthermore, as explained below for Appendix B of this PTTW document (see Section 9.2 of this MDAG review), the groundwater model incorrectly underestimates the much higher inflows that would arise during desaturation of the overburden and the rock surrounding the mine inside its "Zone of Influence".

Total water withdrawal from the existing water balance could thus likely be much more than 7,703,000 L/day relative to the Dixie Creek withdrawal of only 250,000 L/day. All this water would be taken from the existing baseline groundwater/surface-water balance which has likely reached some type of baseline equilibrium over the last thousands of years. When up to 7,703,000 L/day or more is removed from this equilibrium, there could be major disruptions to local and regional surface waters and groundwaters.

For example, a significant portion of the underground pumping of more than 6,500,000 L/day could be pulled from Dixie Creek through the underlying groundwater system. Thus, "takings" from Dixie Creek could in reality be 250,000 L/day plus substantially much more than this through groundwater. "Takings" could also come from other streams, lakes, and groundwater zones like aquifers, despite this report clearly stating, "No other takings from other area waterbodies (lakes, rivers, streams) are proposed". This statement is not reliable and could be seriously wrong.

Section 5 of this PTTW Application discusses Potential Environmental Impacts, with Section 5.2.1 specifically on Dixie Creek. There appears to be significant confusion here on the impacts of dewatering the underground workings on Dixie Creek.

Part of this confusion arises in the false thinking that baseflow coming from groundwater is simply part of the total flow in Dixie Creek. In reality, groundwater baseflow likely has a different, more stable temperature and a different water quality than the surface water flowing past the Great Bear Project. Therefore, it is important environmentally and to the benthic ecosystem to consider baseflow coming from groundwater separately from surface flow already in the creek.

Another part of this confusion on the physical impact of mine dewatering on Dixie Creek is related to which surface flow is used. Section 5.2.1 uses Average Annual Flow, Low Flow Period Average Flow (March), and Low Flow 7Q20. These show that mine dewatering will reduce flow in Dixie

Creek by only 0.2 to 2.4%. Again, these impacts would be greater because the groundwater of Appendix B (see Section 9.2 below) has underestimated the amount of underground water that has to be pumped.

Table 5-2 is more relevant for Dixie Creek, also copied as Table 7-2 in Appendix B. It shows the important, separate baseline baseflow for Dixie Creek is 2,601,000 L/day. This is predicted to be reduced by 873,000 L/day during dewatering for Advanced Exploration, although this is likely substantially underestimated by the groundwater model. Thus, much more than 34% of Dixie Creek baseflow will be taken away by the mine, which would have significant adverse effects during drought periods and on the quality of the benthic aquatic habitat. Additionally, the baseflow for Unnamed Waterbody 3 (called "Dixie Creek Tributary (TL-3)" in Appendix B) would be reduced a substantial 55%. This justifies an impact assessment for the proposed PTTW Application.

It is very important to note that this PTTW Application for Dewatering, final draft, contains and is based on critical information in its Appendices. The following comments pertain to these appendices, which in turn shows the main report is not reliable and not reasonable as a PTTW Application.

9.2 Appendix B

Appendix B of this PTTW report is a "Draft" Groundwater Modelling Report to Support PPTW Application for Underground Dewatering Final Draft. It contains a serious error in the groundwater modelling that underestimates initial groundwater inflow rates and thus dewatering pumping rates.

Table 4-1 of the main report says 3,203,000 L/day of groundwater would be removed every day, reaching up to 7,703,000 L/day on some days. Table 6-2 of this groundwater appendix says that the groundwater grid, from Genessee Lake on the west to half of Rice Lake to the east, has total groundwater inflows and outflows of ~10,000,000 L/day. If this modelling were correct, this means that roughly 32% of all groundwater in the area of the Great Bear Project will be drawn into and out of the mine on a daily basis, with up to 77% drawn into and out of the mine on some days as a contingency. However, it could well be worse as explained next. This justifies an impact assessment for the proposed PTTW Application.

If dewatering starts and continues for several years as proposed for Advanced Exploration at the Great Bear Project, and later during the expansion of proposed mining, groundwater inflow will come from two basic sources. The first, initial inflow will predominantly reflect the desaturating drainage of pores in the overburden and fractures in the rock, which will be relatively high at first and then decrease. Notably, the modelling currently shows that the overburden will eventually be virtually 100% dewatered to its base. This is called "transient conditions" and reflects the "specific yield" of the overburden and the "storage coefficient" of the rock. As this first transient inflow slows, likely years after Advanced Exploration ceases, the groundwater inflow will then come from "steady state", reflecting the hydraulic gradients and the hydraulic conductivities.

This modelling for Great Bear in Appendix B and for the PTTW Application is solely "steady state",

with no high transient inflow considered and no values for specific yields and storage coefficients even mentioned. Section 6 of Appendix B on Groundwater Model Development is clear on this:

> "Groundwater modelling was conducted for two phases: pre-mining site conditions for model calibration and mine operations conditions to predict *groundwater discharge rate to the proposed fully developed and dewatered underground mine workings* [MDAG emphasis]. These numerical groundwater flow models consider 3D *steady-state flow conditions* [MDAG emphasis] and implement an Equivalent Porous Media (EPM) approach, which is deemed sufficient for characterizing the overall groundwater flow regime at the scale of this analysis."

Thus, groundwater inflows in the years of active mining during Advanced Exploration have been clearly underestimated by considering only steady-state inflows after the proposed workings are "fully developed". Also note the ambiguous and unjustified "deemed sufficient" for the overall "EPM" modelling of groundwater at the Great Bear Project.

Table 6-3 showed that pre-mining single-value "measured interpreted" baseflows at two locations agreed with the Simulated Baseflow reflecting only long-term steady-state conditions by 14% or better. These single-value baseflows were 2,281,000 L/day and 847,000 L/day, which are less than the total groundwater that would be pumped from the mine during Advanced Exploration. Thus, a concern arises on whether baseflows could be significantly decreased by this pumping during Advanced Exploration. The main report (see comments above in Section 9.1 of this MDAG review) says the (underestimated) pumping effect would be minimal on most statistical values of flow in Dixie Creek. It is not emphasized that pumping would substantially reduce baseflow, with differing water quality and temperature than the surface water, and would be even more significant during droughts.

Figure 6-6 shows that the pre-mining Simulated Groundwater Levels were often 5 to 10 m higher than Observed Groundwater Levels, showing a strong bias towards overestimated (higher) simulated groundwater levels. It is not clear if this suggests simulated hydraulic conductivities may be too low. In any case, this problem manifests in Figure 6-7 where the simulated levels around Great Bear and Dixie Creek are typically around 9 m too high, which incorrectly and falsely indicate Dixie Creek could not be significantly dewatered during pumping because the water table is simulated to be very high. This is probably why Table 7-2 shows that the substantial yet likely underestimated partial dewatering of Dixie Creek Tributary (TL-3) and baseflow of Dixie Creek is 55% and 34%, respectively, and these dewatering percentages could be much higher if modelling were more accurate.

Of note, Table 7-1 indicates dewatering of Dixie Creek is only 1% because it uses the average annual flow that includes the sum of all storm events. It does not consider lost baseflow during dry times when aquatic life, vegetation, and water quality can be more severely degraded. Again, the simulated groundwater levels around Dixie Creek and Great Bear are often modelled around 9 m too high and thus actual dewatering of creeks and lakes could be much higher than stated in this groundwater report. In this case, Section 10 incorrectly states and underestimates based on the modelling that:

> "At the end of the AEX project, when dewatering is at its maximum, the model simulates a baseflow reduction for the Dixie Creek of 8.5% of the estimated 7Q20 (10,368 m^3/d) and 1% of the average annual flow (114,912 m^3/d), which is unlikely to change the nature of the flow

regime in the creeks."

In Section 7.1 on Groundwater Inflow Rate and Zone of Influence:

> "... the simulated long-term groundwater inflow rate into underground mine workings is 1,920 m^3/d [1,920,000 L/day]. This estimate of groundwater inflow into the fully developed mine does not consider uncertainty, seasonal variations or any loss from aquifer storage."

This simulated inflow is consistent with the estimated 2,000,000 L/day requested "taking" in the main report and in Table 8-1. However, the occasional contingency of 6,500,000 L/day which is apparently from "uncertainty, seasonal variations or any loss from aquifer storage" is relatively major. It highlights the expected variability of withdrawals and discharges of water into the surrounding environment during Advanced Exploration. Moreover, the reference to "aquifer storage" highlights the failure of the modelling to consider higher-inflow transient conditions which would be most important in the early several years of Advanced Exploration.

However, even ignoring the important high-flow transient conditions, Table 7-1 shows that the steady-state 2,000,000 L/day can be easily exceeded by non-base-case conditions like three-times-higher hydraulic conductivity of bedrock and by the water-conducting LP Shear Fault 1.

Section 7.1 explains:

> "The model-predicted Zone Of Influence (ZOI), defined here as 1 m drawdown of head in the glacial till unit is shown in Figure 7-1. The ZOI is predicted to extend about 1.2 to 2.5 km from the centre of the AEX site to surrounding environs."

Using the 1 m drawdown contour is not appropriate here, because modelled groundwater levels are already around 9 m too high and because Figures 4-9 and 4-12 show that some shallow groundwater levels can vary by 1 m naturally. Thus, the Zone of Influence could turn out to be much larger and thus affect lakes and creeks. In any case, even a 1 m decrease in groundwater level beneath a creek or lake can lead to substantial dewatering.

Figure 7-1 shows Simulated Drawdown Contours in Glacial Till. However, drawdown is only shown as a maximum of around 36 m, which is obviously not correct for dewatered drifts up to 600 m deep. Moreover, the maximum drawdown of 36 m in the overburden means most of the pores of the overburden would be primarily drained into the mine, which occurs during the ignored transient conditions.

The apparent explanation for the discrepancy between the maximum 36 m drawdown and the dewatered workings 600 m deep is that the drawdown in the bedrock is not shown, but would locally obviously be around 600 m. This 600-m drawdown would likely create a relatively huge drawdown zone in bedrock around the Advanced Exploration and the proposed mine extending for many kilometers around. This would be much larger than in the Zone of Influence in the overburden shown in Appendix B Figure 7-1. This justifies an impact assessment of this proposed dewatering since many impacts of the dewatering have been ignored or underestimated.

9.3 Appendix C and Its Several Draft Monitoring Programs

Appendix C contains draft monitoring programs. The "Working Draft" AEX ISW Groundwater Monitoring Plan, like many other Great Bear documents, ignores the overburden that likely has ML-ARD potential and can seriously contaminate water. This lack of consideration for potentially contaminating overburden can be seen in Figure 1-7 Water Management Schematic that has no mention or recognition of the overburden stockpile(s). The same is noted in Figure 1-6 of both the "Draft" ECA ISW - Advanced Exploration Surface Water Monitoring Plan Draft and the "draft" AEX ECA ISW Aquatic Resources Monitoring Plan in Appendix C.

9.4 Appendix D

Appendix D Consultation Records is missing from this file.

9.5 Summary

In summary of this PTTW (Permit To Take Water) Application for Dewatering, Final Draft, and its several important appendices from October 2023, there are alarming errors and ambiguities that should preclude approval of PTTW. These should also trigger a detailed impact assessment, which this PTTW report conversely says is not needed for Advanced Exploration at Great Bear.

In the introduction to the main PTTW report, the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning because the actual total water withdrawal from the local groundwater/surface-water balance would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these values are unrealistically low as explained here.

The errors begin with groundwater modelling that is based on long-term "steady state conditions" after the mine is "fully developed" and dewatered, and not on the correct, higher-inflow "transient conditions". Thus, inflow, pumping, and dewatering are significantly underestimated by the groundwater model and the PTTW Application. Additionally, there are problems with unrealistically low estimated effects on partial dewatering of Dixie Creek and other creeks and rivers. For example, simulated groundwater levels are modelled around 9 m higher than measured around the mine and Dixie Creek, which artificially and incorrectly prevent additional dewatering of Dixie Creek.

Groundwater levels are shown to be drawn down during dewatering to a maximum of only 36 m even though the dewatered workings will be 600 m deep. This reflects (1) nearly fully dewatering of the shallow overburden and (2) the lack of admission on the likely huge drawdown and much larger "Zone of Influence" in the rock beneath the overburden.

Baseflows into Dixie Creek and other waterbodies can be critical to aquatic, benthic, and terrestrial ecosystems because of groundwater's typically different water quality and temperature compared to water already flowing at the surface. This becomes more critical during droughts when baseflow

may be the main source of surface flows. The PTTW Application ignores the fact that more than 34 to 55% of existing baseflow would be lost during Advanced Exploration. It instead points out that the loss to groundwater would be only 2.4% and less of total flow depending on the chosen surface-flow statistic.

Overburden is routinely ignored in this PTTW document and its appendices, despite the proposed hundreds of thousands of tonnes of overburden likely having at least some ML-ARD potential and capacity to degrade water quality. In fact, some of the underground dewatering would be sprayed on the overburden for dust suppression, which in turn could lead to contaminated runoff across and off the site.

10. Draft (?) Detailed Project Description (November 2023)

In June 2023, Kinross Gold released the [final] Initial Project Description for the Great Bear Gold Project. Five months later, Kinross Gold issued the Detailed Project Description, where the first cover page showing "Kinross" says "DRAFT", but the second cover page for WSP E&I Canada Limited does not say "Draft".

The Kinross/WSP documents reviewed so far for proposed exploration and proposed mining are a mess with confusions over draft, preliminary, initial, and final. There is no reliable way to know what information issued by WSP and Kinross is considered final, reliable, and still applicable. In my opinion, all reviews for Great Bear should stop until Kinross Gold and WSP identify the final designs and plans for proposed exploration and proposed mining. Only then should they issue the final documents, signed and approved by qualified professionals.

Because the Initial Project Description was followed five months later by this perhaps-draft-perhaps-not-draft Detailed Project Description that apparently includes responses to Initial concerns, only the latter document is reviewed here.

10.1 Section C.3.3 Proposed Mine Facilities and Infrastructure

Section C.3.3 and Table C.1 provide a detailed list of all proposed mine facilities, many of which would be created during Advanced Exploration, which as explained above is closer to a first phase of mining. Many of the listed facilities require ML-ARD assessment including all under the headings of Underground and Open Pit Mine including mine walls and sumps, Stockpiles including overburden and waste rock, Tailings and Site Water Management including ditches, Aggregate Supply, Waste Management, Fuels and Reagents, all access roads and haul roads, all excavations and foundations for buildings, facilities, pipeline corridors, upgrades to bridge crossings, and the core shack including core-storage areas. Because these ML-ARD assessments are not completed at this time, it is prudent to conduct an impact assessment on all these components.

The Stockpiles section says:

> "Stockpiles will be created on the surface near the mine to store ore, mine rock, and overburden / organics resulting from site and mine development. Preliminary storage capacities of the stockpiles for the Project are the following, subject to revision as a result of ongoing exploration and technical studies:
>
> - Run of mine (i.e., uncrushed rock as transported from the mine) ore stockpile: approximately 0.1 to 0.5 million tonnes (Mt)
> - Low grade ore stockpile: approximately 5 to 20 Mt
> - Mine rock stockpile(s): approximately 210 Mt
> - Overburden / organics stockpile: approximately 40 Mt."

Thus, upon full mining, there would hundreds of millions of tonnes of mine waste, with most of it likely remaining on the surface and requiring perpetual maintenance. Additionally, low-grade ore

stockpiles are sometimes left on site after closure as waste-rock dumps. Because of this, some jurisdictions require financial assurances on perpetual maintenance of the low-grade dumps until/if they are processed. This should also be done for the Great Bear Project.

> " Based on the scale of the stockpiles and the environmental baseline studies which are in progress, it is expected that one or more of the Project stockpiles will overprint minor creeks which may contain fish."

Thus, there will be "overprint" impacts through destruction of fish, fish habitat, and associated water quality.

The Ore Processing section says:

> "Ore processing will entail several stages of conventional mineral processing such as grinding and classification, and cyanide leaching to separate the gold / silver from the gangue leading to production of doré bars."

Thus, the processing will add contaminants including cyanide and accelerated leaching of metals and other elements that will contaminate the water in the process, in the tailings impoundment, and in the fugitive seepage that will flow into the environment.

Also:

> "There are no sources of mercury from the ore processing."

This appears impossible because the ore rock going in, and the tailings and concentrate coming out, of ore processing should and will contain some level of mercury. The processing could even increase the solubility or leaching rate of mercury and other elements. Therefore, this appears to be an error unless Kinross Gold can prove the tailings and concentrate from the ore processing contain absolutely no mercury. This is highly unlikely if not impossible to prove.

The section on Tailings Management explains:

> "The primary by-product of ore processing is tailings. Tailings consist of ground rock and associated process effluents that result from the processing of ore. Tailings will be treated for cyanide destruction before storage. As part of the ongoing geochemistry investigations it was determined that the tailings may be potentially acid generating, Kinross is investigating the potential to desulphurize the initial tailings stream resulting in a non acid generating flotation tailings, and a smaller quantity of sulphide tailings that would be managed in a manner to mitigate their acid generating potential."

Cyanide destruction is rarely perfect and sometimes simply converts the cyanide to thiocyanide or cyanate which can then revert to cyanide after release to the environment. Because the details of Great Bear's cyanide destruction are not given, it is prudent to assess it for potential environmental impacts.

Tailings Management further says:

> "Tailings will be transferred from the processing plant to an onsite surface management facility as a slurry, or potentially as a filtered cake. A quantity of the tailings will also be sent to a paste backfill plant where they will be mixed with a binder (such as cement) to increase their strength, so that they can be returned to the underground workings to provide additional underground stability. Tailings could also potentially be stored in the open pit after mining

is complete.

Tailings paste backfill, dewatered filter-cake tailings, and the relocation and in-pit disposal of tailings each could have unique adverse impacts on water quality and this should be assessed by Kinross Gold.

> "Further detail on tailings management facility, including dam designs as applicable, will be developed as engineering progresses for the Project. The facility will be designed in accordance with all regulatory requirements including the Canadian Dam Association Dam Safety Guidelines as applicable."

Thus, the details for evaluating potential environmental impacts will not be available until "engineering progresses", which is consistent with the ML-ARD work which will not be completed for at least a few years.

Notably, this section on Tailings Management has no detailed description of water management including any water recirculation. This is a major omission that precludes a reliable assessment of impacts from how much water would be needed daily to run this proposed mine.

The section on Buildings and Yard Areas states:

"The following new permanent facilities are planned for the Project:

- Process plant and crusher / conveying system
- Mine office / dry / maintenance / wash bay complex
- Cold and warm storage buildings
- Reagent storage facilities
- General laydown areas and parking
- Additional core shack, laboratory and outbuildings
- Accommodations / camp
- Explosives storage facilities.

These will be supported by related road, piping and power infrastructure as needed."

The disturbed rock or overburden used in any of these Areas requires an ML-ARD assessment as explained in the 2009 federal ML-ARD Prediction Manual (Price, 2009).

The section on Water Management Facilities and Drainage Works explains:

> "Kinross proposes to establish an integrated water management system for the site to manage contact water from the underground mine, open pits and surface facilities. The underground mine will intercept groundwater, while the open pit will collect groundwater, runoff and direct precipitation. Mine water from the required dewatering of the underground mine and open pit, to enable mining to occur will be collected in sumps and pumped to the surface for additional management. The mine water management and treatment infrastructure developed for the AEX program is expected to be re-used at the beginning of operations and will potentially be incorporated into the overall integrated water management system for the operating mine.
>
> "Precipitation and surface runoff that comes into contact with mine-related facilities on surface will be collected in ditches and collection ponds designed. As needed, the water will be directed to the integrated water management system for treatment and discharge with

other site contact water.

> "The integrated water management system and associated effluent treatment plant will be designed and operated to ensure that effluent from the site meets all regulatory requirements and can be discharged to the environment. Effluent will be discharged to the Chukuni River a large watercourse with high assimilative capacity. This will allow continued use of the pipeline corridor established for the AEX program. The additional infrastructure required for the mine has not yet been determined."

This section on Water Management Facilities and Drainage Works does not explain the storm return periods for which the drainage works would be sized. Nor does it specify the design return period for the post-closure water management, such as the 24-hour 1-in-200-year precipitation or the Probable Maximum Flood. This is a major omission that precludes a reliable assessment of impacts from storm events that could lead to spills of contaminated site water, and thus confuses the decision on whether an impact assessment should be conducted.

Under Access and Site Roads:

> "A network of roads of will be established within the site as needed, minimizing water crossings. New roads will be constructed of aggregate or non-potentially acid generating mine rock. New major road and watercourse crossings are not expected for the Project, although minor crossings and cross drainages may be needed. The water pipeline corridor which will be developed for the AEX program, and potentially expanded with additional pipelines for the mine, includes an access road to allow for pipeline inspections, environmental monitoring and maintenance, and is expected to cross four headwater creeks / low-lying swales, likely as culverts (Figure C.1 and Figure C.2). The existing prefabricated truss bridge across Dixie Creek may be upgraded."

Any surface and subsurface disturbance including new roads require ML-ARD assessments before an impact assessment can be done according to the 2009 federal ML-ARD Prediction Manual (Price, 2009).

The Section on Aggregate Operations contains a serious error:

> "Aggregate will be required to develop the Project. The primary source of material is proposed to be *nonreactive mine rock and overburden* [MDAG emphasis] from stripping and other construction activities within the site. There are licensed commercial aggregate pits nearby (along Tuzyk's Road) that also represent a potential source of aggregate for the Project. Discussions with the owners of these aggregate facilities are planned to explore potential commercial arrangements.
>
> "New quarries for crushed rock and sand and gravel pits may be established on the Property if needed under the care and control of Kinross. Locations are not as yet known but may be situated at future development locations (such as within the tailing management area)."

Because there is no such thing as "nonreactive mine rock and overburden", then there will be no aggregate which is "required to develop the Project", which in turn literally means there can be no Great Bear Project or mine. This illustrates how Kinross Gold is submitting perhaps-draft

documents with statements intended to alleviate concerns that are instead false and misleading.

This document is not signed and certified by Qualified Professionals, so at least portions of this Detailed Project Description are more akin to Public Relations than technical accuracy. Grassy Narrows First Nation should be aware of these false statements in important documents supposed to describe accurately and reliably the proposed exploration and proposed mining of the Great Bear site. It is not prudent to decide impacts of proposed exploration and mining based on false technical statements.

10.2 Section C.3.4 Preliminary List of Mine Activities

This section C.3.4 lists many "preliminary" activities during Construction, Operations, and Decommissioning and Closure. While many sound like generally good ideas, they can turn out to be bad ideas and not even possible at the Great Bear Project.

For example, here are some "preliminary" activities:

> "Overburden and organic material from the open pits will be either stockpiled or used for progression reclamation"
>
> "Mine rock extracted from the underground workings and open pits will be stockpiled, re-used as aggregate, or potentially re-used a consolidated rockfill underground"

The Project Definition Document of December 2022 assumed all the mine rock would have strong ML-ARD potential and would substantially contaminate water. Overburden was not even assessed although required by Ontario Regulation 240/00. It is understandable that the initial worst-case scenario may be modified as years go by and as ML-ARD studies are completed according to the 2009 federal ML-ARD Prediction Manual. However, there may be little change from the worst case at the Great Bear Project, but no one knows at this time. Thus, these "preliminary" activities can cause wider and worse impacts; no one knows at this time. Nevertheless, this perhaps-draft Detailed Project Description lists them anyway without pointing out their potential for adverse impacts.

This section also says,

> "As operations continue the open pit will have a progressively larger surface area and will become deeper"

The proposed pits are a concern to me as I do not see them justified by Kinross Gold. In fact, Figure C.5 shows that most of proposed pits and excavations are not needed to access most of the ore. Thus, there seems to be another, unstated reason for them, but I cannot see what it is.

10.3 Section C.3.5 Preliminary Decommission Approach

This section says:

> "Decommissioning and final closure of the Project site will be governed by the Ontario Mining Act, and its associated Regulations and Codes, and will be informed by ongoing engagement with Indigenous Nations and potentially affected stakeholders. The Act requires

> that a Closure Plan be filed for mining project before construction, and that financial assurance be provided so sufficient funds are in place to carry out the decommissioning activities.
>
> "A preliminary description of the proposed decommissioning and reclamation measures is provided in the text that follows. The preliminary measures are subject to consultation, additional engineering and regulatory review. The active phase of decommissioning and reclamation is expected to be completed within approximately three years of the end of operations. Environmental monitoring will continue after reclamation is completed, until such time as the closure objectives as determined in the Closure Plan have been achieved."

It is important to note that this preliminary closure plan, which should include early and unexpected closure but does not, will determine the initial financial security. Thus, all potential major sources of contamination should be identified and costed now, but this is far from the case.

Many serious long-term concerns are omitted and thus cannot be added at this time to the cost of the initial financial assurance. For example, the section on the Underground Mine does not mention the costly and serious water-quality degradation that would likely accompany the backfilling of "PAG" rock into the mine, where the rising, flooding water can become seriously contaminated beyond that seen at the surface. This seriously contaminated flooding water would likely eventually reach an equilibrium level where it would begin flowing out into the surrounding groundwater system and the environment years after closure. This would require long-term or perpetual pumping and treatment of groundwater, which could substantially or enormously raise the financial assurance.

Alternatively, the "PAG" rock (and overburden) could be kept in a stockpile at the surface where its ongoing seepage of infiltrating water through some type of cover would require perpetual collection and treatment. This section implies the ML-ARD would stop by incorrectly saying:

> "Reclamation measures will be designed to mitigate acid mine drainage / metal leaching concerns as needed. This may include design and placement of an appropriate cover over the mineral waste."

ML-ARD is not mitigated cheaply and permeable covers do not stop infiltration but may reduce it if well maintained in perpetuity, still leading to perpetual maintenance and water treatment. Very expensive impermeable covers may virtually encapsulate and isolate the contaminating rock and overburden if carefully maintained in perpetuity, which also includes additional costs for perpetual maintenance and repair.

Or perhaps as Section C.6 on Potential Alternatives states, the mine rock would be used as "reclamation material" where it could contaminate more of the site. Or the mine rock would be placed into "storage in depleted open pit". In the pits, the backfilled mine rock would contaminate inflowing water that would eventually fill and flow into the surrounding environment, or eventually drain down into the underground workings where the second paragraph above explains the fate of the underground water.

One way or the other, the closure cost only for the rock and overburden alone will likely be much higher than envisioned in this perhaps-draft Detailed Project Description.

There are other examples like this that are not recognized and costed in this Section C.3.5.

Therefore, whatever the current estimated cost of financial assurance based on Section C.3.5, it should be raised substantially higher. This would also cover the expense should early or unexpected closure occurs, which is credible and often expected but is not mentioned or considered in this Great Bear document.

10.4 Section F Potential Effects of The Project

Section F on potential effects of the project during Construction, Operations, and Closure starts with Table F.1 Preliminary List of Change to the Environment under Federal Jurisdiction.

The row of Table F.1 for the Fisheries Act during the Construction Phase says:

> "Alteration, disruption and destruction of fish and benthic fauna habitat from direct disturbance (including potentially from overprinting by mine rock and tailings management facilities), blasting and mine dewatering" with the Preliminary Area of Influence only "Project footprint"

For mine dewatering, the ongoing drawdown of groundwater and ongoing dewatering of surface waterbodies does not stop immediately as the pumps are turned off at the end of Operations, but can continue for many years afterwards through Closure. Also, the Area of Influence could be much greater than the Project Footprint (see Section 9.2 of this MDAG review). However, Operations and Closure does not mention this long-term ongoing impact. This illustrates how "Preliminary Changes" are only partially recognized in this Detailed Project Description, and important ones are not mentioned and considered.

Additionally, for Closure under the Fisheries Act Table F.1 says:

> "Potential for creation of fish habitat in new pit lakes, expected to be re-connected to the Dixie Creek system"

This shows a lack of understanding of water-quality impacts and ML-ARD, similar to the Great Bear "nonreactive mine rock and overburden" that does not exist (see Section 10.1 of this review). It sounds good to non-technical readers to say the pit lakes will be fish habitat and "re-connected" to Dixie Creek although they are not currently connected. On the other hand, technical readers know this is highly unlikely considering the type of rock and ML-ARD likely to come from Great Bear rock, pit walls, and underground mine walls. These Great Bear pits as proposed, long after Closure, should not be expected to meet the requirements of the Fisheries Act.

Table F.2 Preliminary Summary of Potential Environmental Effects says:

> "- Underground mine and open pit dewatering will affect the local groundwater levels and may affect surface water flows
> - Groundwater quality is not expected to be affected"
>
> "Preliminary Areal Extent:
> - Dewatering may result in a depression in the local groundwater level which is currently under investigation"

Section 9.2 of this MDAG review explains how Kinross Gold's groundwater modelling is aware of, but avoids showing, the substantial lowering of groundwater levels by dewatering to a remarkable depth of ~600 m in the rock, while the overlying overburden is virtually fully dewatered to its base. This dramatic lowering will be much more than the comfortable sounding word of "local" in the above quotations. It will be much worse than "local". This will also likely have a major impact on groundwater quality, as Section 9 of this MDAG review explains, despite Kinross Gold's unjustified and unreasonable expectation that "Groundwater quality is not expected to be affected".

Furthermore, surface creeks and lakes could be dewatered much more than modelled because modelled groundwater levels are simulated around 9 m higher than measured, reducing the modelled and predicted dewatering below reality. Baseline flows to local surface waterbodies, which are critical to the benthic ecosystem and aquatic life due to their differing chemistry and temperature, will be reduced by 34% and more, but no one yet knows how much more.

Section F.6.1 on Atmospheric Emissions has a major omission that shows the environmental impact from atmospheric emissions would be much greater than stated. Section 8 of this MDAG review has explained that fugitive dust at Great Bear, and any water used to suppress this dust, would have a substantially larger environmental impact than currently recognized and modelled. Thus, impacts from air emissions have been underestimated in this Detailed Project Description that could be used to determine an impact assessment.

Section F.6.2 Liquid Discharges states:

> "Mine water will contain suspended solids from mining and earthmoving activities, ammonia residuals from ammonia-based explosives, and residual hydrocarbons from heavy equipment operation. Leaching of the exposed bedrock within the underground mine and open pit may potentially contribute minor quantities of metals to the mine water."

This is another example of bad science appearing as technical information in this perhaps-draft Detailed Project Description.

- First, underground mine water will also contain dissolved metals and other inorganic contaminants.
- Second, since ammonia is expected to be so high from underground explosives that a special treatment circuit is needed for it, then the always accompanying high nitrate and nitrite that will not be treated but discharged to the environment will also be high and contaminating.
- Third, since underground mine water will contain hydrocarbons, why is there no option to treat these potential organic contaminants?
- Fourth, leaching of mine walls in underground workings and open pits can, and elsewhere have, seriously contaminated the mine water, with the contamination increasing as the area of mine walls increases during mining. This could happen at Great Bear because more than 10 km of underground workings would likely be mined. However, the ML-ARD testwork to predict this under the federal ML-ARD Prediction Manual will be in progress for at least a few years. So, once again this Detailed Project Description misleads by already concluding that the leaching "may potentially contribute minor quantities of metals to the mine water". The reality could just as easily turn out to be "the leaching will contribute substantially high and toxic quantities of metals to the mine water". No one knows yet, not even Kinross Gold and its consultant, WSP.

Some day in a future year, reliable "Modelling will be completed to assess the volume and quality of the water requiring management, which will be used in the design of the integrated water management and treatment facilities on site." At this time, the groundwater requiring management has clearly already been underestimated (see Section 9.2 of this MDAG review). Until then, no one knows with reasonable confidence how much water has to be treated, how severely it will be contaminated, and how thoroughly it will be treated.

The subsection on Process Plant says:

> "Excess process plant water is expected to be pumped with the tailings to a tailings management facility for storage. The tailings and process plant water will contain metals from the processing of metal-containing ore and residual processing reagent products. A cyanide destruction circuit will be established within the process plant to treat residual cyanide concentrations in the tailings and process plant water, prior to pumping to the tailings management facility."

A major aspect of water management and tailings management is the percentage of discharged process water that will be recirculated back to the process to minimize freshwater usage and contamination by "metal from the processing". This issue is not mentioned and thus is a serious omission. Additionally, "cyanide destruction" is not perfect and may not literally destroy cyanide but temporarily mask it until its release to the environment. These important issues are not mentioned either. Thus, this quotation gives the false impression that cyanide and metals will only be "residual" and will be treated to minimize them, but this is simply guessing that is not consistent with ML-ARD testwork so far.

Section F.6.4 on the Environmental Management System does not explain the currently likely scenario that one or more additional contaminants not currently recognized will arise in on-site water (see also Section 11 of this MDAG review). This would require at least months of storage of contaminated water on site until the treatment plant is expanded and updated. Therefore, the on-site storage of months of site-contaminated surface water and groundwater should be a major objective of the Environmental Management System.

10.5 Summary

In summary of this perhaps-draft Detailed Project Description of November 2023, the first cover page by Kinross says this document is "draft", but the second cover page by the authors, WSP, does not say "draft" so perhaps this is the final document. If so, it has not been signed by qualified professionals and thus should be rejected.

In any case, there are so many problems, misleading statements, errors and omission concerning ML-ARD, water quality, and environmental impacts that they cannot all be summarized well here. These problems include the following.

- The false statement that there will be no sources of mercury from the ore processing when in fact the tailings and concentrate from the process will contain mercury. The processing could even cause mercury and other elements to leach more quickly and become more mobile.

- Contrary to the impression given by this Detailed Project Description, cyanide destruction is not perfect and can simply mask the cyanide temporarily in the environment, but the important testwork to determine this has not yet been done for the Great Bear Project.

- Significant impacts on water quality can arise from seemingly benign proposed activities like paste backfill of tailings into the underground mine and dewatered filter-cake tailings, but the potentials for serious impacts are not recognized or not even mentioned in this perhaps-draft Great Bear document.

- Storm events and equipment upsets can lead to relatively large variations and unexpected impacts, day-to-day or even hour-to-hour, during proposed exploration and proposed mining. Instead, these Great Bear documents use averages like monthly which incorrectly assume flows will be the same every day of a month which is far from reality. Environmental impacts and spills can be caused by large variations, as well as longer-term averages, so the environmental risks of proposed exploration and proposed mining at Great Bear remain mostly unknown and not identified.

- Nonsense pseudo-scientific statements are used, like the aggregate required to build the Great Bear Project would be "nonreactive mine rock and overburden" which does not exist. This clearly shows that experienced and qualified professionals were not included in the writing of this perhaps-draft Detailed Project Description. If there is a true commitment to "nonreactive mine rock and overburden" which does not exist, then the Great Bear Project stops now.

- There is a lack of ML-ARD assessments for some site components like aggregate.

- There is a prevalent but likely false belief that "NPAG"rock will have little to no impacts on ML-ARD, water quality, and the environment. However, this has not been proven for the Great Bear Project and is likely wrong based on other minesites around Canada. "NPAG" rock can actually generate more acid than "PAG" rock and still release seriously contaminated levels of many metals and other elements at near-neutral pH.

- The financial assurance to ensure proper and fully paid closure of the proposed Great Bear Project is grossly underestimated based on existing information. Furthermore, the financial assurance should also include contingency costs for early or premature closure but it does not.

- There are likely devastating, expensive, and unrecognized ML-ARD consequences on water quality from the proposed relocation of "PAG" rock into the underground workings after operation.

- The ongoing, unproven, and likely wrong, belief continues that overburden would be environmentally benign, can be used across the site for reclamation, and can be sprayed with water to control dusting when it could instead create contaminating water around, below, and beyond the Great Bear site.

- There are unfounded beliefs that dewatering during exploration and mining would have minimal

effect on the local and regional water balance, and would not significantly dewater surface creeks and lakes including their environmentally important baseflow. These false beliefs are based on flawed groundwater modelling for the Great Bear Project explained earlier in this MDAG review.

- There is a false belief that dust blown off the site during proposed exploration and proposed mining and into the surrounding environment, vegetation, soil, water, and aquatic ecosystems is benign at "background" levels.

- A false belief is stated that only elevated and toxic ammonia, and no other contaminating nitrogen species from explosives that consistently accompany the ammonia, will appear in mine water during proposed exploration and proposed mining.

- There is an unsupported and likely substantially underestimated statement that the mine walls in the pits and underground workings "may potentially contribute minor quantities of metals to the mine water" instead of the more typical significant quantities of metals seen at many other minesites around Canada. This is taken to the likely ludicrous statement that there would be "Potential for creation of fish habitat in new pit lakes, expected to be re-connected [sic] to the Dixie Creek system".

- There is no recognition of the implications, costs, and impacts of storing months of contaminated mine water on the site should one or more "unexpected" yet currently predictable inorganic contaminants and ML-ARD occur on the site water during and after proposed exploration or proposed mining.

11. Water Treatment during Proposed Exploration and Proposed Mining

Most of the contaminated water at the Great Bear Project during proposed exploration and proposed mining would be subjected to water treatment. There would remain some fugitive contaminated water and contaminated dust that would impact the surrounding environment. This fugitive contamination has not been assessed in detail by Kinross Gold, and is even ignored or not recognized in several Great Bear documents as shown above in this MDAG review.

If fugitive contamination turns out to be minimal, then water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts. Therefore, proposed water treatment should be examined and justified in great detail. This has not yet happened for the Great Bear Project.

At this time, I could not find any detailed and professionally certified report on water treatment for proposed exploration and proposed mining. The previous sections of this MDAG review have discussed water treatment as it appeared in some documents, where the current information was found lacking or misleading.

Minewater-treatment plants are not off-the-shelf available at stores like Canadian Tire. This is because their treated effluent concentrations to the environment are very sensitive to the site-specific inflow rate of water and to the inflowing variations in aqueous concentrations of each contaminant element requiring treatment.

These treatment plants can be unstable when exposed to variable flows or to variable inflowing contaminant concentrations, resulting in only partially treated and still-contaminated effluents. Therefore, water treatment for proposed exploration and then again for proposed mining at the Great Bear Project has to be carefully designed, based on well-justified and professionally certified information on surface hydrology, subsurface hydrogeology, ML-ARD, and on-site geochemical source terms.

As shown in the previous sections of this MDAG review, this "input" information into the site-specific and reliable design of water treatment at Great Bear does not exist and will not likely exist for at least a few years. Until then, the available preliminary information is corrupted by errors and missing details. Therefore, it is not possible at this time to reliably define and design the required water treatment at Great Bear, or to estimate effluent concentrations, environmental impacts, and cumulative effects.

To provide some guidance to Grassy Narrows First Nation on aspects of water treatment at the Great Bear Project, it is helpful to review and comment on one of the latest documents that contain some details on possible water treatment. This document is: Great Bear Project Proposed Underground and Open Pit Gold Mine, a PowerPoint presentation made to Asubpeeschoseewagong Netum Anishinabek, dated November 10, 2023

Slide 20 of this presentation is entitled "Water Treatment". It points out that:

> "Contact water discharged to the Chukuni River will be managed to achieve regulatory requirements."

It is important for Grassy Narrows First Nation to recognize that "regulatory requirements" can vary vastly and that the applicable and protective requirements have to be carefully chosen based on site-specific information like flow rates and variations in influent (ML-ARD) and effluent concentrations. Alarmingly, Table 5-6 shown on Slide 20 invokes the "MDMER" or Metal and Diamond Mine Effluent Regulations, which allow toxic levels of metals and other elements. For example, normally toxic levels of 100 ug/L and more are allowed for arsenic and copper, and normally toxic 80 ug/L and more are allowed for lead.

This should be an immediate warning to Grassy Narrows First Nation that Kinross Gold does not intend to treat the site water to safe levels. Instead, treatment will only reduce concentrations to still-toxic levels and then rely on dilution in the Chukuni River to eventually reduce it almost to background levels.

The usage of toxicity dilution in the Chukuni River would create a "mixing zone" for some distance in the river, in which toxicity still exists and for which Fisheries and Oceans Canada would have to authorize the mixing zone. There appears to be some hydrodynamic modelling already done for this mixing zone in the River, but no details like flow rates and their variabilities were provided. Because the previous sections of this MDAG review showed that long-term to perpetual treatment and dilution may be needed for the Great Bear Project, Grassy Narrows First Nation should understand this will represent a very-long-term impact.

Additionally, such long-term ongoing discharge and dilution will add to cumulative effects, about which Grassy Narrows First Nation has expressed serious concerns.

Slides 20 and 21 present additional details on treatment. For example, a special and likely expensive ammonia treatment circuit will be included to treat elevated and toxic ammonia from blasting residues. Remarkably, nitrate and nitrite, which can also be toxic and can stimulate eutrophication in the Chukuni River and Dixie Creek, always accompany ammonia from the blasting residues. However, they are not even recognized here or in other Great Bear documents. This is a serious and unacceptable omission for the Great Bear Project.

Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

Slide 20 also commits to "ultrafiltration" which typically removes all suspended particles coarser than about 0.02 um. Because "dissolved" concentrations include nanoparticles and small particles up to about 0.45 um, this proposed ultrafiltration would also lower the functionally "dissolved" concentrations, but not those of fully dissolved elements. Thus, Great Bear treatment should be capable of approaching CCME (Canadian Council of Ministers of the Environment) safe criteria for aquatic life, but may not meet Grassy Narrows First Nation water-quality criteria (GNFNWQC). CCME aquatic-life guidelines and GNFNWQC could replace the toxic MDMER criteria and significantly reduce or eliminate the mixing zone and cumulative effects in the Chukuni River.

However, none of these details are discussed or mentioned in Great Bear documents.

Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge". In many jurisdictions, treatment sludge like that proposed for the Great Bear Project can reach "hazardous" or "special" waste levels, requiring the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and in sediments including soils and benthic ecosystems.

All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge. This is a major risk for serious environmental impacts that should be addressed in great detail for proposed exploration and proposed mining. I recommend that Grassy Narrows First Nation require intensive studies on the treatment sludge that will remain and be managed somewhere in perpetuity.

In summary for water treatment, Great Bear documents invoke water treatment as the major process that would prevent or minimize environmental impacts of proposed exploration and proposed mining. This is not literally true, because there will be fugitive contaminated water and contaminated dust leaving the site, but this fugitive contamination is ignored or not recognized in many reviewed Great Bear documents.

In any case, water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts, and thus requires intensive study and characterization. However, at this time, water treatment for proposed exploration and proposed mining is ambiguous and contradictory among the documents. This should be expected because the input flows and input contaminant concentrations (ML-ARD) will not be known reliably for at least a few years. Nevertheless, there are serious concerns about water treatment now including the following.

- Kinross Gold does not expect to treat site water to non-toxic levels. Instead, treatment would only be down to still-toxic levels based on the Metal and Diamond Mine Effluent Regulations. Thus, Kinross Gold intends to rely on significant dilution of its contaminated effluent within a "mixing zone" in the Chukuni River. Such a mixing zone would include zones of significant toxicity and would require formal authorization from Fisheries and Oceans Canada. In any case, this discharge of effluent would add to cumulative effects, which is a particular concern of Grassy Narrows First Nation.

- Expensive and intensive treatment for ammonia, derived from blasting residues, is proposed. However, toxic levels of nitrate and nitrite, that always accompany the ammonia and which can cause eutrophication and other impacts in the Chukuni River and Dixie Creek, are completely ignored.

- Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

- Ultrafiltration may substantially reduce effluent concentrations for those elements not fully

dissolved, mixing-zone size, and cumulative effects. However, there are no details on this ultrafiltration in the reviewed Great Bear documents.

- Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge", which can reach "hazardous" and "special" waste levels in some jurisdictions. Thus, treatment sludge requires the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and sediments including soils and benthic ecosystems. All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge that will remain and be managed somewhere in perpetuity.

Boozhoo MINES, IAAC, Kinross and Great Bear Resources:

RE: The Great Bear Gold Mine Project

On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows First Nation"), we write to share with you Grassy Narrows' preliminary position with respect to your activities in relation to the Great Bear Gold Project.

The Project will have an adverse impact and requires an impact assessment

Grassy Narrows is deeply concerned by the Great Bear Gold Project being pursued by Kinross and Great Bear Resources with support from the Ministry of MINES as well as the process recently begun by the Impact Assessment Agency of Canada (IAAC).

Decades of industrial activity, authorized and encouraged by Ontario and contrary to Grassy Narrows' will, have led to well-documented and extensive harm to our Territory, our way of life, our rights, and our health. As a result, our people suffer intensely from impacts including premature death, disease, poverty, and suicide.

The Great Bear Gold Project falls within the area that Grassy Narrows people have historically and currently use for the exercise of our rights and way of life. It is also upstream from our community. Pollutants in the water and impacts on the surrounding land, fish and wildlife will have a direct impact upon us and could also exacerbate mercury contamination in our waterways.

ANA has repeatedly and clearly communicated with the Crown and the mining industry that our people are in crisis, the environment which supports us is severely impacted, our health is failing. The cumulative impacts continue to significantly interfere with our treaty, Aboriginal and inherent rights.

The Great Bear Gold Project will have an impact upon areas that Canada claims as within federal jurisdiction, such as species at risk, fisheries, waterways and Indigenous peoples. Grassy Narrows asserts that the IAAC must conduct an impact assessment in the circumstances.

The Crown's outstanding obligations to Grassy Narrows should be resolved in a nation-to-nation process.

For many years, ANA has written to Ontario to invite the Crown to a government-to- government table to address fundamental issues between us, including the Crown's unmet obligations to us about our rights, our land, our self-determination, and the impacts of industry and government policy on our land and people. These issues have been unresolved between our governments for many decades. Reaching agreement in good faith through a government-to-government table is the way to resolve these important issues and to put in place effective measures to protect us from further harm.

Ontario and Canada have yet to accept this invitation. Most recently, by letter dated November 27, 2023, Ontario explicitly refused to participate in a table to discuss "jurisdictional issues" raised and rejected nearly all of the issues proposed by ANA including most of those related to mining.

Instead, Ontario has explicitly recommended that mining companies explore on and around our Territory, has unilaterally granted roughly 6,000 mining claims on our Indigenous Protected and Conserved Area, and allowed companies to pursue increasingly advanced work towards mines that pose a serious threat to Grassy Narrows. This activity has occurred without our consent, without meaningful consultation and accommodation, and usually without even prior notice under the antiquated "free entry" mining regime.

Grassy Narrows' concerns about the process

Until recently, the Crown and the companies associated with the Great Bear Gold Project have shown little willingness to meet with us, nor respond substantively to many of our communications. Indeed, we have only recently learned that the Crown and companies provided notice to other Indigenous Nations of permit applications concerning the Great Bear Gold Project

as early as 2017 and have signed Advanced Exploration Agreements with Wabauskang and Lac Seul First Nations. In contrast, Ontario approved a number of permits without notice of any kind to Grassy Narrows.

Now that gold has been found, the Crown and Kinross are suddenly interested in giving the appearance of consulting with us, but only to the extent that it furthers the already advanced plans, made without Grassy Narrows' involvement, to develop an industrial gold mine in our headwaters.

Even if Ontario had complied with its own laws, Ontario's "free entry" mining exploration and mine development process is not the correct way to make key decisions between our two governments. This process is deeply unfair and biased in the favour of multi-billion-dollar mining companies. It ignores our laws, our vision for our land and people, and our processes for making decisions affecting our territories.

Our ongoing and urgent crisis leaves us unable to meaningfully engage about mining. To make matters worse, we receive no support from Ontario to inform ourselves, gain technical and legal advice, and to engage in a fair way about mining. The IAAC has offered a mere $5,000 in capacity funding to respond to a 100-page technical Initial Project Description and the funding was made available only after the submission deadline for comments has passed.

The path to reconciliation

We are on a healing journey to recover from the extreme damage that colonization, and attempted forced assimilation have done to our people, including through the imposition of Crown policy and regulatory schemes related to residential schools, dams, relocation, mercury contamination, child apprehension, industrial logging, and mining. We need to allow the land to heal because healthy land will help to heal our people. This is what reconciliation means to Grassy Narrows. Let us protect our land and water so that we can heal our people.

The boom in mining exploration in our area is causing great anxiety and fear among our people. It is setting back our healing. If the Crown decides to allow mining, and the risk of further pollution and other impacts, there will be more heartache, sickness and loss for our people. This mining activity will only lead to more grassroots resistance, litigation, and public controversy over conflict minerals. It will take the relationship between the Crown and Grassy Narrows further away from the path of healing and reconciliation.

Grassy Narrows says 'no' to the Great Bear mine and related activities.

We strongly urge the Crown and your companies to reconsider your unilateral and bullying approach to pushing mining activity on our First Nation. We urge you to seize this opportunity to set a course for a future that is free of conflict over mining in Ontario.

We call on the Crown and your companies to respect the healing path for Grassy Narrows and not to further impair the exercise of our constitutionally protected Aboriginal and treaty rights, our inherent Indigenous rights, our health, and wellbeing.

Grassy Narrows provides preliminary comment on the project under duress

We know that Ontario and Canada will move ahead with approvals for damaging mining activity if we do not speak up. For that reason, we are writing to you under duress to express our preliminary concerns about this project before it advances any further. These serious concerns with both how the project has been pursued and the impacts on our rights and interests, are set out in the attached document. These submissions are by necessity preliminary in the absence of capacity and support to conduct our own studies and obtain expert technical advice.

Please ensure that you copy our Land Protection Team on all communications on this and related matters.

VII. Gold does not justify the impact to Grassy Narrows 51
VIII. A Choice, an Opportunity 52

I. The Context

Who is Grassy Narrows

Asubpeeschoseewagong Anishinabek (Grassy Narrows First Nation) is an Anishinaabe First Nation with traditional territory in what is called northwestern Ontario. Grassy Narrows people exercise inherent Indigenous rights, and Aboriginal and Treaty rights. We have cared for and lived on our lands for countless generations. Grassy Narrows people hunt, trap, fish and practice our Anishinaabe way of life to provide for ourselves, our families and community.

We exercise our inherent right to self-determination and law-making powers. Our inherent rights are given to us by the Creator. In addition to our inherent rights, Grassy Narrows people exercise Aboriginal rights and established Treaty 3 rights which are protected by section 35 of the *Constitution Act, 1982*.

In 1873, the Anishinaabe adhered to Treaty 3. The Treaty 3 Commissioner promised the Anishinaabe that the Treaty promises would protect our harvesting practices forever, which would allow our people to hunt, fish, trap, gather, and harvest throughout the Territory as they had before "as long as the sun shone and the waters flowed." This promise was more than a continuation of our pre-existing harvesting rights. The Anishinaabe did not agree to the erosion of our harvesting rights.[1]

Our territory is located in the Boreal Shield ecoregion in a mixed forest transition zone from the Great Lakes St Lawrence Forest to the Boreal Forest. The Whiskey Jack Forest is the English name of the forest that covers a large portion of the Territory; the English-Wabigoon River System is a central waterway in the Territory. The land and waterways of the Territory sustain Grassy Narrows peoples' way of life.

Grassy Narrows' Territory is the foundation of who Grassy Narrows people are as Anishinaabe people. We follow the teachings of the Elders to be responsible for the Territory and to *Manaachitootaa Aki* (protect the land).

Social and Cultural Impacts of Crown Law and Policy.

Despite these sacred promises, for many generations the Crown has imposed harmful law and policy on us, including through the *Indian Act*, the banning of our ceremonies, regulation of our hunting and trapping, residential schools, regulation of the wild rice, relocation, the 60s scoop, the underfunding of our schools, inadequate health care, and the ongoing removal of our children from the community.

These policies have caused grave harm to our people and impaired the exercise of our rights. They have undermined our strong society and way of life and have left us more

vulnerable to the impacts of industry.

The Cumulative Effects of the Mercury Crisis and Industrial Activities Impacts.

Starting in at least 1962, a chlor-alkali plant in Dryden, Ontario, began discharging mercury into the English-Wabigoon River system. Approximately 9,000 kilograms of mercury were discharged into the river system that flows through our Territory and is a lifeline for Grassy Narrows people. Our live-giving river became a source of invisible poison.

The impacts of the mercury contamination have been devastating to the people of Grassy Narrows and our Territory. The presence of mercury led to the methylmercury contamination of the fish and Grassy Narrows people. The local commercial fishery shut down; Grassy Narrows' economy collapsed; Grassy Narrows people descended into poverty; Grassy Narrows people suffered, as they continue to do, from debilitating health symptoms and premature death; and our Anishinaabe way of life was gravely threatened and changed when we could no longer safely eat fish and exercise our fishing practices as we had before.

In the 1970s and 1980s, Grassy Narrows called on Ontario to respond to the mercury crisis by taking concrete action, including by agreeing that Grassy Narrows would control our Territory. As the river was poisoned, we wanted to have more control over our Territory and the natural resources in it to be able to protect and benefit from the part of our Territory that was still healthy – the land. Instead, Ontario authorized extensive clearcut logging in the Territory from roughly 1980 to 2008, which likely released new, or additional, sources of mercury into the watershed, and increased methyl mercury contamination of fish.

Multiple expert reports and publications have detailed the impacts of mercury contamination on the health of Grassy Narrows people, including the following, which are enclosed:

- 2015 Expert Report of Dr. Donna Mergler
- Grassy Narrows Community Health Assessment Summary Reports, 2018
- Philibert et. al. (2020), "Mercury exposure and premature mortality in the Grassy Narrows First Nation community: a retrospective longitudinal study", *The Lancet: Planetary Health* Vol. 4(4), E141-E148
- Philibert et. al. (2022), "Past mercury exposure and current symptoms of nervous system dysfunction in adults of a First Nation community (Canada)" *Environmental Health* 21:34.
- Mergler. D. et. al. (2023), "The Contribution across Three Generations of Mercury Exposure to Attempted Suicide among Children and Youth in Grassy Narrows First Nation, Canada: An Intergenerational Analysis" *Environmental Health Perspectives* 131(7).

These reports highlight the grave impacts of mercury on the health and wellbeing of

Grassy Narrows. They establish that Grassy Narrows people cannot withstand further impacts from the release of new mercury into Grassy Narrows' land, lakes, rivers, fish, and people, nor an increase in the net methylation of existing mercury. Our rights have already been highly compromised by the mercury crisis. Our nation cannot withstand further infringements of rights. No further impairment of our rights, our health, and our wellbeing can be justified.

Our fish in the Wabigoon River remain the most mercury contaminated in the province. Our people of all ages continue to suffer from mercury related diseases and loss of wellbeing. Our employment remains far below what it was in the 1960s following the collapse of our subsistence, sport, and commercial fishery due to mercury.

The mercury crisis is but one in a long series of industrial attacks which have been imposed on us against our will. These include the damming of our rivers, industrial logging, and mining activity. Each of these industrial attacks has had grave impacts on its own. In addition, each of these industrial attacks has compounded the existing harm that remains from previous attacks, creating unbearable cumulative impacts, thereby prolonging, and exacerbating our inter-generational crisis.

These extreme and compounding industrial impacts have been authorized and encouraged by the Crown without any serious consideration of their cumulative effects on Grassy Narrows and the exercise of Grassy Narrows' rights. We have raised clear concerns since at least the 1970s that our environment, rights, way of life, and our health, were at or beyond, the breaking point due to the impacts of industry on the resources on which we have heavily relied for our wellbeing, livelihood and the viability of our community. In the 1980s, and again in 2007, we declared moratoria on further industry on our Territory so that we could heal our people and rebuild our independence and wellness.

And yet, to this day, with respect to our Territory and vicinity, Ontario has failed to increase our control and use, failed to conduct a collaborative Landuse Plan; failed to complete a source water protection plan; failed to carry out a comprehensive environmental assessment; and failed to undertake an assessment of cumulative effects. The repeated failures of the Crown to act honourably to resolve the crisis have resulted in serious, compounding adverse impacts over time, including:

(1) Severe cumulative impacts on our territory and Treaty harvesting, hunting and fishing rights, making these rights impossible to exercise in a meaningful way;

(2) Severe adverse health effects and death, including, as found in recent scientific research, high rates of conditions impacting learning in children, disease, suicide attempts, and the premature death of our people; and

(3) Extreme poverty, food insecurity, loss of Anishinaabe way of life, and other poor socio-economic indicators of wellbeing which are ranked significantly worse than average Indigenous communities in Ontario and Canada.

(4) Collective impacts to our society and community.

Ontario ignored our pleas and our moratoria and continued to allow industrial activity, including the granting of mining claims on our Territory against our will, and advancement of mines all around us, without considering how mining activities add to, compound, exacerbate, and prolong previous harms. The cumulative impacts of industry have been devastating. The impacts include, but are not limited to:

- Our river that gives us life remains poisoned.
- Our walleye are unsafe to eat.
- Our sturgeon are rare.
- Our moose are scarce.
- Our caribou are nearly extirpated.
- Our pine marten habitat is depleted.
- Our forests are fragmented.
- Our medicines are tainted.
- Our sacred landscape is desecrated and scarred and traplines have been clear cut.
- Our way of life is diminished.
- Our people suffer from poverty, food insecurity, disease, premature death, and suicide.
- Our inherent, aboriginal, and treaty rights are impaired
- Our health has been harmed.
- We have been discriminated against.

II. Ongoing Breaches of Crown Obligations: The 1978 Memorandum of Understanding, Honour of the Crown, and Fiduciary Duty

Ontario and Canada (collectively, the "Crown") are our treaty partners. As elaborated below, through the treaty relationship and Crown actions over time, including entering into legal agreements following the start of the mercury crisis, the Crown assumed obligations and duties owing to Grassy Narrows. The Crown must uphold the treaty promises, uphold terms of its agreements, and act honourably in its dealings with Grassy Narrows.

Authorizing and permitting mining activities in our territory without our consent violates Ontario's and Canada's outstanding obligations and duties to Grassy Narrows and violates the Crown's duty to act honourably in all its dealings with Grassy Narrows.

1978 MOU and Dishonourable Conduct.

In 1978, Ontario and Canada signed a Memorandum of Understanding with Grassy Narrows in which the Crown committed to resolve in good faith the impacts of mercury on the environment that Grassy Narrows people rely upon for the viability of our community, and the related health, social, economic, cultural, and environmental impacts on the people of Grassy Narrows ("1978 MOU"). It was agreed that the issues would be resolved through a combination of financial compensation and land, and

furthermore in a manner that would enhance Grassy Narrows' self-determination, self-sufficiency, and control over local affairs wherever possible.

Some agreements were reached that partially implemented some of the 1978 commitments. For example, agreements were reach with Canada in 1984 and with Canada, Ontario and the mercury polluters in 1985.

However, the Crown has outstanding obligations owing under the 1978 MOU. These outstanding obligations include (but are not limited to) increasing Grassy Narrows' access to, protection of, and control over lands and natural resources in our Territory.

Moreover, the Crown has engaged in a course of dishonourable conduct before, during the negotiations, and since, and has consequently failed to meaningfully support Grassy Narrows' recovery from the mercury crisis.

The Crown's unmet fiduciary duties

The Crown and Grassy Narrows have a *sui generis* fiduciary relationship, and our treaty rights attract fiduciary obligations. In the time since the Crown and Grassy Narrows entered into a treaty relationship, the Crown seized functional management and control of our lands and water. The Crown assumed a duty to Grassy Narrows when exercising that control over our Indigenous interests including our pre-existing legal interests in exercising our fishing, hunting and trapping rights and other traditional practices such as medicine gathering and wild rice picking.

Grassy Narrows has been at the mercy of the exercise of Ontario's imposed fiduciary decision-making over our land as Ontario unilaterally authorized industrial activity, and otherwise has made decisions that affect the land, water and other natural resources of our area which we rely on to exercise our rights, practice our way of life, and maintain our health.

Under imposed Crown management and discretionary control, the health of our land and our people have seriously declined, our way of life has been degraded, and the exercise of our treaty rights has been impaired.

The Crown's abandonment of negotiations required by the 1978 MOU

From the outset of our discussions under the 1978 MOU, Grassy Narrows was clear that to recover from the impacts of mercury and other harms, we need Crown recognition of Grassy Narrows' ownership, control, and protection of a large part of Territory, which will allow Grassy Narrows to make decisions with respect to our land that support our way of life and our livelihood. In the 1970s, 1980s, and 1990s Ontario committed to negotiate increased Grassy Narrows control over our lands, in addition to providing meaningful compensation for our people.

In the 1980s, and since, we called for a moratorium on industrial activity in our Territory until our negotiations with Ontario were concluded. However, rather than honour this moratorium, the treaty promises, and the 1978 MOU obligations, Ontario unilaterally

abandoned the negotiations in the mid 1990s and exercised its imposed control in a way that further unleashed industry on our area to our detriment.

Ontario has repeatedly acted unilaterally to encumber and degrade our Territory against our will, including by granting industrial logging licenses and nearly 6,000 mining claims; industrially logging our forests; and constructing industrial access roads and bridges (e.g. The Separation Lake Road and bridge) to facilitate further resource extraction and environmental degradation. Canada has stood by and watched, allowing our lands, waters, rights, and way of life to be trampled.

The Crown's dishonourable conduct and abandonment of its fiduciary obligations continue. Ontario's Ministry of Mines has granted thousands of mining claims against our will, including granting mining exploration permits without any prior notice to us.

Ontario has failed to accurately identify the ANA Area of Interest on mining activities.

The Ontario Ministry of Mines has never meaningfully addressed the question of the extent of Grassy Narrows' area of interest with respect to mining.

In the 1980s, the Ontario Ministry of Natural Resources created its own map to identify a Grassy Narrows Traditional Land Use Area (the "1980s TLUA Map") for the purposes of mediated negotiations between Grassy Narrows and Ontario with respect to a section of the Territory required by Grassy Narrows to restore its economic self-sufficiency. The map used straight lines, which are not reflective of the boundaries of the full Territory and does not include the northern portion of the Territory.

Between 2008 and 2017 Grassy Narrows and Ontario engaged in discussions on forestry pursuant to the Grassy Narrows Ontario Process Agreement (the "Process Agreement"). As part of that process, Grassy Narrows submitted a map of the "Grassy Narrows area of interest for forestry", which included areas that are outside the 1980s TLUA Map boundaries.

When Grassy Narrows passed our Land Declaration in 2018, we shared a map of an area we have identified as the "Indigenous Protected and Conservation Area" (IPCA). The IPCA boundaries mirror part of the area of interest for forestry. The IPCA boundaries have always been provisional, as Grassy Narrows continues to engage in a process of reviewing the knowledge of our historical and current land use. In addition, the western notion of linear boundaries on maps conflicts with our Indigenous knowledge systems, which are based on relationships and complex webs of protection, use, kinship, sharing, travel and trade that do not begin and end at a line.

Shockingly, Ontario relied on the 1980s TLUA Map as the consultation area for mining, despite having knowledge that the map was not accurate.

Grassy Narrows is currently pursuing litigation challenging nine mining exploration permits (not related to the Great Bear Gold Project) that Ontario approved without

notice to Grassy Narrows.[2]

Among other relief, Grassy Narrows seeks the following remedies in the litigation:

> a declaration that Ontario cannot consider mining activities in the subject area of the Territory, including issuing exploration permits, until the parties negotiate and reach agreement on **timely enforceable mechanisms to assess and manage the cumulative impacts of mining, logging, hydro-electricity projects, other industrial development, mercury contamination, and governmental policies or programs that may infringe Grassy Narrows' treaty rights, and to ensure that these constitutional rights are respected**;

These mechanisms are not yet in place and the judicial review remains unresolved.

As further described below, Grassy Narrows has only very recently learned that the Ministry of MINES approved a number of permits for the Great Bear Gold mine with no notice to Grassy Narrows.

It is only in very recent times, and after much conflict, that Ontario has begun to ask Grassy Narrows about what our area of interest for mining is. After many years of advocacy by Grassy Narrows, Ontario's Minister responsible for mines finally responded on November 1, 2022 with a new map that Ontario proposed as the area for consultation on mining related activities.

Ontario's proposed consultation area on mining appeared to deliberately carve out the Great Bear Project Area. The information provided by Ontario to explain how they arrived at the proposed boundaries was cursory and insufficient for understanding how the boundaries were arrived at. Grassy Narrows informed the Ministry that their proposed map is not complete and requested capacity support to do the work necessary to respond. However, no support has been provided to date.

On November 2, 2023, Grassy Narrows provided two versions of a map setting out our Interim "Area of Interest" for mining. The maps differed in scale only. The map was provided with the following cautions:

- The maps are an interim product created under duress arising from the escalation of imposed mining activity by the Crown and industry and for the sole purpose of identifying an interim area for negotiations on mining related activity.

- The maps are not a complete representation of Grassy Narrows' area of interest. Due to the unique circumstances and capacity constraints, Grassy Narrows has not completed comprehensive studies required to fully determine its area of interest including, but not limited to, land use and occupancy, ethnohistory, archaeology, biology, and hydrology. For example, rights and interests

[2] Grassy Narrows First Nation v. Director of Exploration, Ministry of Northern Development, Mines, Natural Resources and Forestry, Ontario Divisional Court File No. 881/21.

associated with air quality, migratory birds, travel routes, marten, lake sturgeon, wolves, eastern cougar, landscape intactness, climate resilience, biodiversity, genetic diversity, and many other factors are not reflected in these maps.

- In addition, linear boundaries are an imposed non-Indigenous concept that do not accord with the nature of Grassy Narrows' relationship with the land which includes extensive interconnectedness, reciprocity, travel, sharing, and trade.

- These maps do not limit any claims by Grassy Narrows people to assert their rights and interests throughout their territory and to protect themselves from harm to their health, rights, way of life, livelihood, society, and environment. Grassy Narrows people have Treaty rights, and practice them, throughout the Treaty 3 area. Grassy Narrows people also have inalienable inherent rights given by the Creator, some of which are affirmed in international law and instruments. The Grassy Narrows people are the true experts about their land, rights, and interests.

<u>The Great Bear project area falls within the core area of Grassy Narrows' Interim Area of Interest for Mining map.</u>

Despite Grassy Narrows' efforts to further these negotiations, there is no agreed upon area for consultation on mining activities.

Sharing of information about our Homeland is a sensitive topic that requires deep trust. After so many decades of having our trust, our vulnerability, and our lands abused by Ontario, many of our knowledge holders do not consent to sharing sensitive lands information with Ontario. Trust must be rebuilt to meaningfully engage on this topic.

Grassy Narrows Laws Have Not Been Respected.

Neither the Crown nor the companies have formally acknowledged and respected Grassy Narrows' moratorium and Land Declaration. The Crown has not joined us to harmonize Crown law with Grassy Narrows law and to find a path forward towards reconciliation that provides space for Grassy Narrows' inherent Indigenous rights and constitutionally protected Aboriginal and treaty rights to be meaningfully realized and protected.

We have written many times to request that the Crown come to a senior negotiation table with Grassy Narrows to address the wrongs committed against our people, the effects of which continue to this day, and to prevent further damage. We call on Ontario to return to the mediation process first established in 1978 in response to the mercury disaster to finally reach an honourable agreement regarding the control and protection of our Territory and fair compensation for Grassy Narrows people.

Instead of coming to the table to honourably resolve outstanding issues and obligations, Ontario has unilaterally granted mining claims and permits and now is supporting the development of a gold mine in our headwaters.

III. The Crown Must Address Capacity Barriers

Grassy Narrows has repeatedly advised both the Crown and the Companies that it cannot meaningfully engage in negotiations while it faces significant and unique barriers.

1) Insufficient information: Upon learning of the Great Bear Gold project, Grassy Narrows immediately requested additional information about the project and the extent to which our Laws had been taken into account and its adverse impacts considered. This information is essential for us to understand and respond to any efforts at engagement. After a lengthy delay, the Ministry recently provided responses that can only be characterized as preliminary and partial.

2) Capacity funding: The process of evaluating proposed mining activities and engaging with MINES, the IAAC, and mining companies comes at an expense to ANA. We must hire staff, engage our community, carry out our governance process, and obtain professional support from experts, lawyers, and advisors to engage in a meaningful way.

Grassy Narrows is even more impoverished than our First Nation peers due to the ongoing impacts of mercury poisoning. We lack the funds required to engage in an informed and fair way.

During the summer of 2023, MINES staff indicated that, after many years of requests, MINES will fund some ANA capacity needs. We provided MINES with a document summarizing the kinds of capacity supports that we would need in order to meaningfully engage on mining, including compensation for staff and to hire experts. After many months of awaiting an update, on November 27, 2023 MINES clarified that its promises of capacity supports amount only to funding in an unspecified amount for a “Mineral Development Advisor”, a position that Grassy Narrows has never requested funding for.

No funding is currently in place. MINES must come to the table on our issues and commit to funding ANA’s reasonable costs of engaging in an informed and fair way.

While IAAC offered $5,000 in capacity funding to ANA, this funding was offered after the deadline for submissions on the List of Issues. The amount offered is insufficient to meaningfully review lengthy technical documents that engage many areas of expertise, to engage with our people, to carry out our governance process, and to prepare a response. This is the same on-size-fits-all funding offered to other First Nations, NGOs, and other ‘stakeholders’. It does not consider our unique circumstances nor our position as an Indigenous nation.

3) Pandemic Considerations: COVID-19 infection rates, as well as other respiratory illnesses in this region of Ontario are high again. Our people are especially vulnerable to disease because of our high pre-existing rates of co-morbidity, crowded and inadequate housing, inadequate nutrition due to food insecurity, and the immune impacts of mercury. The health of our people is our priority. We are informing you that, in addition to our other concerns, mining exploration proposals are unwelcome during outbreaks

and other public health emergencies.

4) Mercury Crisis and Industrial Impacts: Our territory has already experienced a great deal of harm from industrial activities including mercury, damming, industrial logging, and mining. The cumulative effects of these industrial impacts have already passed the point of an unreasonable, unjustifiable impact on the exercise of our Treaty rights, and on our health and wellbeing. As a result, our community suffers from unusually high rates of conditions including poverty, food insecurity, disease, neurological conditions, conditions affecting learning, premature death, and child and youth suicide. The social conditions created by mercury poisoning and the cumulative impacts of industry place us in an ongoing extreme crisis. As a result, we are unable to meaningfully engage on mining exploration in the absence of the necessary supports to resolve and recover from the ongoing mercury crisis.

5) Fundamental outstanding issues must be addressed before meaningful engagement can occur: As described above, many fundamental issues remain unresolved between Grassy Narrows and the Crown including unmet obligations, broken promises, conflicting laws, cumulative impacts, violated trust, justice owed, and outstanding reconciliation. These are upstream strategic issues to which individual mining projects are subsidiary. We cannot address one mining project meaningfully, when the fundamental questions are not addressed. These questions include:

- How will the Crown respect Grassy Narrows' inherent rights and rights recognized under international law and related instruments?
- How can the Treaty relationship between the Crown and Grassy Narrows be respected and restored?
- How can the written text of the Treaty be reconciled with the oral and written histories, and Ontario Superior Court findings, that the taking up clause and the cede and surrender clause were never discussed nor agreed to?
- Who has decision making authority over lands and resources in our area?
- How can Grassy Narrows law and Crown law be harmonized with respect to the land?
- What lands should be open to mining and what lands should be protected?
- How will the Crown's unmet obligations arising from the Treaty, the 1978 MOU, and other sources be fulfilled?
- How will Grassy Narrows' ownership, control, and use of our lands be increased as promised?
- How can the damage already done to our land and our water be restored?
- How can the harm to our sacred landscape, our spirituality, and our relations be repaired?
- How can we assess and prevent the cumulative impacts of industrial activity from further harming us?
- How can the collective damage to our society, our community, and our families be reversed?
- How can our health, our wellness and our way of life be returned to its former status?

- How can our self-determination, our independence, and our self-sufficiency be rebuilt?
- Is it possible to reconcile while the harm continues, while we bury our youth?

For many years we have been seeking to resolve important issues with the Crown that relate to mining. A summary list of some of these issues can be found at **APPENDIX A**.

The Crown apparently has little interest in these questions and little willingness to address them with us, to act honourably, nor even to come to the table with us about them. When we meet with senior officials from MINES and MNRF, they tell us that they have no mandate to discuss these issues, but they will bring them to the Minister.

After years of seeking a meeting with the Minister our then Chief and Council finally met with then MNDMNRF Minister Rickford in Toronto on November 18, 2021. At the long-awaited meeting Minister Rickford refused to discuss our mining concerns but promised to come to Grassy Narrows soon to discuss mining at an open forum in our community. Neither Minister Rickford nor his successors have honoured this promise.

In a largely analogous situation where Grassy Narrows and the Crown had a conflict over a different form or resource extraction, the 2004-2009 Whiskey Jack Independent Forest Audit found that:

> There are fundamental differences in the viewpoints between GNFN and MNR regarding forest management principles and practices. It is the audit team's opinion that these differences cannot be resolved without the Province setting aside many of the requirements to manage the Whiskey Jack Forest under the CFSA and the FMPM, and relinquishing significant authority to the First Nation to manage portions of the Whiskey Jack Forest according to the desires of the GNFN community. The audit team further believes that the forest management planning process did not anticipate, nor was it designed to resolve the type of dispute currently being experienced on the Whiskey Jack Forest.

Similarly, the *Mining Act* and its regulations and the IAAC regulations did not anticipate, nor were they designed to resolve the serious grievances, outstanding obligations, and the type of dispute currently being experienced over mining around Grassy Narrows. Resolving this dispute will require sincere, honourable, government-to-government engagement on the fundamental issues that have brought us to this point. Only once that occurs, can we meaningfully engage about specific permits and projects without repeating and exacerbating the legacy of past and ongoing harms.

IV. The Great Bear Gold Project: The Crown's failure to inform, meaningfully consult, and gain our consent for project activities.

The Great Bear Gold Project falls within Grassy Narrows' Interim Area of Interest for Mining

We have enclosed a copy of Grassy Narrows' map of our Interim Area of Interest for Mining, which is described above.

The limited preliminary research that we have been able to conduct confirms that the Great Bear Gold Project is within the area where Grassy Narrows people have historically, and continue to, practice our way of life and our Treaty rights.

There is strong ethno-historical evidence that Grassy Narrows has a longstanding connection to this area dating back to the time of the Treaty and before. This includes historical reports, fur trade records, ethnological work, and other records. Grassy Narrows First Nation historically hunted, fished, trapped, collected plants, gardened and conducted spiritual practices in and around the Red Lake fur trading routes, and traded products obtained in the area.

There are Grassy Narrows families with continuing family ties to this area and the surrounding areas. Grassy Narrows people, including the Chief, continue to practice our inherent and Treaty rights in this area, including the moose hunt. The moose hunt is extremely important to our way of life and sustenance. Due to the precipitous decline in moose elsewhere in our area, the area south of Red Lake is one of the only remaining productive moose hunting grounds that our people use.

The Great Bear Gold Project falls within moose, wolverine and caribou habitat that ranges within our IPCA. In addition, walleye within the project area migrate to the waterways on which Grassy Narrows exercises its treaty rights to fish and on which the community reliese for food. The project area is also within nearby quatermary watersheds that flow into the IPCA.

Grassy Narrows people fish extensively on the English River around Grassy Narrows. Grassy Narrows people also fish on the English River and its tributaries near the inflow of the Chukuni River. We are aware that the fish that we eat swim a distance of 30 km, or more, up and downstream in the course of their lifecycle and are exposed to, and bioaccumulate, toxins throughout their travels. In particular, our walleye travel long distances upstream in order to spawn.

Caribou are an important clan animal to Grassy Narrows and used to be seen throughout our Territory. The Great Bear Gold Project area is within the range of the Sydney Caribou herd, the last remaining herd in our Territory. This range is already degraded beyond the threshold at which it is able to sustain Caribou in the long term, unless its intactness is restored. All of the habitat within the range is considered critical.

As noted above and confirmed by the Supreme Court, the Treaty 3 Commissioner promised the Anishinaabe that the Treaty promises would protect our harvesting practices forever which would allow our people to hunt, fish, trap, gather, and harvest throughout the Territory as they had before “as long as the sun shone and the waters flowed”. The Anishinaabe did not agree to an increasing erosion of our harvesting rights that would significantly interfere with the exercise of our rights.[3]

---

[3] *Keewatin v Minister of Natural Resources*, 2011 ONSC 4801 [*Keewatin* ONSC], rev’d 2013 ONCA 1158, aff’d 2014 SCC 48 [“*Keewatin* litigation”].

Grassy Narrows has a communal connection, right, and interest in this area. It is possible that other First Nations do too, but that does not in any way diminish our own connection, rights and interests nor the Crown's obligations to us.

In addition, Grassy Narrows must be consulted on activities that may have off-site impacts on our territory, such as downstream, downwind, or migratory species impacts. Grassy Narrows continues to document the full extent of its Territory and the "ANA Preliminary Area of Interest With Respect to Mining" is without prejudice to the determination of the full geographical extent of Grassy Narrows' Territory.

The Crown requires Grassy Narrows' consent for the Great Bear Gold Project

The standard that correctly applies to this project is the right to say 'no', also known as the right to give or withhold "free prior and informed consent."

Under Grassy Narrows law, we are the first people of this land. The Creator gave us this land and only the Creator can take it away. We live in relationship with the land; we care for it and the land provides for us. We must take care of the land and not disrupt this balance. Nothing that threatens this balance may take place on the land without our permission. We say no to mining.

The United Nations has recognized this right in the *UN Declaration on the Rights of Indigenous Peoples* and in other international laws and instruments to which Canada is a signatory.

The *Declaration on the Rights of Indigenous Peoples* requires States to consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free, prior and informed consent before adopting and implementing legislative or administrative measures that may affect them (article 19). This includes:

- The adoption of legislation or administrative policies that affect indigenous peoples (article 19)
- The undertaking of projects that affect indigenous peoples' rights to land, territory and resources, including mining and other utilization or exploitation of resources (article 32).

The principle of free, prior and informed consent is linked to treaty norms, including the right to self-determination affirmed in common Article 1 of the International Human Rights Covenants. When affirming that the requirement flows from other rights, including the right to develop and maintain cultures, under article 27 of the International Covenant on Civil and Political Rights (ICCPR) and article 15 of the International Covenant on Economic Social and Cultural Rights (ICECSR), the treaty bodies have framed the requirement also in light of the right to self-determination.

Canada is bound by international law to these abide by these standards.

While Crown law has often failed to adequately implement international human rights standards, and often seeks to take a reductionist view of its international obligations to us, even under Crown law our consent is required for this project for reasons including, but not limited to:

a) The cumulative impacts of Crown policy and industry on our people already exceed any reasonable threshold of impact on our rights, our way of life, our people, and our environment. No further impacts can be made without consent.

b) The Companies' goal is to open a gold mine. A recent study demonstrated the extensive impacts of metal mining contamination on rivers and floodplains across the world, with an estimated 23 million people believed to be affected by potentially dangerous concentrations of toxic waste.[4] Gold mines have high risk of impact to our well established and strong rights, including our rights under Treaty #3. Our waters are already contaminated with mercury. Therefore, we are at the high end of the consultation spectrum where consent is required.

c) The "taking up" clause and the "cede and surrender" clause which the Crown relies on for its asserted legal authority were never explained, translated, discussed, nor agreed to, during the negotiation of Treaty #3. This is reflected consistently in the multiple, independent, written records of the Treaty negotiations. To the contrary, Treaty Commissioner Simon Dawson informed the legislature that "As an inducement to the Indians to sign the Treaty, the commissioners pointed out to them that, along with the land reserves and money payments, they would forever have the use of their fisheries. The point was strongly insisted upon and it had great weight with the Indians, who for some years previously had persistently refused to enter into any Treaty" (NA RG 10 vol 3800 file 48542, 28 May 1888). The Ontario Court of Justice found that the Indigenous signatories to Treaty 3 were not advised and did not understand that the Crown could authorize land uses inconsistent with Harvesting Rights and pass legislation to extinguish or limit Harvesting rights. They expected that Canada would protect their harvesting rights away from the Dawson Route or CPR right or way, not limit, extinguish or ignore them.[5] No court of appeal, including the Supreme Court of Canada has overturned this finding of fact.

Beyond the requirements under Grassy Narrows Law, International Law, and Crown Law to obtain consent in these circumstances, there is the simple practical requirement for consent in today's business, investment, and political environment.

The business case for obtaining consent is reflected in the mining industry's own trade association policies through the International Council on Mining & Metals (ICMM) position statement on Indigenous Peoples and Mining, which states that "[t]he outcome

---

[4] Phys.Org (September 21, 2023), "Global study reveals extensive impact of mining contamination on rivers and floodplains."

[5] Keewatin v. Minister of Natural Resources, 2011 ONSC 4801 (CanLII), at para 865, <https://canlii.ca/t/fmzc4#par865>, retrieved on 2023-09-23

is that Indigenous Peoples can give or withhold their consent to a project, through a process that strives to be consistent with their traditional decision-making processes while respecting internationally recognised human rights and is based on good faith negotiation."[6]

Even Barrick Gold, infamous for their violations of human rights internationally, stated in their $100M statement of claim against Red Lake Gold when addressing the need to for Grassy Narrows' consent that:

> Virtually all successful mining ventures in Canada require a strong and genuine working relationship with local communities, including First Nations. Without such a relationship, it can be extraordinarily difficult, if not impossible, to proceed with a mining venture beyond early stage exploration work and into development work (e.g., by constructing a working mine).
>
> Strong, genuine and reliable relationships with First Nations are built on mutual trust and respect. Any perceived or actual breach of that trust or respect can have devastating consequences for a mining venture or company, and these commercial and reputational consequences can extend well beyond any particular project or First Nation group.[7]

No large mine has opened in Canada for decades without Indigenous consent. It is simply too difficult and risky to carry out such an expensive and intensive project without all relevant First Nations on board.

As a First Nation living immediately downstream from this project, we will live with the consequences for many generations to come. It is our children who will drink the water, eat the fish, pick the wild rice, swim, and learn what it means to be *Asubpeeschoseewagong Anishinabek* on this river whose waters will carry the effluent from this gold mine if it is built. It is our people who will search in vain for moose and caribou to hunt on the landscape that has had its forests fragmented and degraded by access roads, clearcuts, seismic lines, pits, trenches, clearings, and mines. It is our people who will be impacted if the tailings dam fails. It is our people who will be poisoned if toxics leach into the water. It is our people whose fear and anxiety, already far to high and fatal due to the mercury crisis, will be heightened by the threat this mining project poses to our wellbeing.

We know, and everyone in Canada who has cared to learn our story knows, that decisions made and activities carried out upstream can have a devastating impact on us. The chlor-alkali plant in Dryden that discharged mercury into the Wabigoon River was 150 km upstream of our village. But the flow of the river does not obey any human boundaries. The distance did not stop the mercury from being carried downstream,

---

[6] International Council on Mining & Metals (May 16, 2013), "Indigenous Peoples and Mining: Position Statement".
[7] Barrick Statement of Claim against Red Lake Gold, 2022/23, p. 20, 21.

bioaccumulating in the fish that we eat, destroying our livelihood, poisoning our people, and dramatically disrupting our way of life. More than 50 years after the discharge of mercury was ordered halted, our mercury crisis rages on. There is no end in sight to the contamination of our river and to the intergenerational impacts of mercury.

The correct standard for this project, which threatens to impact Grassy Narrows' future for many generations, is consent. Grassy Narrows has not given its consent. Grassy Narrows says 'no'.

Far from seeking consent, Ontario has approved numerous permits for the Great Bear Gold Project with no notice to Grassy Narrows

With respect to the Great Bear Gold Project, there has been a failure to inform, to consult meaningfully with ANA and to gain our consent, even though the ANA village site is the first community downstream from the project site. In spite of the infamous pre-existing impacts on the English River and Grassy Narrows from hydro damming, mercury pollution, and clearcut logging, and Grassy Narrows' well knowns concerns about mining exploration. The fact that Grassy Narrows is downstream of this project, potentially impacted, and likely concerned should be evident to any diligent person with access to Google.

Exploration permits for this project date back to January 2017, including permits for extensive exploration work, drilling, stripping of the land, and taking of water. The following permits were authorized without notice to Grassy Narrows and, for the most part, prior to any communications from either the Crown or the companies with our First Nation:

- January 6, 2017: PR-16-10995 – permit for mineral exploration
- April 11, 2019: PR-18-000295 – permit for mineral exploration
- November 22, 2019: PR-19-000264 – permit for mineral exploration
- November 27, 2019: PR-19-000227 – permit for mineral exploration
- July 16, 2020: PR20-000178 – permit for mineral exploration
- October 13, 2020: PR20-000276 – permit for mineral exploration
- July 13, 2021: PR-21-000190 – permit for mineral exploration
- October 4, 2021: PR-21-000258 – permit for mineral exploration
- August 15, 2022: 5115-CJ9QRR – permit to take water
- September 15, 2022: Permit 5115-CJ9QRR to take water

The failure to take the minimal step of giving notice to Grassy Narrows about any of the above permits is all the more shocking because while this extensive work was being done on the Great Bear Gold Project, Grassy Narrows was writing to Ontario and to the companies seeking to share information and initiate negotiations about protection for Grassy Narrows' lands, waters, and people. Grassy Narrows has written to Ontario repeatedly about land protection concerns for decades, and most recently in a long series of official letters dating back to 2018 requesting a government-to-government table to resolve Lands issues including mining.

The history of communications between Grassy Narrows, Great Bear Resources, Kinross and Ontario's Ministry of Mines demonstrates that none of these parties have demonstrated a genuine intention to meaningfully engage with Grassy Narrows. This summary is current to December 15, 2023:

- **February 25, 2020:** Having learned about Great Bear Resource's presence in the area, but unaware of the permit applications and authorizations, Grassy Narrows Chief and Council wrote to Great Bear Resources to notify the Company about ANA's mining concerns and to ask if Great Bear Resources had any proposed work that would put Grassy Narrows at risk and conflict with our laws. There was no response. Indeed, Great Bear Resources has never responded to Grassy Narrows' communications.

- **October 1, 2020:** Upon learning of Kinross's presence in the area, Grassy Narrows Chief and Council wrote to Kinross Gold Corp. with a request to meet and a list of questions about their work.

- **October 6, 2020:** Chief and Council wrote to Great Bear Resources.

- **October 7, 2020:** Chief and Council wrote to follow up with Kinross.

- **November 2, 2020:** Kinross responded to acknowledge our letter but did not provide any substantive response to our questions, make any mention of the Great Bear Project, nor accept our request to meet. We did not hear from Kinross again for almost two years.

- **December, 2021:** Kinross reached an agreement with Great Bear Resources.

- **August 29, 2022:** Kinross sent a letter of introduction to our Chief.

- **September 15, 2022:** Less than three weeks later, Kinross submitted an exploration permit to Ontario claiming to have consulted with Aboriginal communities.

- **October 4, 2022:** Grassy Narrows wrote again to Great Bear Resources.

- **October 6, 2022:** Grassy Narrows received its first notice of an application for an exploration permit related to this project from Ontario (PR-22-000284). Ontario gave Grassy Narrows only one month to provide comment on the application.

- **November 18, 2022:** With no capacity, and in the midst of the COVID-19 pandemic, Grassy Narrows wrote back to advise Ontario that we intended to respond but could not do so substantively within the time provided.

- **November 24, 2022:** MINES notified Grassy Narrows that Kinross's application (PR-22-000284) had been approved with the exception of 44 claims that were

being held pending further comment from Grassy Narrows but offering no capacity supports.

- **December 28, 2022:** MINES notified Grassy Narrows of seven mining lease applications and advised that MINES would proceed if it did not receive comments by February 26, 2023.

- **January 19, 2023:** MINES notified Grassy Narrows that it was considering granting the mining permit for the 44 claims that had been held, pending comments from Grassy Narrows by February 3, 2023. Again, no capacity supports were offered.

- **February 6, 2023:** Grassy Narrows wrote to MINES to reiterate the barriers to participation that had been communicated over many years; in the absence of addressing those barriers Grassy Narrows cannot engage or comment substantively to the permit applications.

- **February 14, 2023:** MINES gives Grassy Narrows until February 28, 2023 to respond with comments.

- **February 27, 2023:** Grassy Narrows official writes to MINES indicating that Grassy Narrows does want to comment but that further time is required to review the information, and that the company has yet to respond to the questions that ANA has sent them.

- **March 3, 2023:** Grassy Narrows sent a follow up letter to MINES regarding the seven proposed mining leases and Grassy Narrows' requests for a government-to-government negotiation table.

- **March 10, 2023:** MINES wrote to Grassy Narrows to ask for a copy of the questions posed to the companies in 2020.

- **March 20, 2023:** Grassy Narrows wrote to Great Bear and Kinross to request a meeting about the Great Bear Gold Project in early April and for an answer to the questions posed to the company in 2020.

- **March 21, 2023:** MINES followed up on its request for a copy of the questions posed to the companies in 2020.

- **March 31, 2023:** Grassy Narrows followed up with Great Bear Resources and Kinross to request a meeting in early April and to obtain answers to the questions posed in 2020.

- **April 12, 2023:** Grassy Narrows repeated its request for a meeting with MINES and answer to questions concerning Great Bear Resources and Kinross.

- **April 24, 2023:** Kinross finally responds to the request to meet.

- **June 22, 2023:** Kinross attended an introductory meeting with Grassy Narrows. The meeting was not a consultation on the project. Kinross representatives stated that MINES would be providing answers to the questions posed in 2020. Grassy Narrows raised serious concerns about the project, including capacity constraints and concerns about impacts.

- **June 27, 2023:** Kinross wrote to confirm that MINES would be providing answers to the questions posed in 2020. MINES did in fact provide a partial and incomplete response to the questions posed in 2020. MINES gives Grassy Narrows two weeks to provide comment on the 44 outstanding claims.

- **July 12, 2023:** MINES gives Grassy Narrows a further extension to July 27, 2023.

- **July 24, 2023:** Kinross wrote to invite Grassy Narrows to a meeting to learn about the project and to advise that it was setting up a Sharepoint site to share information about the project. The Sharepoint link was not provided. Kinross further advised that the federal impact assessment process had been initiated.

- **July 28, 2023:** MINES wrote to advise Grassy Narrows that Ontario will not provide capacity support for consultation and asked for comments on the 44 claims by August 10, 2023.

- **August 11, 2023:** MINES approves the mining exploration permit for the 44 claims.

- **August 12, 2023:** Kinross provided a copy of Great Bear industrial Sewage Works documentation. Grassy Narrows does not have capacity to analyze or respond to this technical document.

- **September 7, 2023:** Kinross provided a copy of the Great Bear Advanced Exploration Reclamation Strategy for comment. Grassy Narrows does not have capacity to analyze or respond to this technical document.

- **September 13, 2023:** Chief Turtle writes to the IAAC to advise that Grassy Narrows has learned that Kinross and Great Bear have initiated the interim assessment process. Grassy Narrows was not provided notice in accordance with its protocols and demanded that the process recommence in accordance with procedural requirements.

- **September 14, 2023:** Grassy Narrows sent a follow up inquiry to the IAAC.

- **September 15, 2023:** IAAC provided a two-week extension to respond to Kinross's Initial Project Description.

- **September 20, 2023:** Grassy Narrows responded to IAAC by reiterating that the IAAC had not complied with procedural requirements for the pre-planning stage and repeating its demand to recommence the process.

- **September 26, 2023:** Kinross wrote to Grassy Narrows to request a meeting to discuss capacity funding.

- **September 28, 2023:** Kinross wrote to Grassy Narrows to provide two technical documents for comment (AEX Industrial Sewage Application and Aquatics Monitoring Plan; AEX ECA Air and Noise, Emissions Modelling and Dust Management). Kinross offered to meet and provide capacity support.

- **October 4, 2023:** Kinross wrote to Grassy Narrows about a draft permit to take water application.

- **October 6, 2023:** Grassy Narrows Lands Protection Team was given access to the Great Bear Sharepoint site, with extensive technical documents that were not shared previously. IAAC also provided its Summary of Issues for comment and offered to meet.

- **October 20, 2023:** Kinross provided its groundwater monitoring plan for the project and its preliminary mine rock management and monitoring plan.

- **November 3, 2023:** Kinross provided its draft closure plan for comment.

- **November 10, 2023:** Kinross provided its Detailed Project Description for comment. Grassy Narrows met with Kinross and IAAC. Grassy Narrows asked Kinross to pause the impact assessment process until an engagement protocol could be put in place along with capacity supports.

- **November 14, 2023:** Ontario wrote to Grassy Narrows with belated notice that in or around April 2023 it had delegated the “procedural” aspects of consultation on certain matters relating to the Great Bear Gold Project to Great Bear Resources. Ontario’s letter to this effect dated April 6, 2023 was sent to the Chief and not pursuant to Grassy Narrows consultation protocols. Ontario takes the position that the duty to consult is at the “low end” of the spectrum.”

- **November 20, 2023:** Kinross wrote to Grassy Narrows concerning participation in a Stage 3 Archaeological Assessment.

- **December 15, 2023:** Kinross meets with Grassy Narrows and refuses to pause its activities for any length of time to accommodate Grassy Narrows’ unique circumstances.

As the foregoing chronology demonstrates, the companies and Crown left Grassy Narrows in the dark for years about the Great Bear Gold Project. Since September 2023, Grassy Narrows has been flooded with technical documents, belated offers of capacity support, none of which has flowed, and impossible deadlines for engagement.

Kinross spent billions to buy the project and has clearly already decided to build a gold mine regardless of Grassy Narrows' wishes. Failing to engage with Grassy Narrows on this project for more than four and half years was not an error of omission, but rather a deliberate decision not to engage, and to withhold, information about this project from Grassy Narrows. The fact that other First Nations, who are located far upstream of the project, but who have a reputation for welcoming mining activity, were engaged far earlier (as early as 2017), raises the question of whether a decision was made not to engage Grassy Narrows because of Grassy Narrows' well-known concerns about mining exploration.

It took Ontario and the companies nearly three and half years to provide initial responses to questions posed by Grassy Narrows to Great Bear Resources in February of 2020. And yet, within 60 days of providing those initial responses, without providing any capacity support to review them, and without addressing Grassy Narrows' many other barriers and fundamental issues, the Ministry approved further work on the project in spite of Grassy Narrows' request for capacity support and time.

Even Indigenous Services Canada flagged concern about Kinross's level of engagement to date with Grassy Narrows in its comment to the IAAC:

> The perception of contamination to the land, water, traditional food sources and Indigenous Peoples by industrial development may be a serious concern for the identified Indigenous Nations, especially for Grassy Narrows ... During the late 1990s and early 1970s, the English-Wabigoon River system was contaminated with inorganic mercury from a pulp mill located upstream in Dryden, Ontario. This discharge of inorganic mercury contaminated their water and traditional food sources (i.e. fish) and lead to cases of mercury poisoning and intergenerational challenges. The proponent, Kinross Gold Corporation, started engaging with Grassy Narrows First Nation in 2022, whereas their engagements with Wabuskang First Nation and Lac Seul First Nation began in 2017. Due to Grassy Narrows First Nation's negative and detrimental experience with industrial development, it is recommended that more engagement take place. The Indigenous Nations need to gain a greater understanding of the contaminants that may be released into the environment. They should be provided an opportunity to express concerns or uncertainties about potential exposure to chemicals used in the gold mining process, such as cyanide and heavy metals.[8]

Given this history, including the Crown's outstanding obligations to Grassy Narrows, it is highly inappropriate for Ontario to delegate any aspect of consultation to Great Bear

[8] Indigenous Services Canada, Federal Authority Advice Record – Great Bear Gold Project, p. 5.

Resources. Grassy Narrows does not agree that the Crown can delegate its duty to consult with a treaty nation to a third party. Nor does Grassy Narrows agree, given Grassy Narrows' strong rights, existing cumulative impacts, and the companies' intention to open large gold mines upstream from the community, that the duty is at the low end of the spectrum.

The IAAC has failed to consult as required with Grassy Narrows

According to the attached IAAC document summarizing the impact assessment process, the process begins with Phase 0 (Pre-Planning), a phase that requires engagement by both the Proponent and the Agency with Indigenous groups. None of the required pre-planning steps with respect to Grassy Narrows have been complied with.

The Proponent was required to engage Grassy Narrows to present the project, learn Grassy Narrows' views, including potential effects and how we wish to be engaged and to incorporate this information into the Initial Project Description. Grassy Narrows has expressed, both in writing and in meetings on June 22, 2023, and November 10, 2023 with representatives from Kinross, our significant concerns about potential impacts upon our community, which are not reflected in the Initial Project Description. Grassy Narrows also provided Kinross with our communications protocol, which includes communication with the Lands Protection Team. That protocol was not included in the Initial Project Description.

The Agency was aware, based on the Initial Project Description, that Grassy Narrows may be affected by the project. In the pre-planning phase, the Agency was required to inform Grassy Narrows about the impact assessment process to support us in understanding how we can participate. The Agency was obligated to learn Grassy Narrows' views and context, including potential effects and how we wish to be engaged. The Agency did not comply with these requirements of the pre-planning stage.

Crown and Company efforts to engage Grassy Narrows since 2022 have been performative and do not meet the standards required for engagement

The decisions to open our land to mineral staking and exploration, to carry out extensive exploration, and to build a gold mine, have already been made, and billions of dollars spent towards that end, all behind Grassy Narrows' back. In this context, it is hard to believe that requests for belated input at this late stage are sincere. Clearly, the companies and Ontario have already decided to build a gold mine if investors will support it and we are an afterthought.

Kinross is now flooding us with technical documents created by highly paid experts, while knowing that we have no capacity support to engage experts to review the technical documents, nor to engage our community about them. When we sought a pause in the process to gain capacity support, retain experts, complete a process agreement, and engage in our governance process, we are refused. In this context it is hard to believe that anything Grassy Narrows says will be taken seriously and will have

the potential to meaningfully influence the major decisions that have been made.

We live downstream, our established rights and our health are at stake, and we are concerned. Under Crown law the Crown clearly had a duty to meaningfully consult and meaningfully accommodate us at every stage of this project, including during the strategic level upstream decisions (such as land use planning, land use designation, tenure, etc.) as well as the more minor decisions which flow from them (such as specific exploration permits, water takings, leases, etc.). As a First Nation whose Treaty rights and health have already been severely impacted by the cumulative impacts of industry and government decisions our consent is required. Under our inherent rights, Anishaabe law, and International law our consent is also required.

Ontario has failed for many years in their duty to consult on this project and we call for an immediate freeze on all project activities until sufficient capacity support has been provided to allow Grassy Narrows to complete an ethno-historical report, land use and occupancy study, archaeological assessment of the area and study into cumulative impacts, and until we have been meaningfully engaged and our free, prior and informed consent obtained.

V. Adverse Impacts: ANA Preliminary Specific Concerns

As Asubpeeschoseewagong Anishinabek we have a holistic, interconnected, and spiritual relationship to our sacred landscape. We are the land and the land is us. What happens to the land happens to us and to our children for many generations.

This is an area where our ancestors have practiced, and we currently practice our Anishinaabe way of life; a way of life that relies on a healthy environment and is central to our identity, health, wellness, and livelihood. This area is part of the whole that forms the sacred landscape which gives us life and which we are in relationship within every aspect of our lives, hearts, spirits, and dreams.

While some areas may appear to an outside observer to be on the periphery of our Territory, this is a grave misperception. All our territory is core to our way of life and connection to the land. For example, we have always traveled to hunt. A moose that is harvested a few days' travel from our village site will still feed a family for many weeks and be shared with Elders, relatives, and friends. The dramatic decline in the moose population near our village means that the area around Red Lake is even more critical to our moose hunt. These areas are deeply embedded in our memories, our lives, and our hearts. We are strongly tied to this land.

We know that MINES, IAAC and the companies do not respect this relationship and seek to reduce it to a series of finite, bounded sites of 'values'. Our concerns are disregarded unless they are expressed in extremely specific and reductionist terms that ties adverse impacts to particular pieces of the land that are viewed in isolation from the whole. MINES and IAAC want us to engage in an exercise of, for example, identifying a specific hole that is a specific distance from a specific cabin and thus should be moved a bit to the west. Or, this type of machinery produces noise that will make hunting

difficult in this specific blind during this month, so please do not use it in October. Or, this wastewater discharge site is next to that fishing hole, so please put it a bit further downstream.

This approach fails to see the forest for the trees. What use is a remote cabin retreat without the serenity of the surrounding area from which we draw our physical and spiritual sustenance? How can we use it for healing and to teach our children their way of life while over the ridge heavy machinery encroaches ever closer and non-native users buzz around us in ATVs and motorboats? What use is a hunting site if the ancestral moose trails have been destroyed, there is no winter refuge, and unmanaged access routes have allowed non-native hunters to deplete the population precipitously? What use is a fishing spot if the fish has absorbed a dangerous burden of toxins from its food sources everywhere it swims throughout its life, including those carried from upstream? How can we carry out our ceremonies when the spirits who live in the rocks have been disturbed by drilling and blasting. What point is there in commenting on a small drill program in isolation, when everyone knows that your plan is to open a huge open pit and underground gold mine?

In spite of this fundamental difference in world view, the barriers, unresolved fundamental issues, and concerns noted above, we know that MINES, the Companies and IAAC will try to proceed with this project unless we raise specific concerns. In the absence of the necessary supports, Grassy Narrows cannot substantively respond to the technical information provided to date about the Great Bear Gold Project. We provide these preliminary concerns under protest and based upon the limited research we can undertake, which should not be taken as a complete overview of our concerns.

Industrial disturbances will release even more mercury into our ecosystem and further impair our Treaty rights.

The Great Bear Gold Project will require industrial mining exploration, access roads, clearing of trees, modification to water levels and other activity within the English River watershed. The waters from those areas flow into the English River in short order via the Chukuni River. They flow into the areas where we fish, boat, camp, and practice our way of life, and directly past our community.

The scientific literature establishes that industrial activity in the boreal forest releases mercury into local lakes and rivers.

Building machine tracks, trails, and roads is a common part of mining exploration and mine development work. However, simply driving heavy machinery through the boreal forest can contribute to the release of mercury. In one documented instance, a temporary machine track was inadvertently placed across a small, long-term reference catchment. This disturbance increased outputs of MeHg by a factor of over five for more than a decade.[9]

[9] J. Munthe and H. Hultberg (2004), “Mercury and Methylmercury in Runoff from a Forested Catchment -

Clearing the forest has also been found to release mercury into local water bodies where it bioaccumulates in fish to dangerous levels. The foremost study on this subject was completed in Quebec by Dr. Carignan. The study found that 100% of lakes with clearcut watersheds had walleye and pike with mercury levels that exceeded the World Health Organization advisory limit for human consumption. Meanwhile, only 18% of unlogged lakes, and only one burned lake exceeded the limit.[10]

In the only field study on the topic done by Ontario of which we are aware, there was roughly a doubling of mercury exported from a watershed near Thunder Bay via a stream after logging activity. This release of mercury occurred even though all the required regulatory measures, including those with respect to riparian buffers, were followed.

Despite these findings, Ontario does no downstream monitoring of actual industrial operations to monitor or assess mercury impacts.[11]

Both the Carignan and Ontario studies concluded that that the increase in mercury export is largely due to changes in local watershed level hydrology from the loss of tree cover. Mining exploration and mining activity also involve the clearing of trees from the land and risk similar impacts to local hydrology (e.g., Lower evapotranspiration rates, changes to snow and rain interception, etc.) and therefore leads to similar increases in mercury export to local logging.

Mining exploration and mining activities often have the effect of artificially changing water levels. This can happen through water takings, water discharges, dewatering of areas, and other industrial processes. Studies have found that the artificial lowering and raising of water levels in boreal water bodies often causes the release of mercury. Monitoring studies of the De Beers Victor Diamond Mine have found increased levels of mercury in fish in water bodies downstream.

For a more detailed discussion of the science on mercury and boreal forest clearing please refer to our enclosed evidentiary record filed with the Divisional Court in our 2015 Judicial Review Application, and the associated expert reports by Dr. Carignan, Dr. Podur, Dr. Mergler, and Dr. Willow.

Mining exploration and mining activities also risk altering water quality in ways that increase the methylation of existing mercury in downstream watersheds. This can be through the addition of sulfate, change in acidity, water colour, temperature, and other parameters. In Grassy Narrows, where mercury levels are already elevated by emissions from Dryden, any increase in net methylation is intolerable.

Concentrations, Fluxes, and Their Response to Manipulations", Vol. 4 at 607-618.

[10] Globe and Mail (March 12, 2001), "Mercury levels tied to logging practices."

[11] Toronto Star (September 14, 2016), "Ontario environment officials concerned that clear-cut logging releases mercury."

The Crown still has no remediation plan for the mercury that remains in the English-Wabigoon River system from discharges in the 1960s and 1970s. Mercury released into the watershed or methylated as a result of mining activity, especially dissolved mercury, will eventually find its way into the English River and further raise the mercury levels in fish and poison our people, exacerbating and prolonging our mercury crisis.

This is not acceptable. We cannot tolerate any additional mercury.

New releases of mercury or increased methylation will unjustifiably impair Grassy Narrows' treaty rights, health and wellbeing, and are discriminatory. This is an intolerable outcome for our treaty partner to impose on us against our will in the absence of consent.

Adverse impacts on Grassy Narrows' Treaty Land Entitlement Claim.

Grassy Narrows has an active Treaty Land Entitlement Claim (TLE) that has been accepted by the Crown and is under negotiation for resolution. Part of the resolution of the claim will include an addition to Grassy Narrows' reserve lands, and compensation for lost use. Grassy Narrows is currently engaged in a process to select its additional reserve lands. All the area around Grassy Narrows is currently potential reserve lands additions under consideration.

The Crown has asserted that lands which have encumbrances, such as mining claims and leases, will be more challenging to designate as additional reserve lands. This means that your mining claims and leases adversely impact our ability to select reserve land additions and are an impediment to the successful resolution of our TLE.

Further, lands which have been impacted by mining exploration such as cutting lines, pitting, trenching, stripping, and drilling, decline in ecological health, experience a degradation of their intactness, and therefore become less suitable as additional reserve lands.

Lands which are downstream of industrial projects also have their value, and suitability as additional reserve lands degraded. Lands along the shores of the English River and its tributaries have been core to our people for countless generations and are prime candidates for our reserve lands additions. If you were selecting lands for your home, your cottage, or your reserve, would you want a huge industrial gold mine to be opened up stream of them? No one would.

Over the last few decades vast parts of our Territory have been encumbered and degraded through industrial actions imposed on Grassy Narrows and upstream of Grassy Narrows. This has severely restricted the available suitable additional reserve lands.

Grassy Narrows has been clear that there should be no new encumbrances on our area, and no new degradation to our area (including from upstream), as this would unfairly further reduce the available suitable additional reserve lands (in addition to other impacts outlined elsewhere). This would impair the ability to correct the injustice

that was done to us by having been denied a fairly sized reserve for over a century.

On-site Impacts

According to the Ontario Auditor General "Mining activities can have a significant impact on the surrounding environment. They can affect groundwater and surface water, aquatic life, soil, vegetation, wildlife and air quality. The changes mining makes to the environment can have serious implications for public safety and health."[12]

While we are unable to meaningfully review the thousands of pages of technical documents that have been sent to us, it appears that the on-site impacts of the project will be extreme.

Large parts of the site will be deforested for decades at least. Three open pit mines will be created along with three underground mines, large tailings holding areas will be created, and a large ore processing facility will be built.

The project area will effectively be completely removed for the foreseeable future from the land base that is accessible to us to live our way of life and to practice our rights.

It also appears that water bodies including lakes and creeks on the site will be at extremely risk because they will be located immediately adjacent to and downstream / downgradient of heavy industrial operations including mining, ore processing, and tailings storage. We are concerned that the on-site water bodies will be damaged and we know that once they are damaged it can be hundreds, if not thousands of years before they are safe again.

Downstream / wind / migration impacts

We know far too well that industry can have impacts far beyond the industrial site itself. The chlor-alkali plant in Dryden that discharged mercury into the Wabigoon River was 150 km upstream of our village. The distance did not stop the mercury from being carried downstream, bioaccumulating in the fish that we eat, destroying our livelihood, poisoning our people, and dramatically disrupting our way of life. More than 50 years after the discharge of mercury was ordered halted, our mercury crisis rages on.

We fear that the impacts from the Great Bear Gold Project site will extend far beyond the mine site itself, further disrupting the balance of the environment that the Creator has established for us and which gives us what we need for a good life.

Impacts from industrial sites can propagate off site in many far-reaching ways and we cannot list them all here. Pollutants can be carried hundreds of kilometers downstream. Water quality changes that may appear innocuous in themselves, and which are not regulated, can alter the cycling of pollutants, nutrients, and other aquatic processes in damaging ways. For example, dissolved organic carbon (DOC), sulphate, and other

---

[12] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."

substances are a naturally occurring part of aquatic ecosystems and are not considered toxic. However, they known to play a strong role in mercury cycling affecting mercury speciation, solubility, mobility, and toxicity in the aquatic environment. Alteration of water chemistry can have serious consequences.

The wind can carry pollutants and other chemicals long distances before they are breathed by our people and deposited on the ground and in the water. For example, PCBs generated in the industrial centers can be deposited in the arctic and bioaccumulate to levels that are dangerous for subsistence consumers. Acid rain created by the Sudbury mines killed hundreds of lakes for scores of kilometers downstream and the area has yet to fully recover many decades later. We fear that the operation of the mine, including heavy machinery, blasting, and ore processing, will create airborne pollution and changes that can be carried long distances throughout our Territory and beyond, and will compound the existing impacts of other sources of airborne pollution including the Dryden and Kenora mills, other mines, and municipalities.

Off-site impacts can also happen through animals, fish, and birds and other forms of life that travel. If moose can no long find winter refuge on the project site, or if roads, trails and clearings created associated with the project increase access and success for non-native hunters and predators, then fewer moose will be available to hunt. That impact will not be restricted to the boundary of the project site but will extend as far as a moose would range from the project site, or conversely the area from which moose would range into the project site and face predation, hunting, and lack of suitable habitat.

Other animals like wolverine, wolf, bear and cougar travel even further distances. Impacts to their populations, their travel routes, and their hunting success in turn influence the populations of the moose, caribou, rabbits, and other animals that are important to us.

We know that walleye travel large distances throughout their lifespan, especially when they are spawning. Throughout their travels they breath the water, eat the local food sources, and are exposed to local toxins. Many of these toxins stay in the walleye for a very long time and accumulate throughout their lifespan, which can be decades long. As a result, walleye that are not at the project site, nor even within a downstream area impacted by the project site, may migrate into impacted areas and accumulate toxins which we are exposed to when we eat them. In turn, otters, eagles, pelicans and other beings eat the fish and then travel further distances, carrying the toxins with them.

Landscape impacts (e.g. intact forests)

Beyond the on-site and off-site impacts, the project will have landscape-level impacts. Looking at each site in isolation fails to see that the landscape as a whole and its many processes and functions that sustain life. The many parts of the landscape work together, each playing their part. If one is disturbed, then all are disturbed. If too many are disturbed, then the landscape's ability to sustain our good Anishinaabe way of life can be severely undermined.

For example, intact forest landscapes “are critical for stabilizing terrestrial carbon storage, harboring biodiversity, regulating hydrological regimes, and providing other ecosystem functions.”[13] Many species rely on intact forests. For example, the Government of Canada believes that once a landscape exceeds 35% disturbance it crosses a threshold beyond which the landscape becomes unable to reliably sustain a population of woodland caribou and extirpation becomes likely.

Indeed, this is what we experienced in the southern part our Territory where no single project alone caused the local extinction of caribou, but rather it was a death of a thousand cuts as more and more impacts over time made the landscape unable to sustain caribou. We know that the landscape in the range of the Sydney Caribou herd already exceeds this disturbance threshold and is need of recovery. The Gold Bear Gold project will add further disturbance, making the local extinction of caribou even more likely.

Caribou are a sentinel species whose fate is an indicator of the health of the landscape and a range of species and values that rely on intact forests.

Although they behave very differently, moose also rely on a healthy landscape. When there is too much industry, the dense mature conifer forests that moose require for winter shelter become too small, fragmented, and scattered to support moose. When too may roads are put in, outside hunters gain easier access, and when clearings are made those hunters have higher kill rates. When the forest becomes too disturbed, the deer move in, and with them comes sicknesses that hurt the moose.

Again, no one project alone can be blamed for the loss of our moose. But taken together the many industrial changes to our landscape have led to the near elimination of our once healthy moose population.

In spite of our many requests, Ontario refuses to work with us to plan at a landscape level to ensure that our health and way of life can be maintained and recovered. Instead, Ontario allows more and more disturbances to compound each other, further and further degrading the landscape that we rely on. The Great Bear Gold project will further undermine the forest landscape.

Spiritual Impacts

Spiritual impacts are a sensitive topic because it involves some of our deepest and most personal aspects of our selves. It is also sensitive and difficult to share because, not long ago, our spiritual practices were outlawed and we suffered persecution for them. To this day our spirituality is mis-represented, misunderstood, and disrespected by government and industry. For these reasons, this information is only the tip of the iceberg pointing to the presence of a deep and far larger concern.

Our people believe that may aspects of a human being are important to health,

---

[13] Intact Forests, “Intact Forest Landscapes”.

wellness, and the good way of life. A critical aspect is spirituality. The landscape and our way of life are connected and sacred. We have a spiritual relationship of reciprocity with the landscape that requires us to take care of the land so that the land can continue to provide for us. This is a sacred responsibility given to us by the Creator.

Our sacred relationship and responsibility is with the landscape as a whole, and with all of its parts. It is not restricted to a finite set of point values such as ceremony sites, burial sites, and medicine patches. Although those are important, they are focal points in a far broader and all-encompassing spiritual fabric. Our spirituality emanates from, and is infused by the entire landscape. It is practiced throughout the landscape and supported by the entire landscape.

Without the spiritual landscape intact, the spiritual sites are desecrated and cannot function. The medicines do not work if they grow in a clearcut, or if herbicides and pollution have drifted on the wind towards them. How can the ceremony summon a spirit who has fled from the noise of machinery and blasting? How can an offering be made to a spirit-being whose trails and territory have been destroyed? How can the prayer for the success of our hunters be answered when our industrially transformed landscape is nearly empty of moose? How can we fulfill our responsibilities to our clan animals Atik (woodland caribou) and Numeh (sturgeon) when they are extirpated or at risk in much of our Territory? How can we fulfill our duties and ceremonies to the water when it has been polluted, dammed, and an invisible remains within it? How can we identify our grave sites when our people have been laid to rest throughout this land for countless generations?

In addition to our broader sacred relationship with the landscape, there are spirit beings who inhabit the landscape and who have relationships with the Anishinaabe and important roles in the landscape. We have duties to carry out in our relationships with these beings and if we do not fulfill our duties there can be negative repercussions. Some of these important spirit beings live in the rocks. When the are disturbed, hammered, drilled, bulldozed, blasted, or extracted, these spirit beings are impacted, and the spiritual realm is disrupted.

Past government policies and industrial activities have already deeply disrupted our spirituality and the spiritual dimensions of our way of life and wellness. If the Great Bear gold mine, and associated work, goes ahead, then it will have a further intense spiritual impact.

Spiritual impacts lead to bad things for our people. When we cannot fulfill our sacred duties it causes feelings of sadness, anxiety, loss of identity, loss of meaning, depression, and helplessness. When the spiritual realm and relationships are disrupted, it can cause fear, accidents, discord, conflict, bad harvest, unsuccessful hunts, drought, floods, hunger, ill health, and other terrible things.

We understand that the government and industry have a different way of seeing things, and that you see the natural world as separate from you, inanimate, spiritless, and there for the taking. We know that you always tell us that you know best and that the industrial

activities you plan will only cause minor, contained, short term impacts and that we need not worry. And yet, we are suffering from all the terrible consequences that our ancestors warned us would come from your industry and your violation of our spiritual landscape including illness, poverty, hunger, depression, suicide, and conflict.

Our way of understanding the world deserves respect. It is not right for you to force your worldview and all its impacts on us while we suffer the consequences.

Long-term risks – Tailings

We are particularly and deeply concerned by the long-term nature of the changes that you are making to the landscape and the risks that you are creating.

On August 13, 1970, a few months after closing the fisheries due to mercury pollution, the Ontario Minister of the Environment, George Kerr, declared that the Wabigoon River would recover on its own, without a cleanup or intervention. He said it would happen naturally in 12 weeks.[14] More than five decades later, our walleye in the Wabigoon River remain the most mercury contaminated in all of Ontario and it is unsafe to eat even one meal. Recent studies indicate that it will take many hundreds, if not thousands, of years for river sediment to recover on its own. Many sites are not recovering at all, and some are getting worse.

Some of the long-term risks that you are proposing to create include the creation of huge piles of waste rock that contains acid, heavy metals, the creation of new lakes in former open pit mines and tunnelling deep underground. These activities create long-term risks of leaching, groundwater contamination, dam failure, cave ins and falls, among many other things. We know that the impacts of industry can last many generations and for thousands of years.

And yet, our Treaty is only 150 years old. In that time the Crown has shown little ability to plan for the long term in a way that is not disastrous for us. How can we believe that the risks that you are creating will be safely taken care of for longer than Canada has existed as country, for longer than the time that Europeans have been in contact with us? How can we know that Canada, Ontario, Kinross, or Great Bear Resources will even exist in the timeframe that these risks will exist, let alone fulfil your responsibilities to take care of these risks in a way that you never have before?

You say that you will contain, monitor, and prevent these risks from impacting us, our water, and our landscape. But Ontario's own Auditor General has repeatedly found a failure to effectively remediate and monitor mining risks (see the section on failure to regulate below). Senior officials in the provincial government have noted the urgent and dangerous gaps in Ontario's regulatory ability to ensure the safety of tailings dams. You cannot safely carry out these duties now. Who will maintain the tailings dams in 100

[14] The Guardian (October 16, 2018), "The Warrior Society rises: how a mercury spill in Canada inspired a movement."

years? Who will monitor in 200 years?

We, the people living downstream, do not accept these risks.

Impacts to relationship with the Crown

The Great Bear Gold project is a massive one, with great risks to Grassy Narrows and that can have a major impact on many aspects of Grassy Narrows' relationship with the Crown including our Treaty, the honour of the Crown, fiduciary duties, outstanding obligations, unmet duties, and reconciliation.

Yet, the Crown refuses to come to the table with us about the major issues from which all these problems flows. At the same time, Ontario is attempting to delegate nearly all aspects of our relationship with the Crown to a gold mining company that is not party to our Treaty and that is primarily accountable to creating profits for its shareholders. A gold mining company has no ability to address our important issues with the Crown. We do not accept a gold mining company stepping into the shoes of our Treaty partner.

Adding insult to injury, Ontario has informed the company that the duty to consult on this project is at the low end of the spectrum. This is incorrect. For many reasons, even under Crown law, we are at the high end of the spectrum where consent is required. The reasons include but are not limited to the significant potential adverse impacts of the proposed project on our rights and health, the strength of our rights, the cumulative impacts of past industry, the outstanding Crown obligations and unmet duties towards us, the honour of the Crown, and fiduciary duties.

The failures of the Crown have led to a situation where we have been notified of this project only after the land was designated as "general use" and open to mineral exploration, after cumulative impacts of industry had been allowed to severely impact our rights and our health, after mining claims to the land were registered, after five years of exploration work had taken place, after over a billion dollars had been spent to purchase the property, and after the company had decided to open up a huge gold mine here.

The Great Bear Gold project is a runaway train, and we have no meaningful opportunity to shape decisions that will forever impact our people and our land. These decisions include: determining what parts of the landscape should be protected and what should be exploited; the threshold for industrial impacts that can occur before our rights are infringed and our health is harmed; the process for making decisions among Treaty partners; the role of third parties seeking to profit in the Treaty relationship; how to repair harms created in the past but impacting the present; how to prevent future harms; how to reconcile the relationship between the Crown and Grassy Narrows.

The Crown acts as though Grassy Narrows has no say in these decisions. The Crown seems to think that we should accept that a massive gold mine is a foregone conclusion and we should only have a say in things like where the effluent pipe discharges, where the tailings piles are located, and where the processing plant should be sited. We disagree.

This project, the failure of the relationship with the Crown which has allowed the project to become so advanced without our involvement and consent, is having, and threatens to have further major impacts to our relationship with the Crown. Rather than taking a minimal and reductionist view of the minimum that the Crown can do in this situation, a robust understanding of the duties is required, as well as an appreciation for the unique circumstances and history of Grassy Narrows. Only involvement of senior representatives of the Crown can resolve this problem.

Federally Regulated Impacts

Federal involvement is required because of the numerous areas of claimed federal jurisdiction that will be affected by the Great Bear Gold project, including the completion of a Federal Impact Assessment.

Some, but not all, of these areas of claimed federal authority are listed here:

Species at Risk: The Federal Crown claims authority within the Constitutional division of powers over Species at Risk. Although we have not been able to carry out a thorough assessment due to the lack of capacity supports, the project site has a strong potential to impact the following species at risk:

- Woodland Caribou – the project site is within the range of the Sydney Caribou Herd. The range of the Sydney Caribou Herd is currently approximately 64% disturbed (likely higher due to recent fires in Woodland Caribou Provincial Park). This amount of disturbance exceeds the threshold above which the range becomes unlikely to be able to support a viable caribou population. The range is in need of recovery to lower the level of disturbance and therefore the entire range is considered critical habitat. The project will add disturbance, further degrading the ability of the range to sustain caribou and increasing the likelihood that Woodland Caribou, a threatened species, will be extirpated from this area. Caribou is an important clan animal for Grassy Narrows.

  It should be noted that while Ontario does have a *Species at Risk Act*, it has exempted mining and logging from the applicability of that Act. The provincial government cannot be counted on to ensure that the Great Bear Gold project proceeds in a manner that protects species at risk.

- Wolverine – Wolverine play an important and unique role in our ecosystem and in the balance of life. The company has indicated that wolverine have been observed on the project site using trail cameras. Direct observation of wolverines is a rare. Wolverine avoid humans and human impacted areas. The project is almost certain to permanently displace the wolverine that have been observed at the site and to destroy any wolverine dens, trails, habitat, and food sources that are on the site.

  The Committee on the Status of Endangered Wildlife in Canada (“COSEWIC”) reports that wolverines prefer ecologically intact areas and avoid disturbance.

According to COSEWIC "[a] study of the cumulative effects of developments on Arctic wildlife (Johnson et al. 2005) found that mines and other major developments had the largest negative effect on species occurrence, followed by exploration activities, and outfitter camps."[15]

Due to past degradation of southern habitats, wolverine left Grassy Narrows' area. However, our success in stopping logging has resulted in the beginning of a return of wolverine. Grassy Narrows is now near the southern edge of the currently occupied range of wolverine. If the project goes ahead, wolverine will leave our area and may not come back, further disrupting the balance of the landscape.

- Sturgeon – Sturgeon are an important clan animal in Grassy Narrows an important food source for the Anishinaabe of the Treaty 3 area. The damming of the English River has had a big impact on sturgeon. A small and delicate population remains in the river, which we are trying to protect and recover. Sturgeon live for many years, are sensitive to industrial disturbances, and can accumulate large amounts of toxins in their bodies.

There are many other species at risk that may be affected by the Great Bear Gold project, including bats, birds, turtles, Eastern Cougar, American Badger, and others. Each have a role to play in the web of life.

Fisheries: The Federal Government claims jurisdiction over inland fisheries, the prevention of harm to fish from pollution, and the protection of their habitat.

While the Federal Government has cooperative agreements with Ontario for licensing of fisheries the Federal Government maintains jurisdiction and responsibility for prevention of harm and protection of fish habitat.

Under Crown law, even the construction of a small water crossing can trigger the need to apply to the Department of Fisheries and Oceans for permits. In contrast, Ontario does not require a provincial impact assessment before a mine is opened.

We are a river people and fish have always played an extremely important role in our way of life, our sustenance, and our livelihood.

The companies propose to take water from our river system, use it in the industrial gold extraction process, and then return it to our river. The companies propose to create three open pit mines, three underground mines, store large amounts of waste rock and operate an industrial ore processing facility, all in close proximity to water bodies and streams that flow into our river system. Finally, the companies propose to create three new lakes in the empty open pits created by gold mine, and to allow water to flow out of those pits and into other local water bodies. All these activities, and others, put our fish

[15] Government of Canada, "Wolverine (Gulo gulo): COSEWIC assessment and status report 2014" (date modified: January 6, 2015).

at risk.

The Crown has failed to protect our fish for many decades from the impacts of mercury and this has had grave consequences for the rights, health and wellbeing of our people. Given the Crown's failure, and its ongoing impacts, all levels of the Crown should be diligent and alert in carrying out their duty to protect our fish from further harm.

Indigenous Peoples: The Federal Government claims jurisdiction over Indigenous Peoples and the lands reserved for them. This jurisdiction includes claimed authority over our health, culture, and wellbeing, responsibility for environmental contaminants and their impacts on Indigenous traditional foods and on the health of Indigenous Peoples.

The Great Bear Gold project has potential to impact Grassy Narrows' relationship with the Crown, the safety of our traditional foods, and our health, culture, and wellbeing. The project also has the potential to impact waters that flow into and through our reserve and which can impact our reserve.

Due to the Crown's longstanding and ongoing failures to meet its duties to Grassy Narrows, all levels of the Crown should be diligent and alert in carrying out their duty to protect us, our health, our traditional foods, and our further harm.

There are further areas of Federal claimed authority that likely apply here as well and that are at risk in this project, including but not limited to migratory birds, transboundary waters, transboundary air pollutants, international laws and instruments.

Due to the many important areas of claimed Federal authority that are at serious risk in this project, it is essential that a robust and comprehensive Federal Impact Assessment is carried out.

Grassy Narrows seeks to engage with the Federal Government and our consent is required to the form that the Impact Assessment will take.

Site-specific parameters and guidance levels needed

In its Initial Project Description, Kinross states that water, effluent, tailings leachate, and other substances will be tested and will be released back into the environment after they meet guideline levels. However, the Initial Project Description does not identify the guideline levels that will be used. Guideline levels are a very important and complex topic that must be explored in far more detail. Our discussion here is intended to illuminate that there is a serious problem.

Although there are many substances of concern here, we are most familiar with mercury and so we will use it as an example.

There are many guidelines that we have seen applied upstream of our community for allowable mercury levels. Some of these guidelines are wildly inappropriate, but all of them are insufficient.

According to the Government of Canada "(m)ercury is a toxic element and serves no beneficial physiological function in man; a maximum acceptable concentration of 0.001 mg/L (1 µ g/L) in drinking water has therefore been established."[16]

A concentration of 0.001 mg/L corresponds to **1000 ng/L** (nanograms per liter), which is the unit we will use here.

One might think that if the mercury level is good for drinking, then it would be fine to put in our river, but that is not the case. Provincial Water Quality Objectives ("PWQO") are numerical and narrative criteria that serve as chemical and physical indicators representing a satisfactory level for surface waters (i.e. lakes and rivers) and, where it discharges to the surface, the ground water of the Province.

The PWQO guideline level for mercury in surface water is **200 ng/L.**

The PWQO guideline has historically been applied to mercury contaminated groundwater seeping out of the banks of the Wabigoon River next to the Dryden mill to claim that it is safe. However, this too, is irresponsible.

The Canadian Council for Ministers of the Environment (CCME) provides guidelines for mercury levels in freshwater bodies that attempt to account for the risk to fish and wildlife through exposure to mercury.

The CCME guideline level for mercury in surface water is **26 ng/L.**

One might think that if this level of mercury in water is safe for the fish and wildlife, it must be safe to put water with that level of mercury into Grassy Narrows' river. However, the CCME guideline does not consider bioconcentration of mercury as it moves up through the food chain.

As the Government of Canada explains "[t[he presence of mercury in water has become a source of concern because of the finding that organic mercury is bioconcentrated by fish. Elevated mercury levels have been found in all freshwater fish taken from areas with suspected mercury contamination and frequently render the fish unacceptable for human consumption."[17]

The mercury levels that are found in predatory fish like the walleye, can commonly be a million times the level that is found in the water that they swim in.

Recent monitoring studies of the Wabigoon River upstream from the Dryden mill show that **baseline level of mercury in the Wabigoon River is around 1 ng/L.** Even at those baseline levels of mercury in water, large adult walleye in Wabigoon Lake often exceed 0.5 ppm mercury, the level above which the commercial sale of fish for human

---

[16] Health Canada (1986), "Healthy Living: Water and Mercury."
[17] Health Canada (1986), "Healthy Living: Water and Mercury."

consumption is banned.

If the level of mercury in the River is raised to **2 ng/L**, then mercury levels in adult walleye will approximately double, making them far more dangerous to eat. If other chemicals that stimulate net methylation in the environment are added as well, then the effect will be even more grave.

That means that river water with 2 ng/L of mercury will have serious impacts on the health of Grassy Narrows people's ability to safely practice their right to fish, even though this level is less than 10% of the level allowed by the CCME guideline, the most restrictive of the guidelines we are aware of.

A similarly broad range of guidelines exist and are applied for mercury levels in fish safe for human consumption.

The Ontario Ministry of the Environment "Guide to Sportfish Consumption" allows for some consumption of fish by the non-sensitive population (adult men and women who are not of child bearing age) if the fish have mercury levels below **1.8 ppm.**

On the other hand, the sale of fish for human consumption in Canada is banned if the fish have mercury levels over **0.5 ppm**. Grassy Narrows fishermen have been charged for selling their catch based on this rule.

In the 1980s, Canada established **0.2 ppm** as the guideline limit for safe consumption of fish by Grassy Narrows and other Indigenous subsistence eaters of fish.

The US Environmental Protection Agency ("EPA") lists **0.1 ppm** as their guideline level for Indigenous subsistence eaters of fish.

Renowned mercury expert Dr. Mergler has written in expert reports (some of which are enclosed), all of which have been provided to Ontario, that among these guidelines the US EPA level is most relevant to Grassy Narrows. However, she notes that all these guidelines are based on safe levels for a lifetime of exposure in a regular population. Mercury impacts are cumulative throughout the lifespan. None of these guidelines take into account the high, and far above guideline, levels of exposure that many Grassy Narrows people have already been exposed to. She writes that Grassy Narrows people have generally already been exposed to too much mercury and cannot safely be exposed to any additional mercury.

Clearly, off-the-shelf guidelines are not sufficient. It is necessary to develop and apply in close collaboration with Grassy Narrows locally specific guidelines that take into account the local background levels, ecology, food chain, cultural practices, and cumulative impacts from other industry, and history of exposure.

Other specific concerns

Given the constraints that we have noted, it is not possible to provide a comprehensive list of concerns here. However, some further concerns that we have identified to date,

which will require future elaboration, include:

- The contamination of the water within our Territory and water that flows into our Territory from effluents, discharges, by-products, leaching (including of metals), and changes in mercury cycling
- The creation of acid rock drainage and other forms of toxic drainage
- Changes to the flow, level, and quality of our water from water takings and discharges.
- The contamination of our air and air that flows into our Territory
- The loss of our caribou and moose, and of those who travel into and out of our Territory through impacts including habitat degradation and outside hunting pressure
- Disrupting the delicate balance of animals, predators, prey, and the web of life that supports us.
- The contamination and loss of our fish for food, commercial fishing, sport fishing, and way of life, including fish that migrate in and out of our Territory
- The loss and contamination of our birds and insects including migratory birds
- The loss of our valuable fur bearing animals including marten and otter
- The fragmentation and degradation of our forests and the loss of intact forest landscapes and old growth forest areas
- The changing of mercury exports and mercury cycling, including methylation
- The creation of additional anxiety, fear, depression, disempowerment, and despair among our people
- The further disruption of our society, our culture, and our way of life.
- The exacerbation of our suicide crisis
- The desecration of our sacred landscape
- The disturbing of spirits and beings that live in the rocks
- The tainting of our medicines
- The disruption of our people who are out on the land living their way of life
- The loss of peace and quiet for our people who are out on the land

- The loss of the ability to use the land as a healing place for our people
- The loss of our ability to teach our kids our way of life, identity, knowledge, and ways of wellness
- Impacts to our individual and collective health and wellbeing
- The loss of our ability to make a living in a way that is harmonious with our culture
- The violation of our Indigenous laws and jurisdiction
- The violation of our Treaty rights, our Treaty relationship
- The violation of the honour of the Crown and Fiduciary duties.

Other harmful impacts of industry on ANA people and Territory include, but are not limited to, the following:

- Impacts to game animal populations and their habitat including moose, and caribou which are central to our hunt and an important part of our way of life, our sustenance, our livelihood, and the exercise of our Treaty rights;
- Impacts to fur bearing animal populations and their habitat including pine marten which are central to our trapping and an important part of our way of life, our sustenance, our livelihood, and the exercise of our Treaty rights;
- Changes in forest composition including a shift from extensive coniferous dominated stands to fragmented deciduous dominated stands;
- Failure to regenerate forests or failure to regenerate to their previous composition;
- Loss of productive land base through tertiary roads, machine trails, landings, mines, tailings, buildings, erosion, etc.;
- Loss of species and genetic diversity;
- Loss of shrubs, including berries and medicines including through the use of herbicides;
- Tainting of our medicines and rendering areas unfit for sacred medicine harvesting and ceremony;
- degradation of forest soils, including compaction, rutting, scarification, and erosion;

- Disruption of nutrient cycles including the depletion of calcium in our watersheds, leading to calcium deficiency in aquatic biota;

- Increased competition with non-Indigenous hunters and fishers using forest access roads and associated depletion of animal and fish populations;

- Increased road traffic and danger of collision of people and wildlife with forest industry vehicles;

- Loss of traditional travel routes, sacred places, heritage, and archaeological sites;

- Negative impacts on water quality, fish habitat, fish populations, and fish contaminants;

- Risk of increased violence against ANA people, including gender-based violence, from an influx in workers coming into the Territory to log, and the potential establishment of man camps;

- Lack of recognition of cultural Anishinaabe way of being;

- Violation of our inherent, Treaty, and Aboriginal rights; and

- Violation of ANA Law and the will of our people.

Failure to Effectively Regulate and Remediate

According to the Government of Ontario, there "are over 5,700 abandoned mine sites in Ontario that have over 17,000 mine features, known as hazards… Deaths due to mine hazards in Ontario are rare, but deaths happen in North America every year."[18]

As of 2015, only four mines were listed as fully closed out. Only three are identified as undergoing remediation. On the other hand, there were 56 abandoned mines with 629 contaminated sites meeting provincial criteria for liability recognition. A further 306 abandoned mines had over 3,000 contaminated sites that do not meet the criteria for liability recognition.[19]

There are already many abandoned mine sites in our Interim Area of Interest for Mining, mostly in the Red Lake Area, many of which have been left in an unremediated state for decades. A number are classified as dangerous by the Ministry.

According to the Ontario Auditor 2015 report, the Ministry of Mines has not estimated

[18] Ontario, "Abandoned mines hazards" (last updated February 17, 2023).
[19] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."

the total cost of rehabilitating the 4,400 abandoned mine sites in Ontario since 1993 and therefore does not know the current cost for doing so. It also does not have a long-term plan for rehabilitating these sites. These sites may pose risks to public health and safety and the environment.[20]

The Auditor General found that the "Ministry conducts minimal inspection and follow-ups on abandoned mines."[21] In the five years before the audit "the Ministry has inspected only about 6% (248) of abandoned mines to ensure that they do not pose a risk to public health and the environment."[22]

The Crown often assures us that despite the legacy of past bad practices, mining regulation is done safely now. To the contrary, the Auditor General found many glaring flaws in Ontario's regulatory regime for current mining, including that "Ontario is the only province in Canada that does not require a provincial environmental assessment to be performed for mining projects."[23] The Auditor General's report further explained that "in Ontario, the *Mining Act* only requires mining companies to submit closure plans prior to the development of the mine… In other provinces in Canada, larger mining projects automatically trigger a provincial environmental assessment."[24]

The Auditor General found that the closure plan process lacks sufficient funding, is subject to pro-industry bias, plans are not updated, and inspections are insufficient to ensure safety.

As of 2022, the government had not inspected nearly half of Ontario's operational mines since 2011.[25] The news media has also reported that Ontario senior officials are highly concerned that following several recent tailings dam failures "there is little to no legislative authority to prevent similar situations from occurring in Ontario."[26] According to the media the regulatory gap is outlined in a section of a briefing binder for Minister Pirie dedicated to "critical decisions. Senior bureaucrats, who told Minister Pirie that the gap in offline tailings dam rules was a "high-risk gap in the regulatory framework that requires urgent attention."

Far from improving the overall mining regulatory situation, the Government of Ontario has recently watered down its regulations with respect to requirements for closure planning and closure funding through the *Build More Mines Act*. The Act gives the Minister extremely broad discretion over nearly all aspects of mining including closure planning and funding. Under the new rules the position of Director of Mine Rehabilitation

was removed, Ministry staff no longer review closure plans and instead industry staff may carry out the review, contrary to the Auditor's 2015 recommendations.

Given this context, Grassy Narrows does not trust that the appropriate regulations are in place to ensure mining sites will be kept safe for many generations to come. You have not earned our trust.

Lack of Protected Areas, Need for Regional Balance.

There is an imbalance in the region because nearly all forests south of Red Lake are open to industrial mining. For example, much of our Territory is in ecodistrict 4S-2 where only 4.1% of the ecodistrict is protected. Part of our Territory is in ecodistrict 4S-3 where only 3.3% of the ecodistrict is protected. The lack of protection for our landscape is the clear outcome of an unbalanced landuse designation process that did not involve us meaningfully and ignored our rights and interests.

In contrast, conservation biology generally dictates that at least half of an ecosystem must be protected to avoid loss of biodiversity and ecosystem functions. Ontario has committed to community-based land use planning in the Far North based on a joint planning process between the First Nations and the province.[27] It committed to protecting 50% of the landbase in partnership with First Nations following First Nations-led landuse planning.

Canada has committed to protecting 30% of the land in Canada by 2030 in partnership with First Nations. Respecting ANA's efforts to protect our environment will contribute to the maintenance and recovery of biodiversity and ecosystem functions and will support a balance in this region, where the vast majority of forests have been open to industrial logging and mining.

Nature Based Climate Change Solutions

Climate change and biodiversity loss are major threats to Grassy Narrows and to the world. Nature based solutions have been identified as an important part of preventing and mitigating both problems. The boreal forest is one of the world's largest storehouses of carbon. After logging or clearing of the land for mining, much of this carbon is released from the forest, plants and soils, contributing to climate change. On the other hand, protecting forests helps to keep the carbon safely stored and safeguards biodiversity. These are important ecosystem-based services that contribute to mitigating climate change and that have a significant value.

Fighting climate change and biodiversity loss are important priorities for Grassy Narrows and for Canada and respecting Grassy Narrows' land protection will contribute to progress on these priorities.

---

[27] *Far North Act, 2010*, SO 2010, c 18.

VI. Mining activity without Grassy Narrows' consent risks conflict

Barrick writes that "[a]ny perceived or actual breach of … trust or respect can have devastating consequences for a mining venture or company, and these commercial and reputational consequences can extend well beyond any particular project or First Nation group." In so writing, Barrick raises the spectre of conflict minerals, also commonly knowns as blood minerals.

Global concerns about unethical practices by mining companies, including Canadian gold mining companies, have led to increased scrutiny of the social, environmental, and ethical practices of mining companies. For the mining industry, the problem with conflict minerals is that no one wants them. Conflict minerals are hard to market, and they increase corporate risks and uncertainties associated with investment, timelines, regulatory approvals, litigation, social conflict, and brand damage.

As a consequence, Ontario and Canada have sought to market themselves as stable, safe, ethical, jurisdictions from which to source conflict-free, or ethical minerals. While there are cheaper jurisdictions in which to operate, the conflict-free reputation of Ontario and Canadian minerals is a significant competitive advantage relative to many of other global mining jurisdictions.

However, as Barrick noted, for the mining industry and a mining jurisdiction, trust is hard to gain and easy to lose. It only takes one high profile conflict to taint an entire company, a sector and an entire jurisdiction and to undermine decades of marketing.

Ontario learned this lesson in the analogous conflict with Grassy Narrows over unwanted logging. After decades of unliterally forcing clearcuts on Grassy Narrows against their will, the First Nation turned to protests, boycotts, media campaigns, public education, litigation, and grassroots blockades. Within six years, major sourcing contracts were being threatened and shortly afterwards Abitibi, the world's largest newsprint producer, withdrew from Grassy Narrows Territory.

The City of Kenora, in their 2009 report to the Ontario Good Roads Association / Rural Ontario Municipalities Association, wrote that "[t]he issue with Grassy Narrows on the Whiskey Jack Forest must be resolved... Without resolution of these issues, **the wood coming off the Whiskey Jack Forest cannot be sold**. **There is no current customer willing to accept wood products from a forest unit which is involved in a perceived controversy."** (emphasis added)

This dynamic is beginning now with respect to mining. A long and growing list of mining companies, including Barrick, Trillium, Bounty, and Kenorland have voluntarily committed not to explore without consent or have left the area. Their withdrawal reflects an enduring reality in the mining industry where compliance with international law, third party certification standards, customer, investor, and shareholder expectations, and social license preclude the use of conflict minerals.

The Crown would be wise to avoid instigating conflict with Grassy Narrows again by approving unwanted mining. Controversy with Grassy Narrows about one mine could

taint the reputation of Ontario as a conflict-free place to mine. It could give the entire regional industry a stain that heightens risk and uncertainty and discourages investment throughout the supply and production chain.

The entire region and industry benefit from an environment free of conflict. It is in the interest of Ontario and industry to resolve, not inflame, the conflict with Grassy Narrows.

VII. Gold does not justify the impact to Grassy Narrows

Gold does not serve an essential and irreplaceable function in society. The largest use of gold by far is for jewelry, followed by investment and central banks demand. Technology, a distance fourth, used only six percent of gold production in 2022 (309t out of 4,721t produced globally). Much of that technology is electronics with short life spans and abysmal recycling rates.

Because gold is not essential, but is valuable, the rationale for mining gold by Great Bear and Kinross is purely financial. Shareholders demand a return on their investment, but Ontario need not repeat the mistake of sacrificing Grassy Narrows' rights and wellbeing for the interests of corporate shareholders.

The flow of resource wealth has been used to justify the damming of our river, dumping of mercury, logging of our trees, and now proposed gold mining. The impacts we have suffered from this approach are extreme and ongoing. The mine is projected to operate for a mere 25 years, but we will be here for many generations. No longer can the Crown and third-party companies seek to sacrifice our health, way of life, livelihood, rights, and environment for short term shareholder gains. Enough is enough.

It is important to remember that it is tourism, recreation and services – not resource extraction – that now forms the backbone of Kenora's employment. This shift is not due to a lack of available wood or minerals, but rather reflects increasing mechanization and marginal profitability in the extractive sector in contrast to the growing demand and labour intensiveness of the non-extractive sector. Grassy Narrows' work to protect our landscape and our environment have helped to foster Kenora's greatest economic strength.

The Kenora and Red Lake area enjoy substantial benefits for tourism, wildlife, hunters, fishers, trappers, recreational users, and non-extractive industries. According to the municipal website "[t]he City of Kenora has transitioned from a pulp and paper mill town to a destination and lifestyle community."[28]

The tourism and services industries are Kenora's largest employers by far. The visitor and cottager sectors contribute $300 million annually to the Kenora economy. In contrast, it is estimated that the Weyerhaeuser mill contributes $60 million to the local economy, even when counting indirect economic benefits throughout the region.

---

[28] City of Kenora, "Key Industries" (accessed January 23, 2021)

Kenora's tourism labour force makes up 38% (3,314 jobs) of Kenora's total employment, while Tourism related occupations account for 51.5% (4,405 jobs) of Kenora's total employment.[29] The growth of this industry is key to Kenora's economic plans.

According to the current Whiskey Jack Forest Management Plan ("FMP"), "[t]here are numerous tourist operators in the Whiskey Jack Forest. The recreational activities provided by these outfitters include options for fishing, hunting, camping and other eco-tourism opportunities. The number of individuals, residents and non-residents, procuring services from these tourist establishments are numerous, and they contribute a significant amount of economic resources to local communities ... The Sunset Country Economic Study reports that in 2001, 443 operators provided employment to 3,785 persons of which 1,221 were located in the Whiskey Jack Forest".[30]

In contrast, the Evolution gold mine in Red Lake employs 740 people, only a sixth of the number employed in tourism related jobs in Kenora and is chronically at risk of shutting down if profitability cannot be increased for its Australian owner.[31]

As set out in the Lake of the Woods Tourism Sector Report, "[o]ngoing investments in tourist services and resources only compliment the pristine natural environment that has attracted visitors to Lake of the Woods for over a century."[32]

The current FMP notes that "public and municipal officials should be aware that provincial parks help to make their communities attractive for business as well as for tourists and retirees. The retirement community brings in pension income, which is often indexed to inflation and is "recession proof'.[33]

Respecting and supporting Grassy Narrows' efforts to protect the landscape would contribute to the region's tourism economy and maintain opportunities to grow that economy as well as to become a leader in the conservation economy through future protected areas and associated eco-tourism attractions. A conservation economy creates long-term sustainable employment potential for local and regional residents by maximizing existing skills and knowledge.

VIII. A Choice, an Opportunity

Our youth are crying out. They want to see the land protected so that we can use it to heal our people and our spirits. This is reconciliation for us. They deserve to see the light at the end of the tunnel. We do not want to have to fight, again and again, to protect out land.

However, the community of Grassy Narrows is strong. We know our history, our rights,

---

[29] LOTW Tourism Sector Report (2017), pp. 37, 38.
[30] Whiskey Jack Forest FMP 2012-2022, p 95.
[31] CKDR 927 FM Dryden (June 19, 2020), "114 Layoffs at Red Lake Evolution Mine."
[32] LOTW Tourism Sector Report, 2017.
[33] Whiskey Jack Forest FMP 2012-2022, p 98.

our language, our teachings, and our way of life. We have allies across the country and across the world. The days of forcing harm on us against our will are over.

Respecting Grassy Narrows' land protection is the best available way to minimize conflict and move towards a path of reconciliation and respect for our inherent, Aboriginal and Treaty rights in compliance with international Indigenous rights standards.

Grassy Narrows has borne the brunt of the impacts of industry in the region, while our voice has long been ignored by Crown and industry decision makers. Part of the outcome of this mistreatment has been conflict over logging and one of Canada's most infamous environmental poisoning sagas. As a consequence, the region, and the country, has a stain on its honour, its reputation and credibility.

Times have changed. It is no longer acceptable, nor viable for the Crown to approve extractive industrial activities without Indigenous parties' consent. Across Canada there is a commitment and an expectation for reconciliation. We have an opportunity now to learn from the mistakes of the past and to heed the voice of Grassy Narrows. In the process, we can move from conflict to cooperation, from destruction to restoration, from harm to hope. Grassy Narrows invites the Crown to join us in righting this historical wrong. Respecting Grassy Narrows' land protection would be an important show of good faith that would be a positive step on the path towards reconciliation.

The Crown is at a crossroads.

On the one hand, the companies are proposing to open a large and toxic gold mine upstream from us against our will. If implemented, the mine risks irreparable harm to Grassy Narrows' rights and interests including, but not limited to, harms caused by cumulative effects, neglected obligations, Treaty infringement, harm to our health, release of mercury, and loss of way of life and livelihood. This harm would be immoral, unjustified, unreasonable, dishonourable, and a breach of Ontario's fiduciary duties to Grassy Narrows.

On the other hand, respecting Grassy Narrows land protection would have a beneficial impact on the exercise of Treaty rights and on the environment, cause no harm to anyone's health, and be beneficial for the growing non-extractive economy. There is an opportunity for calm that will allow ANA and the Crown to focus on long-term resolution of our issues and that will help ANA return to the health, self-determination, and prosperity that we once enjoyed.

We are inviting you to walk with us on the path of protection, healing and reconciliation. Will you work with us, or against us?

APPENDIX A

INTERIM Issues for Negotiation/Engagement/Consultation with MINES

August 18, 2023

1. Recognition and respect for ANA inherent, aboriginal and Treaty rights
2. Recognition and respect for the ANA Land Declaration
3. Recognition and respect for the ANA IPCA
4. Harmonization of Crown Law and ANA Law with respect to mining related activities
5. Repairing the Crown – ANA relationship with respect to mining related activities
6. Outstanding Ontario obligations to ANA including those arising out of the 1978 MOU and subsequent commitments such as increased ANA control and ownership over its land base
7. Land-use redesignation of the ANA IPCA
8. Interim measures including the withdrawal of the ANA IPCA from staking
9. Suspension of all mining exploration activities on the ANA IPCA and vicinity
10. Resolution of existing third-party mining interests on the ANA IPCA created by the Crown
11. Issuing a Notice of Caution for mining related activities on lands where ANA rights and interests could be impacted
12. MINES Minister's unfulfilled commitment of November 2021 to visit Grassy Narrows to discuss mining issues in an open forum.
13. Cumulative impacts of past mining related activities on ANA
14. Cumulative impacts of mining activities and other industrial and crown policy impacts on ANA including mercury
15. Resolution of issues arising from past mining related activities which have occurred without ANA consent (restoration, compensation, apology, etc.)
16. Ending Free Entry mining exploration and resolving the issues it has created
17. ANA concerns re off-site impacts and risks of existing mining activity (e.g. at Red Lake and Goliath mines, Red Lake and Separation Rapids exploration) on ANA
18. ANA concerns and MINES failure to take into account risk of off-site impacts of proposed mining exploration and other mining related activity on ANA (including downstream, migratory, downwind, landscape level, and other impacts)
19. Addressing ANA concerns re: Changes to the Mining Act
20. Addressing ANA concerns re: Regulation and enforcement of tailings management
21. Impacts of mining related activity on mercury mobilization and cycling
22. Impacts of mining related activity on Intact Forest Landscapes and associated values and ecosystem functions
23. Impacts of mining related activity on source water protection and source water planning and management
24. Impacts of mining related activity on moose, caribou, marten, fish, and other wildlife
25. Impacts of mining related activity on ANA sacred landscape, spirituality, ceremonies, medicines

26. Impacts of mining related activity on ANA land based healing
27. Impacts of mining related activity on ANA travel routes, camp sites, occupancy sites, burials, etc.
28. Impacts of mining related activity on ANA archaeological and historical values
29. Impacts of mining related activity on ANA safety, and risk of racial and gender based violence including man camps.
30. Unanswered correspondence from ANA to MINES and Ontario
31. Barriers to meaningful ANA engagement including the ongoing Mercury Crisis, housing crisis, water crisis suicide crisis
32. Reimbursement of past ANA expenses for unfunded engagement with the Crown and mining companies.
33. Capacity support required by ANA to begin meaningful engagement
34. ANA Consultation Area with respect to mining
35. Proposed and existing mining exploration and other mining related permits

Asubpeeschoseewagong
Netum Anishinabek
GRASSY NARROWS, ONTARIO P0X 1B0 • PHONE: (807) 925-2201 • FAX: (807) 925-2649

March 26, 2024

Attention: Trina Rawn (Director, Mineral Development Branch)
Ministry of Mines
933 Ramsey Lake Road, B6
Sudbury, Ontario P3E 6B5

Dear Trina Rawn:

RE: Great Bear Gold Project – Advanced Exploration Permits

Further to our meeting on March 19, 2024, we understand that MINES is considering a suite of permits for extensive activities at the Great Bear Gold Project site within our Interim Core Area of Interest for Mining.

We have informed you many times about the unique circumstances and extreme barriers that Grassy Narrows faces that prevent meaningful engagement until these barriers have been addressed. In the interim, we fear that you will move ahead without us, so we share this preliminary information.

The activities that are being proposed as advanced exploration for the Great Bear Gold project appear to be extensive and likely to have very serious impacts on our rights and interests both on and off the project site. While the activities have been called “advanced exploration” by MINES, what is in fact proposed is better described as a proposal to open a small to medium sized mine. Large amounts of overburden, waste rock, and ore would be removed. Waste rock would be stored on site long term. These activities are likely to have significant and adverse impacts to water, including the risk of mercury methylation as substances such as sulfate interact with the mercury already in the river system.

Based on our preliminary review of the advanced exploration application materials, it appears that there are significant gaps in information and unanswered questions concerning the types and levels of substances that will be released into the environment as a result of the bulk sampling process as well as the impact that these substances will have on fish, wildlife and the Grassy Narrows community downstream. ANA requires expert advice to fully assess the permit materials.

However, it is apparent that ANA's meaningful consultation and free, prior, and informed consent is required.

ANA requires substantially more time, and capacity support, to be able to meaningfully review and respond to these proposals. We caution you not to interpret our inability to respond in detail to the proposals yet as a lack of concern. We urge you not to make a decision about these proposals before we have completed our review and been meaningfully consulted and our free, prior, and informed consent has been obtained.

The process with respect to these proposals to date has been fatally flawed, including as a result of MINES' erroneous assessment of the strength of the duty to consult with Grassy Narrows about these permits as 'low'; the delegation of most consultation activities to Kinross, and approval of Kinross' consultation plan designed on the basis of a 'low' strength of duty to consult.

At our meeting with MINES officials on March 20, 2024, we learned the following information:

1. When making the 'low' scoping determination, MINES did not seek any information nor input from Grassy Narrows about the nature of our rights and uses in this area.
2. Prior to Grassy Narrows' recent Judicial Review application about 9 mining exploration permits, MINES had never asked Grassy Narrows what our "area of interest" with respect to mining is, nor what the extent of our Territory, the area we practice our rights on, or what our "consultation area" for mining is.
3. When making the 'low' strength determination MINES erroneously believed that that Grassy Narrows people do not use the project area and vicinity for the practice of our rights. This was based on the reasons provided in your recent correspondence, including that Grassy Narrows had not objected to earlier exploration activity on the site in a context in which MINES failed to provide notice or seek to consult with ANA.
4. MINES has assessed that the proposed work, including the extraction of a bulk sample, long term storage of waste rock and tailings on site, taking water from the Chukuni River, and discharging treated wastewater into the Chukuni River, had "very low to negligible" risks of impacts to the environment.
5. MINES is in the process of re-assessing the strength of the duty to consult in this instance.
6. MINES remains unwilling to negotiate with Grassy Narrows about cumulative impacts, outstanding obligations, increased control over landuse, which activities are appropriate for which parts of the Territory, and other issues raised by ANA except for Mining permit applications submitted by proponents and Capacity Funding sufficient for one Mining Advisor community staff position.

7. The process that MINES and Kinross are using to engage Grassy Narrows is the same as that which would be applied in any part of Ontario and does not take into account Grassy Narrows' unique circumstances.

In fact, the following contrary information should have been apparent to MINES, and would have been abundantly clear to MINES if it had engaged meaningfully with Grassy Narrows:

a. The project area and vicinity are part of the area where Grassy Narrows people hunt for moose.

b. Grassy Narrows' ancestors have used this area and vicinity since before the time of the Treaty.

c. Grassy Narrows is the first community downstream of the project site.

d. Grassy Narrows has already suffered intense cumulative effects and cannot bear further impacts.

e. The Crown has outstanding obligations to Grassy Narrows under International Law, the Treaty, the Charter, and commitments made by the Crown to Grassy Narrows.

f. The proposed work is extensive and has the potential for high impacts to the environment that Grassy Narrows people rely on both on-site and off-site.

g. The project documents do not contain sufficient information to allow Ontario, as the regulator, to fully quantify and assess the full range of impacts that the project will create, nor to allow Grassy Narrows to fully evaluate the impacts on our people and our rights.

MINES' erroneous determination that the duty to consult with ANA was "low" was based on inadequate information, did not involve communication with Grassy Narrows, and therefore used false assumptions and shoddy interpretation that lead to an unreasonable decision.

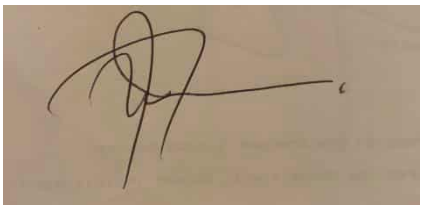
All of the engagement with Grassy Narrows on these permits to date has been fatally flawed because, among other reasons, it has been based on the erroneous determination of a 'low' strength of duty to consult.

The decision-making process on these permits must be halted and re-started with proper information and process. The strength of the duty to consult must be re-assessed. The decision to delegate consultation to the proponent must be reconsidered. The consultation plan must be re-written in light of the information Grassy Narrows has provided about the strength of its claim and information it intends to provide (subject to capacity) about the potential adverse impacts.

The barriers preventing Grassy Narrows' meaningful participation must be resolved, including unresolved foundational issues, the mercury crisis, lack of capacity support,

and lack of sufficient time. Grassy Narrows must be meaningfully consulted and our free, prior, and informed consent must be obtained.

Sincerely,



Joseph Fobister

Lead Land Protection Negotiator for Grassy Narrows First Nation.

Attn: Grassy Narrows Lands Protection Team

Dear Grassy Narrows Lands Protection Team,

RE: Great Bear Mining Project Owned by Kinross Gold - Initial Comments on ML-ARD and Contaminant Source Terms for the Proposed Mine Plan

Introduction

I understand that the federal impact assessment of the proposed mine plan for the Great Bear Mining Project in Ontario will start soon. There are major issues and a major lack of information that should preclude the environmental assessment from starting at this time, as explained below. This includes the proposed large Advanced Exploration which itself could have significant environmental impacts as explained below.

The Impact Assessment Agency of Canada (IAAC) explains on its website:

> *"The assessment considers potential environmental, health, social and economic impacts of proposed projects, including benefits. Potential impacts on Aboriginal and treaty rights are also assessed and consulted on. The Agency or review panel uses the information to develop an impact assessment report."*

My focus here is purely environmental. Nevertheless, I realize there are some strong environmental connections to health, social, and economic. Thus, my comments below may also be relevant to these other portions of impact assessment.

Please note my qualifications for making the comments below include the following. I have been assessing water contamination at minesites by metal leaching and acid rock drainage (ML-ARD) for 46 years. I have done this at several hundreds of exploration, operating, and closed mining-related sites on all continents except Antarctica, from north of the Arctic Circle to south of the Tropic of Capricorn, in biogeoclimatic zones ranging from virtually no annual precipitation up to a rare daily

rainfall of one meter. I earned my Doctor of Philosophy degree in contaminant hydrogeology from the University of Waterloo, where my supervisor was the renowned Dr. John Cherry along with a thesis committee including Drs. Emil Frind (a well-known groundwater modeller) and Eric Reardon (a well-known geochemist). To date, I have authored or co-authored 99 published papers and presentations, five books, and 80 online case studies. I have been and am a peer reviewer for a number of international journals related to ML-ARD and environmental contamination. More details can be found at www.MDAG.com.

Prediction of Environmental Impacts at the Proposed Great Bear Project if Mined

The classic steps to environmental assessment are:

1) identify and quantify all potential contaminant sources including the rock walls of underground workings, waste-rock dumps, low-grade ore stockpiles, tailings, overburden, treatment plants, roads, and broken-rock foundations for buildings, including their rates of contaminant release, concentrations, and loadings (concentration multiplied by flow) for each of these sources;

2) identify and quantify subsurface, surface, and airborne pathways for contaminants to leave each of the on-site sources including velocities and loadings of all water pathways and all dust pathways; and

3) identify and quantify the expected physical, chemical, and biological impacts resulting from the on-site sources and their on-site/off-site pathways above.

On the chemical side, Step 1 above is often called "ML-ARD" or "geochemical source terms". If Step 1 is based on uncertain preliminary information and assumptions, which is currently the case for the Great Bear Project, then every source, pathway, impact, and outcome of the environmental impact assessment is also uncertain and assumed. To put it another way, impacts cannot be reliably estimated if the contaminants, their concentrations, and their loadings at their sources are not reliably known or predicted.

The 600-page federal-government ML-ARD Prediction Manual[1] from 2009, and required by Ontario Regulation 240/00 on ML-ARD, lays out a phase-by-phase approach to reliably defining each potential contaminant source and its contaminant release including rate, intensity, and severity. This often requires at least two to three years. Even then, for the Great Bear Project, another phase may be needed as explained in the federal Prediction Manual, but no one knows for sure until the initial phases are completed for the Great Bear Project.

[1] Price, W.A. 2009. Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials. Canadian MEND Report 1.20.1, Natural Resources Canada, dated December 2009.

It is important to note that some of this ML-ARD work for the Great Bear Project started last year (2023) and apparently more has started this year. Thus, I expect the phases of ML-ARD work and the reliable geochemical source terms to become available sometime in or after 2026 for the Great Bear Project. This applies to both Advanced Exploration and proposed mining. While preliminary information will be available before this time, it cannot be confirmed as reliable under the federal ML-ARD Prediction Manual.

Until the years of ML-ARD prediction work is done, a reliable plan for water treatment cannot be made for the Great Bear Project. Minewater-treatment plants are not off-the-shelf available at stores like Canadian Tire. This is because their treated effluent concentrations to the environment are very sensitive to the site-specific inflow rate of water and to the inflowing variations in aqueous concentrations of each element requiring treatment.

If upon mining, another "unexpected" yet predictable chemical element becomes a contaminant, then partially-treated toxic water would be discharged to the environment until a new treatment circuit could be added to the treatment plant. This would normally take at least months of time. After a new circuit is added, large overall changes can happen like the flow through the treatment plant ("residence time") could change and the concentrations of some other elements might not be lowered as much as predicted by initial treatment. Thus, environmental impacts of treated effluent can increase as "unexpected" but predictable contaminants arise.

For these reasons, concentrations and flows in water and air leaving the Great Bear site after treatment cannot be assumed in advance. This requires site-specific water-treatment tests, which have not been done for Great Bear and cannot be done until after the ML-ARD work is finished in a few years.

To cut short and bypass this issue, you may hear some people say something like, "We will continue with the impact assessment using this table of aqueous concentrations leaving the treatment plant." At this time, such a statement is uncertain, speculative, and based on assumptions. It would be an attempt to get through the impact-assessment process without reliable knowledge of (1) ML-ARD source terms and (2) the site-specific capability of the eventually-chosen treatment process. Also, this approach would ignore the fugitive contamination through water and air that inevitably escapes treatment and can cause environmental impacts.

It has been known for decades by many mining companies that ML-ARD work for contaminant predictions has to be started years before the final, reliable, expert-certified results are needed. This has been recognized for decades to avoid forcing environmental assessments using preliminary and initial information. If agencies choose to accept such preliminary information and assumptions, then they become participants in agreeing to or approving an impact assessment based on unverified and uncertified information. In the worst case, this can lead to environmental disasters. In the best case, this can lead to additional, apparently "unexpected" yet predictable cumulative effects about which Grassy Narrows First Nation is very concerned.

Prediction of Environmental Impacts at the Proposed Great Bear Project during Advanced Exploration

Please note that, further to my letter of March 27 to you, in some provinces no tonnage more than 10,000 tonnes is allowed during each five year period of advanced exploration. As a result, such a relatively large bulk sample of 60,000 tonnes at the Great Bear Project, with a gold value likely worth tens of millions of dollars, and spanning at least four years, can be considered a first phase of mining in some jurisdictions. This is not typical of advanced exploration elsewhere, where significant uncertainty normally remains about whether a project should continue. The Project Definition Document (December 2022) points out this is not unheard of in Ontario:

> "... such as the Timmins West Project (100,000 t), Sugar Zone Project (70,000 t) and Upper Beaver Project (60,000 t)".[2]

Advanced Exploration at the Great Bear Project is expected to remove up to 60,000 tonnes of ore as a bulk sample, requiring approximately four years. However, the potential for large and serious environmental impacts goes much farther than this, and includes the following.

- Around 1,000,000 tonnes of waste rock will be mined along with the bulk sample, of which at least some significant portion is expected to seriously contaminate infiltrating rainfall and snowmelt by ML-ARD for several years. The potential for severe environmental impacts by this waste rock continues because the worst rock would be excavated and placed back underground. When underground, the ML-ARD rock would eventually be submerged after an unspecified number of years. The rising underground water levels would rapidly flush years of accumulated contaminants off this rock. As a result, there could reasonably be far worse contaminant levels in the groundwater, that would eventually flow into the surrounding environment, than observed during active years of Advanced Exploration.
- At least ~400,000 tonnes of overburden (increased from ~200,000 tonnes in earlier documents) will be piled at the surface where it is intended to remain and even be used for reclamation. Based on percentages around Canada, there is a 50% probability that significant portions of the overburden will contaminate water with ML-ARD. However, to date overburden has been poorly characterized at the Great Bear Project and is assumed to be benign, where it will be spread around the site for reclamation.
- The proposed water treatment, for the contaminated water that does not escape into the environment during Advanced Exploration, is ambiguous and thus unreliable. This is understandable because of the missing ML-ARD input to design the treatment process reliably for all relevant contaminants. Currently proposed treatment includes aspects such as (1) pH adjustment, (2) flocculation which only affects suspended particles, (3) ultrafiltration that does not seem to match what is normally considered ultrafiltration, and (4) specialized ammonia treatment with no explanation why

[2] WSP E&I Canada Limited. 2022. Great Bear Advanced Exploration Project Project Definition Document. Report to the Great Bear Project, dated December 2022

nitrate and nitrite normally accompanying elevated ammonia are not included. Additionally, I understand that aqueous sulphate concentrations can increase the methylation of mercury and other elements like cadmium and arsenic, which is a major concern of Grassy Narrows First Nation. However, sulphate is not mentioned at all for Advanced Exploration at the Great Bear Project, despite the recognition that ML-ARD that releases sulphate is expected during Advanced Exploration.

- There are many more potential environmental impacts from Advanced Exploration that I am currently compiling for you at this time.

Because of the substantial potential for on-site and off-site environmental impacts by the proposed Advanced Exploration at the Great Bear Project, which includes surface water, groundwater, creeks and lakes, aquatic life including fish, and fugitive dust, a detailed impact assessment is warranted for the proposed Advanced Exploration. This current lapse of no planned impact assessment is environmentally risky and environmentally dangerous. This lapse could in the worst case result in very serious impacts to Grassy Narrows First Nation.

Summary

In summary, I understand Grassy Narrows First Nation's intention to make the impact-assessment process as comprehensive and rigorous as possible. However, this will not be possible for at least a few years. All estimated environmental impacts before that time will be preliminary and subject to major changes, because the final on-source contamination will not be reliably defined and quantified. The ML-ARD and geochemical source terms, which is the first step on which all subsequent steps of impact assessment rely, will not be known reliably for at least a few years for both proposed Advanced Exploration and proposed mining.

Sincerely,

Kevin A. Morin, Ph.D., P.Geo., L.Hydrogeo.

Dear MINES, IAAC, Kinross and Great Bear Resources:

RE: The Great Bear Gold Mine Project

I wrote to you on March 29 and April 15 to provide initial findings from Dr. Kevin Morin concerning metal leaching and acid rock drainage, water quality and hydrogeology with respect to the Great Bear Gold Project.

Please find enclosed:

- Dr. Morin's response to Kinross Gold's consultant, WSP. He concludes that he remains concerned about the many potential environmental impacts that are not recognized and not anticipated by Kinross Gold and about the many impacts that are recognized but poorly addressed and characterized. His concerns pertain to both the proposed advanced exploration and the proposed mining.

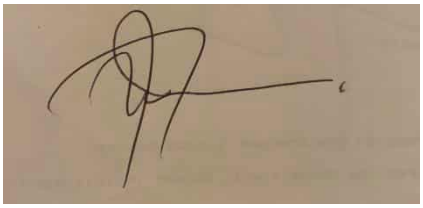
- Dr. Morin's report following his review of the technical documents provided to Grassy Narrows to date: Project Definition; Geochemical Characterization Workplan; Advanced Exploration Program Reclamation Strategy; Program Closure Plan (Draft for Indigenous Review); Hydrogeological Workplan; Surface

Water Quality Workplan; Fugitive Dust Best Management Practices Plan; PTTW Application for Dewatering; Draft Detailed Project Description; Water Treatment during Proposed Exploration and Proposed Mining.

Based on Dr. Morin's export reports, Grassy Narrows is extremely concerned that the project is moving ahead swiftly in the absence of required information and at great risk to the environment, the health, inherent, Treaty and Indigenous rights of Grassy Narrows.

I repeat Grassy Narrows' call to freeze the regulatory process work on this project until full credible information is available and the barriers to Grassy Narrows' meaningful involvement have been resolved. I also repeat Grassy Narrows' position that this project, including the extensive mining of valuable ore that the company is calling "bulk sampling", must be subjected to a rigorous environmental assessment.

Miigwetch,



Joseph B. Fobister, Lead Negotiator of Grassy Narrows Lands Protection Team

Grassy Narrows First Nation
c/o Cavalluzzo
474 Bathurst Street, Suite 300,
Toronto, Ontario M5T 2S6
Attn: Grassy Narrows Lands Protection Team

Dear Grassy Narrows Lands Protection Team,

RE: Great Bear Mining Project - Response to Kinross Gold on MDAG Initial Comments of March 27 2024

I have submitted to you two letters in the past about environmental concerns at the Great Bear Project, dated March 27 and April 11. These letters were based on some of my initial findings from some documents that were within my focus on metal leaching and acid rock drainage (ML-ARD), water quality, and hydrogeology. My review is now complete, including more detailed explanations for those earlier, initial comments as well as additional comments and concerns. My full review accompanies this letter of April 23.

Kinross Gold's consultant, WSP, replied to my first letter of March 27 on April 4. WSP sent a table with 18 issues, listed as "MSDAG [sic] Letter - Comments and Rationale" with a corresponding "GBR Response".

Please note that I did not include full "Rationales" with my initial letters because my detailed review was still in progress. Thus, it was not possible for WSP to provide satisfactory responses. My detailed "Rationales" were provided to you only today.

In any case, I explained that there was little reliable and professionally certified information on ML-ARD, water quality, and hydrogeology at this point for the Great Bear Project. Most Great Bear reports included labels like "preliminary", "draft", and "initial", which meant they were not complete, not certified as reliable, and subject to change one or more times in the future. In fact, some information and designs already changed substantially in 2023, as the accompanying review confirms.

Many of WSP's Responses reflected this. For example, the first WSP Response starts with:

> "The geochemical information presented in these reports represent initial draft documents for the Project, based on data collected in 2022 and early 2023 which was developed [sic] qualified professionals."

As I explained previously, my opinion is that preliminary, draft, and initial reports for the Great Bear Project that are not signed and certified by qualified professionals should not be reviewed. They are subject to change, and already some reports issued in 2023 contradicted others. I expect this to continue for at least a few years until final, reliable monitoring data and testwork are completed.

As a result, it is not worthwhile or meaningful to reply to WSP's Responses to my first letter. There are insufficient information and data at this time to debate and clarify many of my concerns and issues. There may or may not be sufficient information and data in future years. Only time will tell.

Therefore, based on the information available at this time for the Great Bear Project, I remain concerned about the many potential environmental impacts that are not recognized and not anticipated by Kinross Gold and about the many impacts that are recognized but poorly addressed and characterized. My concerns pertain to both the proposed advanced exploration and the proposed mining.

Sincerely,

Kevin A. Morin, Ph.D., P.Geo., L.Hydrogeo.

Report Summary

This MDAG review has focussed on the potential for contamination of water by metal leaching and acid rock drainage (ML-ARD) on, under, and around the Great Bear Project during proposed exploration and proposed mining.

It is important to note that some report titles for Great Bear contain the words "draft", "preliminary" or "initial", meaning newer drafts and revised final versions from Kinross Gold may or may not change from what has been reviewed here. Also, the first cover page for the Detailed Project Description of November 2023 says "draft" while the second WSP cover page does not. Thus, I have found that the reviewed documents for the Great Bear Project as a whole is a confusing mess of shifting, changing, contradicted, and assumed details, with none signed and certified by qualified professionals.

Also, the contents of some documents are password protected. This protected text and information cannot be extracted for detailed evaluation, quotation, review, and comment now or in the future. Thus, they preclude detailed reviews by Grassy Narrows First Nation, which is what Kinross Gold seeks.

Each section of this MDAG review looked in detail at a particular report on proposed exploration and/or proposed mining. The following paragraphs are the summaries taken from each section, and each section should be consulted for details and context.

Section 2 of this MDAG Review

For the password-protected Project Definition Document of December 2022, sufficient details and omissions are present for me to be very concerned about ML-ARD and water-quality degradation during and after the relatively large, at-least-four-years-long proposed Advanced Exploration that would essentially be a first phase of mining at Great Bear. These concerns carry over to the proposed mining.

Although this document is not marked as "draft" and is thus final, it contains many details contradicted by later documents as explained in later sections of this MDAG review. Thus, it is not possible to know exactly what is proposed for Advanced Exploration and, in turn, to know reliably how bad the environmental problems and impacts could be.

Section 3 of this MDAG Review

Problems detected in the January 2023 Geochemical Characterization Workplan include:

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross wants to proceed with

Advanced Exploration.

- All that is available now is 96 rock core analyses according to the September 2023 Reclamation Summary (see below), which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". In any case, the 96 samples were not collected and analyzed as required under the Ontario Mining Act (see next bullet). Thus, Kinross Gold and its consultants, WSP, are guessing how bad the contamination will be, but admit that some of it will be bad, and are likely years away from completing the ML-ARD work required under Regulation 240/00 of the Ontario Mining Act (Mine Development and Closure under Part VII Of the Act).

- The stated approach and methodology used for Advanced Exploration is "based on the requirements" of two British Columbia documents from 1997-1998 (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997). In reality, the Ontario Mining Act says the approach and methodology must be based on the much more detailed 2009 federal Prediction Manual, not just as "guidance" as Great Bear has done. Thus, the work for Advanced Exploration to date does not meet the Ontario Mining Act through Regulation 240/00 and does not meet the 2009 federal ML-ARD Prediction Manual (Price, 2009).

- Even if this Geochemical Characterization Workplan was applicable and consistent with the 2009 federal ML-ARD Prediction Manual, such work requires at least 2-3 years to obtain all required information and interpretations. Therefore, perhaps in 2025 or some year after, there might be sufficient ML-ARD for Advanced Exploration, but not any time soon.

Section 4 of this MDAG Review

Concerns on the Reclamation Strategy from September 2023 include the following.

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross Gold wants to proceed with Advanced Exploration.

- All that is available now is 96 core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". Also, 30 samples of overburden, which is intended to be left on surface and used for reclamation, were collected yet the results are not reported although there is ~50% probability that the overburden will release ML-ARD and thus be toxic. Kinross Gold and WSP are guessing how bad the contamination will be, but admit that some of it will be bad. They are likely years away from completing the ML-ARD work required under the Ontario Mining Act and Regulation 240/00, because the work for Great Bear was not initially consistent with Regulation 240/00. In part, this is because the 2009 federal ML-ARD Prediction Manual (Price, 2009) was not recognized or followed as required. Even the

definitions of ML-ARD acronyms used for the Great Bear Project are not correct according to the federal Manual, which is additional evidence the Prediction Manual is not being followed.

- The bad ML-ARD rock appears to be associated with "rapid acid generation" according to the Program Closure Plan (reviewed in the next section below). This is an incorrect explanation of the phenomenon, but still shows that the bad water quality will start coming out of the disturbed rock, including the underground mine walls, very quickly after initial disturbance. Informally, this is called "lag time" to ML-ARD, but most of the ML-ARD work has not yet been done to quantitatively estimate the lag time beyond "rapid". This contaminating rock will be stored on surface and possibly only later, likely after the lag time, some might be taken underground. When this rock contacts water underground as the workings partially flood and submerge, it will quickly release more contamination. This means the underground water flowing into the surrounding groundwater system, and the surface overflow if any, would have to be monitored and likely be treated for many years or in perpetuity after Advanced Exploration.

Section 5 of this MDAG Review

For the password-protected Program Closure Plan, Draft for Indigenous Review from November 2023, the following concerns were noted.

- In November 2023, the volume of overburden has approximately doubled from previous documents without an explanation. Because overburden generally has a 50% probability of releasing ML-ARD and contaminating water, overburden represents a major but unexamined threat to water quality on, around, and beneath the Great Bear exploration site.

- "Preliminary" criteria are provided for separating "PAG" and "NPAG" rock and for "NML" rock. However, these acronyms are not used in an accurate manner that is consistent with the 2009 federal Prediction Manual (Price, 2009) required by Regulation 240/00. The preliminary criteria are not rational based on ML-ARD science unless justified with detailed and intensive site-specific studies, which have not yet been completed and professionally certified for the Great Bear Project.

- The potential for ML-ARD after closure is presented all the way to detailed predictions of aqueous concentrations in mg/L for on-site water and effluent to the environment, but only after closure and not during operations when the water quality would be reasonably worse. However, these predictions are not explained in any detail, are not justified, appear anomalous, and are not certified by a qualified professional. Some predictions are actually pre-exploration baseline that are erroneously assumed to be re-established immediately at closure. Furthermore, these predictions are missing more than a dozen potential contaminants.

- The "PAG" rock, which would likely create the highest contaminant concentrations, is not included

in this Program Closure Plan, presumably because this "PAG" rock will be backfilled underground. However, when placed underground, this "PAG" rock will likely continue to release severe ML-ARD until submerged, at which point a relatively huge amount of accumulated contamination would be released into the underground water. After the mine is refilled to equilibrium, and the minewater begins flowing into the surrounding groundwater system and through the more than 500 km of permeable drillholes to the environment, it will contaminate large surrounding areas. This major risk to water quality and the environment is not even mentioned in this Closure Plan, which is a major omission.

- The backfilling of "PAG" rock at closure is the largest individual cost item for closure totalling around $10 million. However, this reflects the currently minimum volume based on preliminary, unreliable information. In the worst case, which was assumed in the Great Bear Project Definition and still not disproven here, total closure costs could exceed $20 million.

Section 6 of this MDAG Review

In the Hydrogeological Workplan from December 2022, there is a major omission that would preclude a reliable and comprehensive assessment of current baseline hydrogeologic conditions and of future impacts from proposed mining. The groundwater monitoring network does not extend far enough to the west and northwest, beyond the proposed western portion of the Tailings Management Facility.

Section 7 of this MDAG Review

In the Surface Water Quality Workplan from December 2022, there are insufficient information and details to determine if appropriate work is planned and conducted. This is because important details are listed only as "including". For example, major potential contaminants like manganese and thallium are not specifically listed, but perhaps they are implicitly included? There is no way to know.

Section 8 of this MDAG Review

Based on the final-draft Fugitive Dust Best Management Practices Plan of September 2023 for Advanced Exploration, this work is unacceptable because it grossly underestimates the potential impacts from ML-ARD geochemical contamination of soil, vegetation, water, and biota by dust. This work assumes the on-site sources of dust "would be similar in concentration to the background rock". This is wrong and ignores the ongoing ML-ARD assessment of ore, rock, and overburden.

Section 9 of this MDAG Review

In the PTTW (Permit To Take Water) Application for Dewatering, Final Draft, and its several

important appendices from October 2023, there are alarming errors and ambiguities that should preclude approval of PTTW. These should also trigger a detailed impact assessment, which this PTTW report conversely says is not needed for Advanced Exploration at Great Bear.

In the introduction to the main PTTW report, the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning because the actual total water withdrawal from the local groundwater/surface-water balance would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these flows are unrealistically low as explained here.

The errors begin with groundwater modelling that is based on long-term "steady state conditions" after the mine is "fully developed" and dewatered, and not on the correct, higher-inflow "transient conditions". Thus, inflow, pumping, and dewatering are significantly underestimated by the groundwater model and the PTTW Application. Additionally, there are problems with unrealistically low estimated effects on partial dewatering of Dixie Creek and other creeks and rivers. For example, simulated groundwater levels are around 9 m higher than measured around the mine and Dixie Creek, which artificially and incorrectly prevent additional dewatering of Dixie Creek.

Groundwater levels are shown to be drawn down during dewatering to a maximum of only 36 m even though the dewatered workings will be 600 m deep. This reflects (1) nearly fully dewatering of the shallow overburden and (2) the lack of admission on the likely huge drawdown and much larger "Zone of Influence" in the rock beneath the overburden.

Baseflows into Dixie Creek and other waterbodies can be critical to aquatic, benthic, and terrestrial ecosystems because of groundwater's typically different water quality and temperature compared to water already flowing at the surface. This becomes more critical during droughts when baseflow may be the main source of surface flows. The PTTW Application ignores the fact that more than 34 to 55% of existing baseflow would be lost during Advanced Exploration. It instead points out that the loss to groundwater would be only 2.4% and less of total flow depending on the chosen surface-flow statistic.

Overburden is routinely ignored in this PTTW document and its appendices, despite the proposed hundreds of thousands of tonnes of overburden likely having at least some ML-ARD potential and capacity to degrade water quality. In fact, some underground dewatering would be sprayed on the overburden for dust suppression, which in turn could lead to contaminated runoff across and off the site.

Section 10 of this MDAG Review

In the perhaps-draft Detailed Project Description of November 2023, the first cover page by Kinross says this document is "draft", but the second cover page by the authors, WSP, does not say "draft" so perhaps this is or is not the final document. If so, it has not been signed by qualified professionals and thus should be rejected.

In any case, there are so many problems, misleading statements, errors and omission concerning ML-ARD, water quality, and environmental impacts that they cannot all be summarized well here. These problems include the following.

- There is a false statement that there will be no sources of mercury from the ore processing when in fact the tailings and concentrate from the process will contain mercury. The processing could even cause mercury and other elements to leach more quickly and become more mobile.

- Contrary to the impression given by this Detailed Project Description, cyanide destruction is not perfect and can simply mask the cyanide temporarily in the environment, but the important testwork to determine this has not yet been done for the Great Bear Project.

- Significant impacts on water quality can arise from seemingly benign proposed activities like paste backfill of tailings into the underground mine and dewatered filter-cake tailings. However, the potentials for serious impacts are not recognized or not even mentioned in this perhaps-draft Great Bear document that can supposedly be used to determine what impacts could occur.

- Storm events and equipment upsets can lead to relatively large variations and unexpected impacts, day-to-day or even hour-to-hour, during proposed exploration and proposed mining. Instead, these Great Bear documents use averages like monthly which incorrectly assume flows will be the same every day of a month which is far from reality. Environmental impacts and spills can also be caused by large variations, as well as longer-term averages, so the environmental risks of proposed exploration and proposed mining at Great Bear remain mostly unknown and not identified.

- Nonsense pseudo-scientific statements are used, like the aggregate required to build the project would be “nonreactive mine rock and overburden” which does not exist. This clearly shows that experienced and qualified professionals were not included in the writing of this perhaps-draft Detailed Project Description. If there is a true commitment to “nonreactive mine rock and overburden” which does not exist, then the Great Bear Project stops now.

- There is a lack of ML-ARD assessments for some site components like aggregate.

- There is a prevalent but likely false belief that “NPAG”rock will have little to no impacts on ML-ARD, water quality, and the environment. However, this has not been proven for the Great Bear Project and is likely wrong based on other minesites around Canada. “NPAG” rock can actually generate more acid than “PAG” rock and could still release seriously contaminated levels of many metals and other elements at near-neutral pH.

- The financial assurance to ensure proper and fully paid closure of the proposed Great Bear Project is grossly underestimated based on existing information. Furthermore, the financial assurance should also include contingencies for costs of early or premature closure, but it does not.

- There are likely devastating, expensive, and unrecognized ML-ARD consequences on water quality from the proposed relocation of "PAG" rock into the underground workings after operation.

- The ongoing, unproven, and likely wrong, belief continues that overburden would be environmentally benign, can be used across the site for reclamation, and can be sprayed with water to control dusting when it could instead create contaminating water around, below, and beyond the Great Bear site.

- There are unfounded beliefs that dewatering during exploration and mining would have minimal effects on the local and regional water balance, and would not significantly dewater surface creeks and lakes including their environmentally important baseflow. These false beliefs are based on flawed groundwater modelling for the Great Bear Project explained earlier in this MDAG review.

- There is a false belief that dust blown off the site during proposed exploration and proposed mining and into the surrounding environment, vegetation, soil, water, and aquatic ecosystems is benign at "background" levels.

- A false belief is stated that only elevated and toxic ammonia, and no other contaminating nitrogen species from explosives that consistently accompany the ammonia, will appear in mine water during proposed exploration and proposed mining.

- There is an unsupported and likely substantially underestimated statement that the mine walls in the pits and underground workings "may potentially contribute minor quantities of metals to the mine water" instead of the more typical significant quantities of metals seen at many other minesites around Canada. This is taken as far as the likely ludicrous statement that there would be "Potential for creation of fish habitat in new pit lakes, expected to be re-connected [sic] to the Dixie Creek system".

- There is no recognition of the implications, costs, and impacts of storing months of contaminated mine water on the site should one or more "unexpected" yet currently predictable inorganic contaminants and ML-ARD occur on the site water during and after proposed exploration or proposed mining.

Section 11 of this MDAG Review

In summary for water treatment, Great Bear documents invoke water treatment as the major process that would prevent or minimize environmental impacts of proposed exploration and proposed mining. This is not literally true, because there will be fugitive contaminated water and contaminated dust leaving the site, but this fugitive contamination is ignored or not recognized in many reviewed Great Bear documents.

In any case, water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts, and thus requires intensive study and characterization.

However, at this time, water treatment for proposed exploration and proposed mining is ambiguous and contradictory among the documents. This should be expected because the input flows and input contaminant concentrations (ML-ARD) will not be known reliably for at least a few years. Nevertheless, there are serious concerns about water treatment now including the following.

- Kinross Gold does not expect to treat site water to non-toxic levels. Instead, treatment would only be down to still-toxic levels based on the Metal and Diamond Mine Effluent Regulations (MDMER). Thus, Kinross Gold intends to rely on significant dilution of its contaminated effluent within a "mixing zone" in the Chukuni River. Such a mixing zone would include zones of significant toxicity and would require formal authorization from Fisheries and Oceans Canada. In any case, this discharge of effluent would add to cumulative effects, which is a particular concern of Grassy Narrows First Nation.

- Expensive and intensive treatment for ammonia, derived from blasting residues, is proposed. However, toxic levels of nitrate and nitrite, that always accompany the ammonia and which can cause eutrophication and other impacts in the Chukuni River and Dixie Creek, are completely ignored.

- Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

- Ultrafiltration may substantially reduce effluent concentrations of elements not fully dissolved, mixing-zone size, and cumulative effects. However, there are no details on this ultrafiltration in the reviewed Great Bear documents.

- Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge", which can reach "hazardous" and "special" waste levels in some jurisdictions. Thus, treatment sludge requires the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and sediments including soils and benthic ecosystems. All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge that will remain and be managed somewhere in perpetuity.

1. Introduction

Metal leaching (ML) and acid rock drainage (ARD) are often water-chemistry and water-quality issues for minesites (e.g., Morin and Hutt, 1997 and 2001). As a result, the accurate prediction and control of ML-ARD at mining projects and proposed minesites in Ontario are high priorities of the provincial and federal governments.

This is explained in Part 7 (*Metal Leaching and Acid Rock Drainage Requirements*) of Ontario Regulation 240/00 (*Advanced Exploration, Mine Development and Closure under Part VII of the Act*), and in the federal ML-ARD Prediction Manual (Price, 2009). Section 57(1) of Regulation 240/00 states,

> "A program shall be undertaken to sample all materials remaining on the site that have been excavated, exposed or otherwise disturbed by mining activities, including but not limited to,
>
> (a) drill core;
> (b) metallurgical samples;
> (c) pit walls;
> (d) existing waste rock, ore, concentrate and *overburden* [MDAG emphasis] piles;
> (e) construction rock; and
> (f) tailings."

For detailed guidance, Ontario Regulation 240/00 states,

> "The sampling program shall be conducted by a person who is qualified in Ontario as a professional geoscientist, professional agrologist or professional engineer in accordance with a report prepared by William A. Price on behalf of the Mine Environment Neutral Drainage (MEND) program, entitled 'Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials', MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..." [Price, 2009]

ARD is caused by oxidation of sulphide minerals, which are found at the Great Bear Project, particularly iron-bearing sulphides like pyrite and pyrrhotite. Whether sulphide minerals are present or not, weathering can still lead to accelerated metal leaching (ML). For example, the simple dissolution of near-neutral or alkaline carbonate minerals can release metals like manganese and zinc into the water. Thus, ARD is a subset of the more generic ML.

In practice, ML is not limited to true metals in the Periodic Table, but to all elements that could become potential environmental contaminants. For example, sulphate and nitrate are regularly included in ML assessments. Sulphate can reportedly increase the methylation of mercury and other elements like cadmium and arsenic.

Therefore, ML-ARD is an acronym representing the full spectrum of inorganic water chemistry and quality on, beneath, and around a minesite. Put simply, ML-ARD potential is synonymous with the potential for inorganic water contamination and the degradation of on-site water quality.

Kinross Gold Corporation (Kinross Gold) proposes Advanced Exploration and later mining at its Great Bear Gold Mining Project in the Red Lake mining district of Ontario, approximately 25 km southeast of the Town of Red Lake. The Great Bear Project is located in the Interim Area of Interest for Mining of Asubpeeschoseewagong Netum Anishinabek (ANA), which Kinross documents also name as Grassy Narrows First Nation (GNFN). The Great Bear Project is also in an area where Grassy Narrows First Nation people use the land and water to practice their Indigenous way of life. It is located upstream of the English River which flows directly to the Grassy Narrows village site and Grassy Narrows' most important fishing grounds.

Through Cavalluzzo LLP, the Grassy Narrows Lands Protection Team has asked me, Dr. Kevin Morin of the Minesite Drainage Assessment Group (MDAG), to review and comment on the proposed exploration and proposed mining. This MDAG review focuses on predicted surficial and subsurface ML-ARD and water quality on and around the Great Bear Project.

My qualifications for making the comments in this review document include the following. I have been assessing water contamination at minesites by metal leaching and acid rock drainage (ML-ARD) for 46 years. I have done this at several hundreds of exploration, operating, and closed mining-related sites on all continents except Antarctica, from north of the Arctic Circle to south of the Tropic of Capricorn, in biogeoclimatic zones ranging from virtually no annual precipitation up to a rare daily rainfall of one meter. I earned my Doctor of Philosophy degree in contaminant hydrogeology from the University of Waterloo, where my supervisor was the renowned Dr. John Cherry along with a thesis committee including Drs. Emil Frind (a well-known groundwater modeller) and Eric Reardon (a well-known geochemist). To date, I have authored or co-authored 99 published papers and presentations, five books, and 80 online case studies. I have been and am a peer reviewer for a number of international journals related to ML-ARD and environmental contamination. More details can be found at www.MDAG.com.

The Kinross documents reviewed in the following sections are listed below. Again, the main focus is on the potential for contamination of water by ML-ARD on, under, and around the Great Bear Project during proposed exploration and proposed mining.

- Project Definition Document (December 2022)
- Updated Site Plan
- PTTW Application for Dewatering, final draft (October 2023)
- Fugitive Dust Best Management Practices Plan, final draft (September 2023)
- Reclamation Strategy (September 5, 2023)
- Program Closure Plan, Draft For Indigenous Review (November 2023)
- Surface Water Quality Workplan (December 21, 2022)
- Hydrogeological Workplan (December 21, 2022)
- Geochemical Characterization Workplan (January 9, 2023)
- Preliminary Impact Assessment Methodology, draft (May 31, 2023)
- Preliminary Listing of Potential Valued Components for the Great Bear Project (May 31, 2023)
- Initial Project Description (June 1, 2023)
- Detailed Project Description (November 2023)

- PowerPoint Presentation by Kinross to ANA (November 10, 2023)
- ANA IPCA Map

It is important to note that some report titles above contain the words “draft”, “preliminary” or “initial”, meaning newer drafts and revised final versions from Kinross Gold may or may not change from what has been reviewed here.

Also, the contents of some documents above are password protected. This protected text and information cannot be extracted for detailed evaluation, quotation, review, and comment now or in the future. This precludes the detailed review by Grassy Narrows First Nation that Kinross Gold seeks. I strongly recommend that unlocked versions of all Kinross documents be obtained and kept by Cavalluzzo LLP and the Grassy Narrows First Nation for future reference and usage.

2. Project Definition Document (December 2022)

The Great Bear Resources Great Bear Advanced Exploration Project Project Definition Document, dated December 2022 by WSP E&I Canada Limited (WSP), is a password-protected document from which its content cannot be extracted or copied for detailed evaluation and reinterpretation.

In the Preface of this document, WSP states,

> "The Project as described in this document is subject to change as engineering progresses, in response to feedback from government agencies, Indigenous communities and stakeholders, as well as constraints not currently known, that are identified by ongoing environmental baseline and engineering works, and Indigenous consultation and engagement."

No new or updated Project Definition could be located and thus this version from December 2022 is reviewed here from the perspective of ML-ARD and potential water contamination.

Section 1.3 explains the objective of the proposed Advanced Exploration and its key activities:

> "The objective of this Project is to obtain additional information on the known mineralized zones (LP Fault, Limb Zone and Hinge Zone; Figure 1-3) through underground drilling, and to extract a bulk ore sample of up to 60,000 tonne (t) by underground mining methods. Extraction of a bulk sample allows the testing of representative areas of the mineralization off site, in order to gain a better understanding of the geology of the mineralized zones including, grade, structural controls on the mineralization, continuity, mining dilution, optical sorter performance and metallurgical recoveries. This information will support the assessment and development of a viable commercial production scenario.
>
> "The Project will also support future engineering designs by improving knowledge of key factors (ground conditions, water inflows, costs, labor, etc.). It will also improve the knowledge base to increase the confidence in environmental predictions associated with the proposed underground mine and to a lesser extent open pit mine.
>
> "Key Project activities are provided below:
> - Establish portal(s) and decline(s) to provide access underground in order to establish required underground workings
> - Develop drill platforms off the decline to facilitate efficient underground drilling of the known mineralized zones at depth
> - Extract up to 60,000 t of ore (bulk) sample from test stopes and drifts in the mineralized zones
> - Transport the ore to surface along the decline(s) by truck for crushing, sorting and sampling; samples will transported off site by highway truck for test processing
> - Mine rock that must be removed from the underground workings in order to provide access to the ore will be brought to surface by truck and will be stored in stockpile(s) unless appropriate for use as a construction material on site
> - Additional activities on surface and underground, such as environmental management."

These quotations raise several concerns as explained next.

Section 1.4 "Consultation to Date" with First Nations mentions Wabauskang First Nation (WFN) and Lac Seul First Nation (LSFN) in several places including an Exploration Accommodation Agreement. In contrast, Grassy Narrows First Nation (GNFN) in mentioned only twice, including where the Ontario Ministry of Mines instructed Kinross Gold to include GNFN in notifications of significant updates on exploration works. Later, Section 7.4.1 adds,

> "On September 29, 2022, the Company communicated its interest in an introductory meeting to GNFN, who respectfully declined the offer."

Section 1.5 on "Involvement of Federal Agencies" in this Project Definition starts by saying "Not currently applicable". Then it clarifies:

> "No Federal government departments or agencies are expected to grant Federal land or providing financial support to the project (include indirect funding support, such as for infrastructure and training). There is the potential that Federal departments may be required to provide environmental approvals or authorizations (see Section 7.3.1)."

Federal agencies like Fisheries and Oceans Canada will very likely be involved in authorizations as the Great Bear Project intends to discharge toxic water including from its advanced-exploration treatment plant into fish-bearing waters and fish habitat as "mixing zones" requiring authorizations. This is discussed further in Section 11 of this MDAG review.

Section 5.1.1 on Existing / Previous Development, Operations and Facilities says:

> "The first exploration work documented by Geology Ontario on the Property dates from 1944. Prior to acquisition by Great Bear Resources Ltd. in 2017, 176 diamond drillholes had been completed totalling 32,602.8 metres (m).... As of October 2022, there has been over 500,000 m of diamond drilling on the Property."

For understanding how groundwater might move during and after proposed Advanced Exploration, these hundreds of drillholes more than 500 km in total length create very permeable pathways for subsurface water to travel long distances quickly, in violation of normal hydrogeologic principles like hydraulic gradients and hydraulic conductivities. This is not acknowledged in other Great Bear documents, as explained in sections of this MDAG review such as Sections 6 and 9.2.

Section 5.1.3 on Geology and Mineralogy says:

> "The Property lies locally within a regional northwest-southeast trending belt of metavolcanic and metasedimentary rocks, bound by intrusive batholiths (see Figure 5-1). The Project is targeting gold mineralization, currently identified within three mineralized zones (see Figure 1-3):
>
> - LP Fault Zone, disseminated gold within high strain
> - Limb Zone (previously known as the Dixie Limb), silica-sulphide replacement
> - Hinge Zone, quartz veining."

The 2009 federal ML-ARD Prediction Manual (Price, 2009) shows that the ML-ARD and potential contamination from each of these zones requires separate ML-ARD evaluations. However, the proposed underground drifts are from a limited area of the ore zones, contrary to a statement that Advanced Exploration is needed to check "the continuity of underground access gold deposits" (see below).

Section 5.1.4 on Geochemical and Geotechnical Considerations states:

> "Geochemical characterization work has been initiated in order to support potential future development, including meeting the requirements of the Mine Rehabilitation Code for a future Advanced Exploration Closure Plan. Ongoing work include static testing (acid base accounting, short-term leaching), mineralogy and metal content. Humidity cells and rain barrel tests are also proposed. The conservative [worst-case] assumption pending results of the comprehensive testing program, is that ore and mine rock is potentially acid generating. This assumption will be amended on receipt of the pending test results and further assessment."

This worst-case assumption (incorrectly stated as "potentially acid generating" in comparison to the federal ML-ARD Prediction Manual) that all ore and mine rock will release ML-ARD could still be the case now, despite recent statements to the contrary (see the sections below in this review). This is because important ML-ARD work has not been completed and then certified by a qualified professional.

Section 5.1.4 also describes the overburden at the Project, which requires ML-ARD assessment equal to those of waste rock and ore according to the federal ML-ARD Prediction Manual and Ontario Regulation 240/00.

> "At the northwest portion of the Property, surficial soils are glaciofluvial in origin, consisting of sands and gravels. In the central portion of the Property, the surficial soils are described as deep-water deposits comprised of laminated to varved clay, silt and fine sand (Natural Resources Canada, 1996). Based on current exploration drilling information, overburden thickness at the Property is expected to range between 0 to 40 m. There are limited bedrock exposures within the Project area. Overburden encountered to date is a mix of sand, gravel and clay; however zones of soft sensitive clays may be encountered. An extensive geotechnical drilling program is currently underway on the Property to further investigate these and other aspects."

Section 5.1.5 on Proposed Mining Activities contains many important details such as:

> "There is no production mining proposed for the site." [MDAG Note: This appears to be a play on words because significant mining for several years is in fact proposed and Section 5.1.5 is specifically entitled "Proposed Mining Activities"; see my comments below on Section 5.1.8]. This Project includes use of underground mining methods to obtain a bulk sample of up to 60,000 t. The work is to be initiated in 2023, pending consultation, regulatory approvals and a corporate decision to proceed."

Kinross Gold further explained details of the proposed Advanced Exploration in Section 5.1.5:

> "The goal of the advanced exploration program (and ongoing exploration drilling from surface), is to collect additional information to support a decision on whether to proceed to develop a mine and to support engineering design. The advanced exploration bulk ore sample will be trucked off site over the existing Provincial road network to an existing mineral testing facility. No onsite processing is proposed.
>
> "GBR proposes to collar one or two portals from surface (approximately 6 m by 6 m) and to develop associated decline ramp(s) of approximately the same dimension. Secondary

egress and ventilation may be provided through a raise. The ramp is projected to extend to a vertical depth of approximately 600 m below surface and length of approximately 9,000 m during the Project. A preliminary long-section and plan view of the advanced exploration underground workings showing the preferred portal and raise location is provided in Figure 5-2 and Figure 5-3. The ramp is designed to provide access to the investigation areas, promote efficient truck haulage and reduce ventilation losses. Personnel will access the underground workings by means of the ramp. A shaft is not proposed for the Project.

"A bulk sample will be extracted from underground workings developed from the ramp(s) using conventional drilling and blasting using explosives, from several locations within the deposit. Blasting is proposed to use prepackaged and bulk explosive products....

"The objective of this Project is to obtain additional information on the known mineralized zones (LP Fault, Limb Zone and Hinge Zone; see Figure 1-3) through underground drilling and extraction of a bulk ore sample. Extraction of bulk sample allows testing of representative areas of the mineralization in order to gain a better understanding of the geology of the mineralized zones including, grade, structural controls on the mineralization, continuity, mining dilution, optical sorter performance, crushing and grinding properties and metallurgical recoveries to support development of a viable commercial production scenario.

"Industry-specific factors that were considered by GBR when establishing the size of the bulk sample include as follows:

- The proposed bulk sample is approximately 1% of the currently defined mineralized envelope and is consistent with other Ontario advanced exploration projects, such as the Timmins West Project (100,000 t), Sugar Zone Project (70,000 t) and Upper Beaver Project (60,000 t)
- Representative bulk samples extracted using realistic mining methods that help to prove the continuity of underground access gold deposits are very important to potential financiers
- National Instrument 43-101 resource definition and economic modeling standards are becoming more stringent to satisfy stricter due diligence standards imposed by industry and the investment community, often requiring bulk samples to validate and refine resource models prior to production decisions."

The problem with these details is that the three reasons given by Kinross Gold do not justify the 60,000 t bulk sample nor the proposed locations for the removal of the bulk sample. For example, the figure shows that most of the bulk sample will be taken from two laterally-limited areas. As a result, most of the ore from northwest to southeast will not be sampled. This is not consistent with proving "the continuity of underground access gold deposits".

Section 5.1.8 on Project Duration and Rate of Mining shows that Underground Development will take place across more than four years "on a continuous (24-hour) basis" and the Bulk Sample will be collected across roughly 2.5 years. These details plus the two 6x6 m portals show this is not typical Advanced Exploration to determine if future mining might be justified, but this is the first phase of mining.

Section 5.3.8 Buildings and Large Facilities includes Table 5.2 "Primary Buildings and Facilities on Surface". "Mine Rock Stockpiles (2)" has an approximate scale of 1,000,000 t, although it is not clear on whether this is maximum capacity or expected capacity. This is only clarified later under Section 5.4.3 (see below) which is the only description of the volume of disturbed waste rock (1,000,000 t) left on site simply to obtain 60,000 t of ore (a ratio of 17:1). This implies a large percentage of waste rock will be mined during Advanced Exploration, which further supports the view that Advanced Exploration would be the first phase of mining.

Remarkably, the various ponds listed in Table 5.2 are only described as lateral areas and do not provide depths and volumes, precluding a discussion of mass balances and spills due to extreme weather events and failures of the treatment plant. Also, the total catchment of this proposed exploration site is not provided despite all its runoff and infiltration requiring routine monitoring and treatment as needed. These are serious omissions. These omissions continue in the perhaps-draft Detailed Project Description, reviewed in Section 10 below.

Despite 60,000 t of ore being mentioned many times in this Project Definition, Section 5.4.3 "Stockpiles" is the only section of this Project Definition that mentions the substantially greater amount of waste rock with ML-ARD potential:

> "It is estimated that a total quantity of approximately 1,000,000 t of mine rock will be generated and stockpiled during the Project."

Additionally:

> "A stockpile of up to 100,000 m^3 [of overburden] is proposed", which likely means about an additional 200,000 t of disturbed overburden.

Notably, less than a year later, documents (see the later sections of this MDAG review below) have increased the overburden to ~400,000 t with no clear explanation for it.

Overburden stockpiles at minesites around Canada have released significant ML-ARD, which is why they are specifically mentioned and referenced through the Ontario Mining Act, but this Project Definition fails to recognize this. Later Kinross Gold documents fail to show the overburden stockpile and fail to show its runoff reporting to ML-ARD treatment (e.g., the undated "AEX Site Plan - Updated.pdf" on which overburden is called "topsoil"). For example, "Memo - Reclamation Strategy - Sept 5 2023.pdf" says,

> "Runoff from the overburden stockpiles (will be monitored and treated to manage suspended solids as required and discharged)".

The undated "AEX Site Plan - Updated.pdf" does not show this. This is one of many glaring contradictions and errors among the Great Bear documents reviewed here.

The understanding of groundwater at this Project is incomplete or contradictory. Section 6.25. Says:

> "The bedrock is generally tight with some potential for limited groundwater flow in the upper fractured bedrock and a few deep structures."

However, a figure in Section 5.5.2 shows groundwater as the only source of inflowing water to the underground workings. Thus, Kinross is saying groundwater inflow is "limited" but also is the only source of this water that has to be actively pumped out of the mine. This escalates to serious errors in groundwater modelling explained in Section 9.2 below that incorrectly predicts relatively low groundwater inflow and relatively little dewatering of surface creeks and lakes.

Section 6.2.6 Air Emission Information has an important omission concerning ML-ARD, environmental impacts, and cumulative effects. This section simply says,

> "A meteorological station has been established on the site, and baseline air quality and sound data is being collected. Based on a review of current Project, air emissions are anticipated to be limited and no offsite impacts are predicted. A management plan will be established to mitigated dust from materials movement and traffic on gravel roads."

However, hundreds of thousands of tonnes of blasted waste rock plus disturbed overburden will remain on site in piles up to 30 m high, likely in perpetuity after Advanced Exploration. This contaminated, blasted, and disturbed materials can release ML-ARD contaminated dust that can be carried into the surrounding environment where it can affect and degrade water quality, soil quality, vegetation, microbes, fish, and animals. As explained in Section 8 of this MDAG review, this invalidates the fugitive dust study for the Great Bear Project.

In summary of this password-protected Project Definition Document of December 2022, sufficient details and omissions are present to be very concerned about ML-ARD and water-quality degradation during and after the relatively large, at-least-four-years-long proposed Advanced Exploration that would be essentially a first phase of mining at Great Bear. These concerns carry over to the proposed mining. Although this document is not marked as "draft" and is thus final, it contains many details contradicted by later documents as explained in later sections of this MDAG review. Thus, it is not possible to know exactly what is proposed for Advanced Exploration and thus to know reliably how bad the environmental problems and impacts could be.

3. Geochemical Characterization Workplan (January 9, 2023)

This very short, three-page summary of ML-ARD "geochemical characterization", apparently issued in January 2023 by WSP, does not provide much information to review and comment on since it is only a "Workplan". However, later documents show this Workplan was not followed.

Under "Purpose of the 2023 Program", it says:

> "Samples that have been or will be tested as part of the geochemistry program include drill core (representing mine rock), overburden, and synthetic tailings generated from metallurgical test programs conducted in the laboratory. Related water quality modelling will be undertaken in 2023, focusing on the proposed Advanced Exploration (AEX) phase. Additional water quality modelling, representing the overall Project, will be undertaken at a later date."

As explained below, this Workplan is not sufficiently thorough and complete under the 2009 federal ML-ARD Prediction Manual (Price, 2009) to justify water-quality modelling and its conclusions. In any case, it is now April 2024 and no verified modelling results from 2023 have been found.

Under "Mine Rock Static Testing", this Workplan states,

> "A mine rock characterization program was initiated in 2022. A total of approximately 300 samples of drill core were collected for this purpose as part of field work in 2022. Drill core samples were obtained from a variety of locations and depths around the deposit, including rock in the vicinity of the proposed open pit and underground developments, along with the proposed AEX volume. Samples of all major rock types were collected. The purpose of this work is to evaluate the ML/ARD potential of the rock and help determine how mine rock may need to be managed.... Testwork is underway and results will be available in the first quarter (Q1) of 2023."

However, nine months later in September 2023, the Reclamation Strategy (see the next section of this MDAG review) mentions only 96 samples that are only "proximal" and thus not necessarily representative of rock to be removed for Advanced Exploration or proposed mining. Perhaps the other 200 samples are not relevant for Advanced Exploration and proposed mining, but then because they are "proximal" it is possible that the 96 samples are not relevant either.

Under "Mine Rock Static Testing", it says

> "All samples will be tested for Acid Base Accounting (ABA) parameters (that includes paste pH, sulphur content and speciation, and Neutralization Potential content and form) and elemental content analysis (aqua regia digestion and ICP analysis). Some of the samples will be subjected to more detailed static tests including the Shake Flask Extraction (SFE) test, Net Acid Generation (NAG) test, and Rietveld X-Ray Diffraction. Testwork is underway and results will be available in the first quarter (Q1) of 2023."

This is insufficient detail to ensure the correct tests are being done. In fact, "aqua regia" is a partial digestion that detects only part of the heavy metals and other elements in a sample, and thus is not acceptable for most ML-ARD work including comparisons to total crustal abundances.

Also, the September 2023 Reclamation Strategy (see the next section) mentions the results of 96 core samples, without stating which methods were used and what the analytical results were. All this information "will be available in the first quarter (Q1) of 2023", but more than a year later the information is not available as qualified-professional-certified results and interpretations.

Under "Mine Rock Kinetic Testing Programs", it says:

> "Kinetic tests are used to assess how a material responds to oxidation / weathering processes over time, and are used to estimate the time until samples may start to produce acidity and the rates at which the samples release metals. Several mine rock kinetic testing programs will be conducted in 2023, including a program conducted in the laboratory (humidity cell tests) and a program conducted in the field (field leach barrel tests).
>
> • The humidity cell test program will be initiated in the laboratory in 2023. Ten tests are currently planned and the specific number of tests will be confirmed following receipt of the static testing results. Samples to be tested will include key mine rock materials with a risk for ML/ARD along with test samples that are representative of typical Project mine rock. Initial reporting on the humidity cell tests will be available in Q4 2023."
>
> • A field leach barrel program will be initiated in the spring of 2023. Ten tests are currently planned but the specific number of tests will be confirmed following receipt of the static testing results. The objective of this program is to evaluate rates of sulphide oxidation and metal release under field conditions. This information will be integrated with the results of ongoing laboratory humidity cell tests to evaluate lag times to acid onset and metal release from mine rock. The tests will be routinely monitored throughout the open water season in 2023. Initial reporting on the field leach barrel program will be available in Q4 2023."

It is now April 2024. Where are the progress reports "available in Q4 2023"? In any case, these tests take at least one year, and often longer, to complete according to the federal ML-ARD Prediction Manual (Price, 2009). Thus, reliable and professionally certified results will not likely be available until late 2024 or 2025 at the earliest.

Under "Overburden Characterization", it says:

> "A preliminary geochemical characterization program for overburden is underway. Thirty samples of the various types of overburden present around the property were collected as part of field work conducted in 2022. Samples were submitted to the laboratory for static testing (ABA and elemental content) and a subset of samples were selected for more detailed static tests. Results will be available in Q2 2023."

Strangely, in the September 2023 Reclamation Strategy (see next section), the preliminary results are mentioned for mine rock but not for overburden. This is important because this Project Definition estimates there will be about 200,000 tonnes of overburden disturbed (with recent documents less than a year later saying ~400,000 t). This is about three times more overburden than the ore being mined as a bulk sample. On average around Canada, about half of overburden at mineral deposits has significant ML-ARD potential, so there is a significant risk that Great Bear overburden will devastate water quality on, beneath, and around the site.

Under "Mine Water Quality Estimates", this Workplan states:

> "Mine water quality estimates for the AEX phase will be prepared in Q1 2023. Modelling will be conducted via mass balance approaches and will be supported by the AEX site water balance and available geochemistry data. The model results will be used to ensure that site water management needs are identified and addressed. Additional water quality modelling, representing the overall Project, will be undertaken at a later date as the project advances."

Mine-water mass balances are not often representative of leachates from sulphide-bearing rock and overburden as found at the Great Bear Project. There is no justification here for mass-balance modelling and its results could be irrelevant for Advanced Exploration as well as proposed mining. This approach should be examined in detail including the data on which it is based once qualified-professional-certified documents become available.

Under "Technical Data Collection Methodologies", it says:

> "The approach and methodology for the geochemistry programs were based on the requirements described under the Ontario Mining Act; namely guidance found within the documents DRAFT Guidelines and Recommended Methods for the Prediction of Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (Price 1997), and Policy for Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (MEM 1998). Additional guidance was provided by the reference document Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND 2009), which represents best practice and industry standard approaches and methodologies for ML/ARD sampling and characterization in Canada."

In fact, this is wrong. The Ontario Mining Act states:

> "The sampling program shall be conducted by a person who is qualified in Ontario … in accordance with a report prepared by William A. Price on behalf of the [federal] Mine Environment Neutral Drainage (MEND) program, entitled "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials", MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..."

Therefore, for the Great Bear Project, "[t]he approach and methodology for the geochemistry programs were based on" 1997 and 1998 British Columbia documents with only "guidance" from the federal Prediction Manual. In reality, the approach and methodology are required under the Act to be based fully on the 2009 600-page federal Prediction Manual, which instead was only used for "additional guidance". The 1997 and 1998 BC documents (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997) provided relatively little detailed instructions compared with the federal Prediction Manual, so the Great Bear ML-ARD testwork started off as likely insufficient under the Prediction Manual and would have to be expanded.

Under "Field and Laboratory Work Timing", it says:

> "Some field and laboratory work associated with the geochemical characterization programs was conducted in 2022 as described in the previous sections. Additional lab work is planned for 2023 as outlined above. Field work will be conducted in 2023 to construct the Field Leach Barrel tests and monitor and collect leachate from the tests. Reporting for the various programs will be available through 2023 as described above."

I have not yet seen this reporting from 2023 and am not aware if it has in fact been reported and

certified in 2023.

In summary, problems encountered in this January 2023 Geochemical Characterization Workplan include:

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross wants to proceed with Advanced Exploration.

- All that is available now is 96 rock core analyses according to the September 2023 Reclamation Summary (see below), which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". In any case, the 96 samples were not collected and analyzed as required under the Ontario Mining Act (see next bullet). Thus, Kinross Gold and WSP are guessing on how bad the contamination will be, but admit that some of it will be bad, and are likely years away from completing the ML-ARD work required under the Ontario Mining Act and its Regulation 240/00 (Mine Development and Closure under Part VII Of the Act).

- The stated approach and methodology used for Advanced Exploration is "based on the requirements" of two British Columbia documents from 1997-1998 (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997). In reality, the Ontario Mining Act says the approach and methodology must be based on the 2009 federal Prediction Manual, not just as "guidance" as Great Bear has done. Thus, the work for Advanced Exploration to date does not meet the Ontario Mining Act through Regulation 240/00 and does not meet the 2009 federal ML-ARD Prediction Manual (Price, 2009).

- Even if this Geochemical Characterization Workplan was applicable and consistent with the 2009 federal ML-ARD Prediction Manual, such work requires at least 2 to 3 years to obtain all required information and interpretations. Thus, perhaps in 2025 or some year after there might be sufficient ML-ARD for Advanced Exploration, but not any time soon.

4. Great Bear Advanced Exploration Program Reclamation Strategy (September 2023)

The Introduction of this document explains:

> "This memorandum was prepared to summarize the reclamation strategy for the AEX [Advanced Exploration] Program. The regulatory Closure Plan which will be filed with the Ontario Ministry of Mines is currently being developed. The purpose of this memorandum is to seek input from Indigenous communities regarding the proposed closure strategy for the AEX Program."

Thus, this memo is only to "summarize" the reclamation strategy in order to "seek input from Indigenous communities". As shown below, this summary is insufficient for Grassy Narrows First Nation to provide input and this reclamation "summary" in fact already reveals errors and misconceptions.

Section 2 entitled Project Information lists "major components" for Advanced Exploration. For tonnages and sizes, only the ore is mentioned and it will be shipped offsite. So there is no overall summary of areas, volumes, and heights of waste and disturbed materials remaining on site and requiring careful reclamation. This is important, because there will be at least 17 tonnes of mine waste rock generated for each 1 tonne of ore (see Sections 2 and 10 of this MDAG review), which is a substantial ore:waste ratio and one that requires intensive efforts to protect the surrounding environment. There would also be ~7 tonnes of overburden mined for each 1 tonne of ore, which increased through 2023 from an initial ~3:1 ratio.

Therefore, this Reclamation Strategy does not sufficiently protect the environment due to the lack of sufficient data, which is replaced by information that at best "suggests". The decision to mine a huge bulk sample of ore worth tens of millions of dollars, likely to offset exploration costs, has not been based on suggestions, so why are associated reclamation and environmental protection based on suggestions?

There is no explanation in this or other documents on why an underground bulk sample requires the destruction of surface vegetation and shallow soils to remove a relatively enormous volume of 400,000 tonnes of overburden (the most recent estimate, which had been increasing). Additionally, 96 ML-ARD samples are mentioned for rock "proximal" to the underground workings, but there is no mention of the 30 samples of overburden also tested for ML-ARD potential.

Because roughly half of overburden stockpiles at sites similar to Great Bear have significant ML-ARD potential, the Great Bear overburden should be assumed to have the same strong potential for water contamination and ARD (called "PAG" in this document) unless proven otherwise. It is alarming that Kinross Gold is assuming 100% of the overburden is environmentally benign.

Figure 2 of this Reclamation Strategy shows an unlined overburden stockpile where its seepage can contaminate local water and soil, and Figure 3 shows the overburden runoff and seepage is completely ignored. This serious omission can also be seen in Section 2.3 which ignores contaminant potential from overburden by simply addressing surface runoff and not subsurface

seepage and groundwater:

> "Runoff from the overburden stockpiles (will be monitored and treated to manage suspended solids as required and discharged)"

Section 2.1 on Underground Mining Methods Summary does not describe advanced exploration where a bulk sample of several tonnes is obtained and tested. Instead, Section 2.1 describes an initial four-year phase of mining of more than 1 million tonnes of waste rock and 200,000 tonnes (more recently, ~400,000 t) of overburden to obtain only 60,000 tonnes of ore worth tens of millions of dollars. In reality, four years of this type of advanced exploration is essentially being used as the first phase of the underground mine plan so that there is relatively little delay to start mining should the project be approved.

In the Project Definition (see Section 2 of this MDAG review), Kinross Gold provided three reasons for a relatively huge bulk sample along with 17 times more waste rock and now 7 times more overburden. However, as explained above, these reasons do not make sense. For example, Kinross says that bulk samples help to prove the continuity of underground access gold deposits and are very important to potential financiers. Yet, most of the proposed underground workings are focussed into two small lateral areas and not throughout the ore zone "to prove the continuity".

In Section 2.2 on Geochemistry Summary, it says:

> "The sampling approach and testing methods for the preliminary geochemical assessment are based on the requirements described under the Ontario Mining Act, namely guidance found within the DRAFT Guidelines and Recommended Methods for the Prediction of Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (MEM 1998)."

This same error occurs in the January 2023 Geochemical Characterization Workplan. The Ontario Mining Act through its Regulation 240/00 does not mention the 1998 British Columbia document. Instead, the relevant wording is:

> "The sampling program shall be conducted by a person who is qualified in Ontario … in accordance with a report prepared by William A. Price on behalf of the [federal] Mine Environment Neutral Drainage (MEND) program, entitled "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials", MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..."

Page P-24 of this 600-page federal Prediction Manual specified by the Ontario Regulation 240/00 says, "Major technical assistance was provided by Kevin Morin (Mine[site] Drainage Assessment Group)... and Kevin Morin provided major editorial assistance." Therefore, for the Great Bear Project, I can attest that "[t]he sampling approach and testing methods" are based on the wrong document.

Based on the 2009 federal Prediction Manual required by Regulation 240/00, the proposed ML-ARD work "in progress" is not sufficient, likely because the Manual was used by Kinross Gold only as "[a]dditional guidance" instead of a required document. This is easily seen in words like "preliminary geochemical assessment" and "initial evaluation". The ML-ARD predictions and information are the main basis for design of water treatment and for reclamation/closure. Thus, it is not acceptable for treatment and closure to be based on "preliminary" and "initial" information.

This can lead to misleading impact assessments and receiving-environment effects.

There are already errors in the Great Bear ML-ARD work as found in this Reclamation Strategy. These range from an incorrect definitions of the fundamental acronyms of "PAG" and "NPAG", to major problems with samples collected to date. For ML-ARD, all that is mentioned as of September 2023 is 96 rock-core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be mined during Advanced Exploration, but only "proximal" which could also mean "very different". Some percentage of this proximal rock, such as 50% to 67%, is considered not to have much ML-ARD potential based on "preliminary" data, but that is unreliable or wrong.

Kinross Gold is guessing on how bad the ML-ARD contamination will be, and admits some of it will be bad. However, it is likely years away from completing the appropriate ML-ARD work required under the Ontario Mining Act and Regulation 240/00, including the federal ML-ARD Prediction Manual (Price, 2009).

Section 2.4 of this Reclamation Strategy on Closure Objectives says:

> "The primary objective of closure is to rehabilitate the area to a long-term safe and sustainable state that considers the desires of local Indigenous land users to the extent practical (such as post closure land uses) by promoting vegetation communities that support habitat for local species diversity and aquatic habitat that will support healthy fish populations. The purpose of this memorandum is to seek input from indigenous communities regarding end land uses and closure concepts."

It is remarkable that Kinross Gold considers leaving "NPAG" rock perhaps with a cover of 0.3 m of potentially contaminated overburden, plus a large amount of stockpiled overburden at the surface, to be a "long-term safe and sustainable state...". To the contrary, this reclamation strategy can result in perpetual water treatment. A cover over "NPAG" rock does not stop ML and contaminated effluent, which could instead require perpetual water treatment. The closure plan and its estimated cost of only ~$10 million would not pay for this.

Section 3 on Progressive Rehabilitation Measures says:

> "Mine rock will be moved underground during the program as needed for use as road material, and potentially as backfill in underground areas for stability."

This issue arises later where "PAG" rock is proposed to be moved underground after mining of the bulk sample and the many underground workings. The seriously major problem here is that "PAG" rock can release relatively enormous amounts of heavy metals and other elements as it is flooded and submerged. This can create a toxic "soup" of underground water, worse than any seen at the surface, that eventually flows out into the surrounding environment and groundwater system. This would likely require long-term pump-and-treat remediation of the surrounding groundwater. Such pump-and-treat remediation is not included or costed in the ~$10 million total closure costs, and would likely cost much more than $10 million itself.

As part of closure, Section 5.1 says:

> "The portals will be backfilled with NPAG rockfill."

Because this rock will probably be an ML concern, including leaching heavy metals and other elements, backfilling the portals with this NPAG rock that will remain partially exposed and oxidizing will lead to perpetual ongoing water contamination. Adding to this contamination will be backfilled oxidized-and-contaminated PAG material that will likely release relatively large amounts of heavy metal and other elements. Contaminated water from this PAG material, backfilled into the underground workings and partially flooded to the maximum level, and from the NPAG material plugging the portals, would start flowing out of the mine area and into the surrounding groundwater system unless there is perpetual collection and treatment.

Section 5.6 on Soils Testing mistakenly says:

> "The primary soil contamination that could be expected from the AEX activities would result from the use / spillage of petroleum / diesel fuels. A soil sampling plan will be developed at the time of closure to evaluate potential hydrocarbon or chemical contamination, as appropriate."

In reality, the primary soil contamination would likely be from the elevated levels of heavy metals and other elements in wind-blown fugitive dust (see Section 8 of this MDAG review). This dust would come from the PAG and NPAG blasted-rock stockpiles, from the overburden stockpile(s), and from mine roads and building foundations made of the blasted rock and overburden.

Section 5.7 of this Reclamation Strategy says:

> "The primary long term closure concern with respect to the mine rock stockpiles is acid rock drainage and metals leaching. Preliminary geochemical investigations suggest that up to approximately 35% of the AEX mine rock could be PAG, as discussed in Section 2.2. During the AEX Program, the PAG and NPAG mine rock will be segregated in accordance with the AEX Mine Waste Management Plan, which is currently being developed at the time this document was prepared."

"Preliminary geochemical investigations suggest that..." is not acceptable for design of the waste-rock piles and the treatment system. Preliminary geochemical investigations can be seriously wrong and substantially underestimate contamination from the rock and overburden.

Section 5.7 also says:

> "It is anticipated that up to 127,200 m^3 of PAG mine rock will be stockpiled at the AEX Program and will need to be appropriately rehabilitated either progressively or at closure."

The closure costs from the Program Closure Plan (see Section 5 of this MDAG review below) show it will cost $30.00 per m^3 to relocate the PAG rock back into the underground workings, where it would then contaminate the underground water that will eventually flow into the environment. This would be a total cost of $3,816,000. However, Table 12-1 from the Program Closure Plan (issued two months after this Reclamation Strategy) estimates PAG rock higher at 191,000 m^3 (a remarkable 50% more) costing $5,730,000.

Section 5.7 also says:

> "The NPAG Stockpile footprint may be covered with up to 0.5 m of overburden and seeded for revegetation. Additional cover depth is provided overlying the NPAG Stockpile to account for potential losses to void spaces in the mine rock. It is anticipated that the overburden material will fill in the void spaces and support revegetation."

However, the overburden could have ML-ARD potential, and thus would not support vegetation but instead kill vegetation.

In summary of the Reclamation Strategy from September 2023,

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross Gold wants to proceed with Advanced Exploration.

- All that is available now is 96 core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". Also, 30 samples of overburden, which is intended to be left on surface and used for reclamation, were collected yet the results are not reported although there is ~50% probability that the overburden will release ML-ARD and thus be toxic. Kinross Gold and WSP are guessing how bad the contamination will be, but admit that some of it will be bad. They are likely years away from completing the ML-ARD work required under the Ontario Mining Act and its Regulation 240/00, because the work for Great Bear was not initially stated as consistent with Regulation 240/00. Even the definitions of ML-ARD acronyms used for the Great Bear Project are not correct according to the federal Manual specified by Regulation 240/00, which is additional evidence the Prediction Manual is not being followed.

- The bad ML-ARD rock appears to be associated with "rapid acid generation" according to the Program Closure Plan (reviewed in the next section below). This is an incorrect explanation of the phenomenon, but shows that the bad water quality will start coming out of the disturbed rock, including the underground mine walls, very quickly after initial disturbance. Informally, this is called "lag time" to ML-ARD, but most of the ML-ARD work has not yet been done to quantitatively estimate the lag time beyond "rapid". This contaminating rock will be stored on surface and possibly only later, likely after the lag time, some might be taken underground. When it contacts water underground as the workings partially flood and submerge, it will quickly release more contamination. This means the underground water moving into the surrounding groundwater system, and surface overflow if any, would have to be monitored and likely be treated for many years or in perpetuity after Advanced Exploration.

5. Program Closure Plan, Draft for Indigenous Review (November 2023)

This password-protected draft document for Advanced Exploration is only "for Indigenous review". This is odd to me since it is Kinross Gold's responsibility to design and justify the closure plan through certified professionals, rather than submit a draft to see if any First Nations notice the weaknesses and problems explained below.

In fact, since this draft report it is password protected, none of its content can be extracted for detailed re-interpretation and review. Thus, Kinross Gold is limiting the "Indigenous review" it is seeking.

In Table 5-3 entitled Approximate Mine Rock and Overburden Volume and Production Schedule in Section 5.7 on Mineral Materials Management, the total waste rock remains around 1,060,000 t relative to past documents (see the sections of this MDAG review above).

However, overburden has risen remarkably from past documents to "~170,400 m^3", expressed as m^3 instead of tonnes like the waste rock. It would be ~350,000 to ~400,000 tonnes of overburden. The overburden's ML-ARD status and its impact on water quality are poorly defined. This means that overburden at Great Bear becomes an environmental danger capable of substantial environmental impacts not currently identified or estimated.

Table 5-4 contains Preliminary Threshold Criteria for Segregation the AEX Program Mine Rock. The criteria for "PAG" do not say whether the criteria are "AND" or "OR", which is a huge difference and serious omission. Thus, ML-ARD is clearly still not reliably estimated, predicted, and understood at the Great Bear Project as of November 2023.

The text in Section 5.7.2 alarmingly says,

> "A preliminary sulphur threshold (TS) of 0.15% has also been proposed to differentiate between PAG rock and NPAG rock. The proposed threshold values are generally accepted as industry best practices in the absence of a site specific geochemical value."

No, 0.15%S is not "industry best practices". Quebec uses ~0.05%S and other provinces have not established a minimum value because technically there is no minimum value. Furthermore, it is rarely the sulphur level alone that distinguishes "PAG" (incorrectly defined in this document as "potentially acid generating" and "NPAG" (incorrectly defined in this document as "non-potentially acid generating"). Instead, according to the federal ML-ARD Prediction Manual (Price, 2009), the amount of Effective Neutralization Potential (ENP) plays a major role, as does site-specific criteria for the ENP-to-sulphur ratio.

This is explained in detail in the 600-page federal ML-ARD Prediction Manual that this ML-ARD work for the Great Bear Project is legally supposed to follow but does not. As a result, this "preliminary sulphur threshold" is an unreliable, questionable, and uncertified attempt to proceed with the design and planning for Advanced Exploration. Insufficient reliable information is available at this time, and even Appendix A "Certifications" is missing from this document. As a professional

in ML-ARD, I want to know the certified professional(s) who created these "preliminary" criteria.

"NML" is defined in this Closure Plan as "non-metal leaching" which does not apply to any rock in the world, as all rock is capable of leaching some metals and even nonmetals. In any case, "NML" in Table 5-4 for the Great Bear Project is rarely definable by the solid-phase level of a single element like "Arsenic < 30 mg/kg", but Kinross Gold does not know this because it has not yet completed the on-site and laboratory-based kinetic tests. If leaching were dependent on solid-phase levels as believed here, then Great Bear waters would contain thousands of mg/L of aluminum and silica because most of its rock is made of those elements. But this is not the case. This is why these are called "preliminary threshold criteria" in Table 5-4, which in reality are likely wrong and nonsensical.

Section 9.16 on Watercourses and Site Drainage contains Tables 9-1 to 9-5. Tables 9-4 and 9-5 contain predictions of on-site and effluent contaminant levels only after closure, which would obviously be much less than during active exploration. However, the text does not even discuss or explain Tables 9-4 and 9-5. They appear to be "thrown in" to appear complete.

Table 9-4 contains Geochemical Source Terms, which are the predicted aqueous concentrations for all contaminants in Great Bear water caused by Advanced Exploration. In reality, there are many problems with this Table 9-4 including:

- It does not include "PAG" concentrations which will be much worse and will be present for at least four years, because this Table is intended only for closure but alarmingly does not include the likely more severe PAG contamination when it is backfilled into the underground workings.
- It assumes closure drainage from "Covered and Revegetated Area" will be instantaneously at pre-exploration "baseline water quality", which is wrong.
- It shows elements likely requiring perpetual post-closure treatment include aluminum, antimony, arsenic, and selenium.
- It does not include predictions for many potential contaminants such as manganese, magnesium, sodium, potassium, barium, hardness, alkalinity, acidity, fluoride, chloride, bismuth, chromium 6+, lithium, silicon, strontium, tellurium, thorium, tin, titanium, and zirconium.
- It does not allow for federal emerging contaminants such as platinum-group metals and tantalum.
- It is based on a report "WSP 2023f" which is the draft "WSP, 2023f. Advanced Exploration (AEX) Phase – Preliminary Water Quality Estimate Update - Draft. WSP E&I Limited, April 2023". This report is only draft and thus is unreliable and not professionally certified.

Table 9-5 contains Mine Water Pond Overflow Estimated Water Quality which apparently would be overflow off the exploration site upon closure. It raises important questions, like how does aqueous sulphate decrease from 75-100 mg/L (Table 9-4) to 18-25 mg/L (Table 9-5) in mine-water-pond overflow when there is no treatment? In any case, some predicted concentrations are likely too high to discharge to the environment like arsenic. Also, sulphate reportedly increases the methylation of mercury and other elements.

Table 12-1 is the Closure Cost Estimate. The cost for moving PAG rock back underground is set at $30.00/m^3 which is ~$15.00 /tonne. The total waste rock from Advanced Exploration is estimated at 1,060,000 t. Kinross Gold currently guesses, based on preliminary uncertified information, the waste rock will be about one-third to one-half "PAG" requiring backfilling to the underground. Therefore, the cost for this task alone is $5,000,000 to $7,500,000 based on the unverified guess, and could reach a maximum of $15,000,000. Because the current Grand Total for Closure is estimated at ~$10,000,000, the backfilling of rock is the major cost item and could cost much more than the $5,730,000 currently estimated. In turn, Total Cost could cost many millions of dollars more than currently estimated from the guessed minimal amount. Put simply, closure costs are likely grossly underestimated.

All six appendices of this Program Closure Plan are missing, including professional certifications. This is likely not an error or oversight, meaning this Program Closure Plan should not be considered reliable and dependable.

In summary of the password-protected Program Closure Plan, Draft for Indigenous Review from November 2023,

- In November 2023, the volume of overburden has approximately doubled from previous documents without an explanation. Because overburden generally has a 50% probability of releasing ML-ARD and contaminating water, overburden represents a major but unexamined threat to water quality on, around, and beneath the Great Bear exploration site.

- "Preliminary" criteria are provided for separating "PAG" and "NPAG" rock and for "NML" rock. However, these acronyms are not used in an accurate manner consistent with the 2009 federal Prediction Manual (Price, 2009) required under Regulation 240/00. The preliminary criteria are not rational based on ML-ARD science unless justified with detailed and intensive site-specific studies, which have not yet been completed and certified for the Great Bear Project.

- The potential for ML-ARD after closure is presented all the way to detailed predictions of aqueous concentrations in mg/L for on-site water and effluent to the environment only after closure. However, these predictions are not explained in any detail, are not justified, appear anomalous, and are not certified by a qualified professional. Some predictions are actually pre-exploration baseline which are erroneously assumed to be re-established immediately at closure. Furthermore, these predictions are missing more than a dozen potential contaminants.

- The "PAG" rock, which would likely create the highest contaminant concentrations, is not included in this Program Closure Plan, presumably because this "PAG" rock will be backfilled underground. However, when placed underground, this "PAG" rock will likely continue to release severe ML-ARD until submerged, at which point a relatively huge amount of accumulated contamination would be released into the underground water. After the mine is refilled to equilibrium and the minewater begins flowing into the surrounding groundwater system and through the many permeable drillholes more than 500 km long to the

environment, it will contaminate large surrounding areas. This major risk to water quality and the environment is not even mentioned in this Closure Plan, which is a major omission.

- The backfilling of "PAG" rock at closure is the largest individual cost item for closure totalling around $10 million. However, this reflects the currently minimum volume based on preliminary, unreliable information. In the worst case, which was assumed for the Great Bear Project Definition and still not disproven, total closure costs could exceed $20 million.

6. Hydrogeological Workplan (December 21, 2022)

This Workplan for 2023 says:

> "The purpose of the program will be to develop a refined hydrogeological model of the site, support groundwater model calibration and be used for long-term monitoring. The information collected in the upcoming field surveys will supplement the existing information.... Hydrogeological testing and groundwater sampling will occur at specific locations near the Project site shown in Figure 1."

However, Figure 1 of the Hydrogeologic Workplan shows a major omission which would preclude fully meeting its purpose and objectives. The currently proposed mine plan shows the "Tailings Management Facility" extending at least 2 km to the west and northwest of Tear Drop Lake. Figure 1 shows that the Tailings Management Facility and its hydrogeologic effects would extend far beyond the western limit of the monitoring wells. Thus, many more monitor wells are needed westward and northward at least to Stone Lake, Gullrock Lake, and Genessee Lake.

In summary of this Hydrogeological Workplan from December 2022, there is a major omission that would preclude a reliable and comprehensive assessment of current baseline hydrogeologic conditions and of future impacts from proposed mining. The groundwater monitoring network does not extend far enough to the west and northwest, beyond the proposed western portion of the Tailings Management Facility.

7. Surface Water Quality Workplan (December 21, 2022)

This Workplan for 2023says:

> "Baseline surface water quality work has been ongoing for the proposed Great Bear Project (the Project) since 2020. This proposed workplan for 2023 is to gather supplemental water quality data that will be used to further support long term monitoring and the development of the Project."

This Surface Water Quality Workplan provides incomplete lists of important details prefaced by "including", like "These sampling locations include..." and "Standard suite of total and dissolved metals including...". This can lead to major problems in the future if a sampling location or water-quality parameter is missing.

For example, the "Standard suite of total and dissolved metals including..." does not mention important elements like manganese, titanium, thallium, and federal emerging elements like tantalum and platinum-group elements. Therefore, Kinross Gold is risking major omissions and flaws that can arise later by not being comprehensive in its "including" lists.

In summary of this Surface Water Quality Workplan from December 2022, there are insufficient information and details to determine if appropriate work is planned and conducted. This is because important details are listed only as "including". For example, major potential contaminants like manganese and thallium are not specifically listed, but perhaps they are implicitly included? There is no way to know.

8. Fugitive Dust Best Management Practices Plan, final draft (September 2023)

Section 4.5 on Material Stockpiles in this "Final Draft" states there will be two overburden stockpiles created during Advanced Exploration, one north of the mine-rock pile and another east of the crusher area. Some Great Bear documents reviewed above and the undated "AEX Site Plan - Updated.pdf" do not show this. Because the overburden has a general 50% probability of contaminating water and because overburden is specifically listed as a site component requiring ML-ARD evaluation and potential mitigation, this contradiction on overburden stockpiles is not acceptable. It further shows that Kinross Gold's ongoing issuing of "preliminary", "initial, and "draft" documents is causing confusion inside the project itself and thus should not be approved at this time.

Section 5.1 on the Composition and Characterization of Particulate Emissions contains a major error that would grossly underestimate the geochemical contamination of soil, vegetation, water, and biota by dust, and is thus not acceptable. Section 5.1 says:

> "Fugitive dusts from roadways and stockpiles may contain trace metals which may be considered negligible as these would be similar in concentration to the background rock."

The ML-ARD studies currently underway on ore, waste rock, and overburden have already shown that some material will contain substantial solid-phase levels of many elements and will leach to some degree. This is certainly not "background rock" as assumed in this fugitive-dust study. Therefore, fugitive dust should be an important component of impact assessment for Advanced Exploration and proposed mining.

Furthermore, proposed dust suppression by watering could lead to widespread metal leaching and water-quality degradation across and around the proposed exploration site.

In summary of the final-draft Fugitive Dust Best Management Practices Plan of September 2023 for Advanced Exploration, this work is unacceptable because it grossly underestimates the potential impacts from geochemical contamination of soil, vegetation, water, and biota by dust. This work assumes the on-site sources of dust "would be similar in concentration to the background rock". This is wrong and ignores the ongoing ML-ARD assessment of ore, rock, and overburden.

9. PTTW Application for Dewatering, final draft (October 2023)

This is one of the few Great Bear documents that provide names for the qualified person writing the report, appropriately signed as "DRAFT" at this time. However, the reviewer but not the author is a P. Geo. So additional information is needed on the qualifications and certifications of the author(s). PPTW stands for "Permit To Take Water", meaning using and removing water from the Great Bear site.

9.1 Main Report

The tone of this "final draft" report for Advanced Exploration is apparent from Section 1.1 on the Purpose and Scope of This Submission. It says:
"Water takings during the AEX Program will include:

- Water pumped from the underground exploration workings (underground dewatering)
- Incidental surface water and groundwater takings, expected to occur during excavation of water management ponds.
- Direct taking from Dixie Creek (up to 250 cubic metres per day; m^3/day) to be used for dust suppression, industrial activity (e.g. in support of development pad construction and packing) and advanced exploration drill water cooling (underground drilling).

"No other takings from other area waterbodies (lakes, rivers, streams) are proposed.

"Most of the dewatering water pumped from the underground exploration workings will be directed to ponds within the AEX water management system, treated and ultimately discharged to the environment to be approved under an Environmental Compliance Approval for Industrial Sewage Works (ECA ISW)"

First, note that the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning that the actual total water withdrawal from the local water balance, as shown in Table 4-1 (discussed below), would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these values are unrealistically low (see Section 9.2 below). This major withdrawal of water, that could upset and dewater groundwater zones like aquifers and surface waterbodies like creeks and lakes, is much more extreme that numerically indicated in Section 1.1. This justifies an impact assessment on the proposed Advanced Exploration, despite this final-draft document stating:

> "The AEX Program does not meet the requirements of the Impact Assessment Act, Physical Activities Regulations. A Federal Impact Assessment is therefore not anticipated to be required."

Second, note that the quotation above states that water taken from Dixie Creek would be used for "dust suppression" among others. As explained in the previous Section 8 of this MDAG review, adding such water to ML-ARD dust from ore, rock, and overburden could seriously degrade water quality throughout the site and surrounding environment. However, this major environmental risk

is not considered or even mentioned here or in the fugitive-dust study. In fact, it is unreliably assumed to be no environmental risk at all.

Third, the discharge of up to 7,703,000 L/day of water that is only partially treated (see the details in other sections of this MDAG review like Sections 5 and 11) into any receiving environment could cause significant impacts from (1) the physical volume of the additional water and/or (2) its altered chemistry from baseline with implications on the receiving environment and cumulative effects.

Table 4-1 on Requested Water Takings shows that the requested surface-water withdrawal from Dixie Creek is 250,000 L/day and an additional 170,000 L/day from pond excavations. However, more than 10 times this amount will be removed from the groundwater system every day. The additional groundwater withdrawal is estimated at 783,000 L/day from pond excavations, 2,000,000 L/day from underground pumping, and on perhaps 30 days each year an additional 4,500,000 L/day removed as a contingency. Furthermore, as explained below for Appendix B of this PTTW document (see Section 9.2 of this MDAG review), the groundwater model incorrectly underestimates the much higher inflows that would arise during desaturation of the overburden and the rock surrounding the mine inside its "Zone of Influence".

Total water withdrawal from the existing water balance could thus likely be much more than 7,703,000 L/day relative to the Dixie Creek withdrawal of only 250,000 L/day. All this water would be taken from the existing baseline groundwater/surface-water balance which has likely reached some type of baseline equilibrium over the last thousands of years. When up to 7,703,000 L/day or more is removed from this equilibrium, there could be major disruptions to local and regional surface waters and groundwaters.

For example, a significant portion of the underground pumping of more than 6,500,000 L/day could be pulled from Dixie Creek through the underlying groundwater system. Thus, "takings" from Dixie Creek could in reality be 250,000 L/day plus substantially much more than this through groundwater. "Takings" could also come from other streams, lakes, and groundwater zones like aquifers, despite this report clearly stating, "No other takings from other area waterbodies (lakes, rivers, streams) are proposed". This statement is not reliable and could be seriously wrong.

Section 5 of this PTTW Application discusses Potential Environmental Impacts, with Section 5.2.1 specifically on Dixie Creek. There appears to be significant confusion here on the impacts of dewatering the underground workings on Dixie Creek.

Part of this confusion arises in the false thinking that baseflow coming from groundwater is simply part of the total flow in Dixie Creek. In reality, groundwater baseflow likely has a different, more stable temperature and a different water quality than the surface water flowing past the Great Bear Project. Therefore, it is important environmentally and to the benthic ecosystem to consider baseflow coming from groundwater separately from surface flow already in the creek.

Another part of this confusion on the physical impact of mine dewatering on Dixie Creek is related to which surface flow is used. Section 5.2.1 uses Average Annual Flow, Low Flow Period Average Flow (March), and Low Flow 7Q20. These show that mine dewatering will reduce flow in Dixie

Creek by only 0.2 to 2.4%. Again, these impacts would be greater because the groundwater of Appendix B (see Section 9.2 below) has underestimated the amount of underground water that has to be pumped.

Table 5-2 is more relevant for Dixie Creek, also copied as Table 7-2 in Appendix B. It shows the important, separate baseline baseflow for Dixie Creek is 2,601,000 L/day. This is predicted to be reduced by 873,000 L/day during dewatering for Advanced Exploration, although this is likely substantially underestimated by the groundwater model. Thus, much more than 34% of Dixie Creek baseflow will be taken away by the mine, which would have significant adverse effects during drought periods and on the quality of the benthic aquatic habitat. Additionally, the baseflow for Unnamed Waterbody 3 (called "Dixie Creek Tributary (TL-3)" in Appendix B) would be reduced a substantial 55%. This justifies an impact assessment for the proposed PTTW Application.

It is very important to note that this PTTW Application for Dewatering, final draft, contains and is based on critical information in its Appendices. The following comments pertain to these appendices, which in turn shows the main report is not reliable and not reasonable as a PTTW Application.

9.2 Appendix B

Appendix B of this PTTW report is a "Draft" Groundwater Modelling Report to Support PPTW Application for Underground Dewatering Final Draft. It contains a serious error in the groundwater modelling that underestimates initial groundwater inflow rates and thus dewatering pumping rates.

Table 4-1 of the main report says 3,203,000 L/day of groundwater would be removed every day, reaching up to 7,703,000 L/day on some days. Table 6-2 of this groundwater appendix says that the groundwater grid, from Genessee Lake on the west to half of Rice Lake to the east, has total groundwater inflows and outflows of ~10,000,000 L/day. If this modelling were correct, this means that roughly 32% of all groundwater in the area of the Great Bear Project will be drawn into and out of the mine on a daily basis, with up to 77% drawn into and out of the mine on some days as a contingency. However, it could well be worse as explained next. This justifies an impact assessment for the proposed PTTW Application.

If dewatering starts and continues for several years as proposed for Advanced Exploration at the Great Bear Project, and later during the expansion of proposed mining, groundwater inflow will come from two basic sources. The first, initial inflow will predominantly reflect the desaturating drainage of pores in the overburden and fractures in the rock, which will be relatively high at first and then decrease. Notably, the modelling currently shows that the overburden will eventually be virtually 100% dewatered to its base. This is called "transient conditions" and reflects the "specific yield" of the overburden and the "storage coefficient" of the rock. As this first transient inflow slows, likely years after Advanced Exploration ceases, the groundwater inflow will then come from "steady state", reflecting the hydraulic gradients and the hydraulic conductivities.

This modelling for Great Bear in Appendix B and for the PTTW Application is solely "steady state",

with no high transient inflow considered and no values for specific yields and storage coefficients even mentioned. Section 6 of Appendix B on Groundwater Model Development is clear on this:

> "Groundwater modelling was conducted for two phases: pre-mining site conditions for model calibration and mine operations conditions to predict *groundwater discharge rate to the proposed fully developed and dewatered underground mine workings* [MDAG emphasis]. These numerical groundwater flow models consider 3D *steady-state flow conditions* [MDAG emphasis] and implement an Equivalent Porous Media (EPM) approach, which is deemed sufficient for characterizing the overall groundwater flow regime at the scale of this analysis."

Thus, groundwater inflows in the years of active mining during Advanced Exploration have been clearly underestimated by considering only steady-state inflows after the proposed workings are "fully developed". Also note the ambiguous and unjustified "deemed sufficient" for the overall "EPM" modelling of groundwater at the Great Bear Project.

Table 6-3 showed that pre-mining single-value "measured interpreted" baseflows at two locations agreed with the Simulated Baseflow reflecting only long-term steady-state conditions by 14% or better. These single-value baseflows were 2,281,000 L/day and 847,000 L/day, which are less than the total groundwater that would be pumped from the mine during Advanced Exploration. Thus, a concern arises on whether baseflows could be significantly decreased by this pumping during Advanced Exploration. The main report (see comments above in Section 9.1 of this MDAG review) says the (underestimated) pumping effect would be minimal on most statistical values of flow in Dixie Creek. It is not emphasized that pumping would substantially reduce baseflow, with differing water quality and temperature than the surface water, and would be even more significant during droughts.

Figure 6-6 shows that the pre-mining Simulated Groundwater Levels were often 5 to 10 m higher than Observed Groundwater Levels, showing a strong bias towards overestimated (higher) simulated groundwater levels. It is not clear if this suggests simulated hydraulic conductivities may be too low. In any case, this problem manifests in Figure 6-7 where the simulated levels around Great Bear and Dixie Creek are typically around 9 m too high, which incorrectly and falsely indicate Dixie Creek could not be significantly dewatered during pumping because the water table is simulated to be very high. This is probably why Table 7-2 shows that the substantial yet likely underestimated partial dewatering of Dixie Creek Tributary (TL-3) and baseflow of Dixie Creek is 55% and 34%, respectively, and these dewatering percentages could be much higher if modelling were more accurate.

Of note, Table 7-1 indicates dewatering of Dixie Creek is only 1% because it uses the average annual flow that includes the sum of all storm events. It does not consider lost baseflow during dry times when aquatic life, vegetation, and water quality can be more severely degraded. Again, the simulated groundwater levels around Dixie Creek and Great Bear are often modelled around 9 m too high and thus actual dewatering of creeks and lakes could be much higher than stated in this groundwater report. In this case, Section 10 incorrectly states and underestimates based on the modelling that:

> "At the end of the AEX project, when dewatering is at its maximum, the model simulates a baseflow reduction for the Dixie Creek of 8.5% of the estimated 7Q20 (10,368 m^3/d) and 1% of the average annual flow (114,912 m^3/d), which is unlikely to change the nature of the flow

regime in the creeks."

In Section 7.1 on Groundwater Inflow Rate and Zone of Influence:

> "... the simulated long-term groundwater inflow rate into underground mine workings is 1,920 m^3/d [1,920,000 L/day]. This estimate of groundwater inflow into the fully developed mine does not consider uncertainty, seasonal variations or any loss from aquifer storage."

This simulated inflow is consistent with the estimated 2,000,000 L/day requested "taking" in the main report and in Table 8-1. However, the occasional contingency of 6,500,000 L/day which is apparently from "uncertainty, seasonal variations or any loss from aquifer storage" is relatively major. It highlights the expected variability of withdrawals and discharges of water into the surrounding environment during Advanced Exploration. Moreover, the reference to "aquifer storage" highlights the failure of the modelling to consider higher-inflow transient conditions which would be most important in the early several years of Advanced Exploration.

However, even ignoring the important high-flow transient conditions, Table 7-1 shows that the steady-state 2,000,000 L/day can be easily exceeded by non-base-case conditions like three-times-higher hydraulic conductivity of bedrock and by the water-conducting LP Shear Fault 1.

Section 7.1 explains:

> "The model-predicted Zone Of Influence (ZOI), defined here as 1 m drawdown of head in the glacial till unit is shown in Figure 7-1. The ZOI is predicted to extend about 1.2 to 2.5 km from the centre of the AEX site to surrounding environs."

Using the 1 m drawdown contour is not appropriate here, because modelled groundwater levels are already around 9 m too high and because Figures 4-9 and 4-12 show that some shallow groundwater levels can vary by 1 m naturally. Thus, the Zone of Influence could turn out to be much larger and thus affect lakes and creeks. In any case, even a 1 m decrease in groundwater level beneath a creek or lake can lead to substantial dewatering.

Figure 7-1 shows Simulated Drawdown Contours in Glacial Till. However, drawdown is only shown as a maximum of around 36 m, which is obviously not correct for dewatered drifts up to 600 m deep. Moreover, the maximum drawdown of 36 m in the overburden means most of the pores of the overburden would be primarily drained into the mine, which occurs during the ignored transient conditions.

The apparent explanation for the discrepancy between the maximum 36 m drawdown and the dewatered workings 600 m deep is that the drawdown in the bedrock is not shown, but would locally obviously be around 600 m. This 600-m drawdown would likely create a relatively huge drawdown zone in bedrock around the Advanced Exploration and the proposed mine extending for many kilometers around. This would be much larger than in the Zone of Influence in the overburden shown in Appendix B Figure 7-1. This justifies an impact assessment of this proposed dewatering since many impacts of the dewatering have been ignored or underestimated.

9.3 Appendix C and Its Several Draft Monitoring Programs

Appendix C contains draft monitoring programs. The "Working Draft" AEX ISW Groundwater Monitoring Plan, like many other Great Bear documents, ignores the overburden that likely has ML-ARD potential and can seriously contaminate water. This lack of consideration for potentially contaminating overburden can be seen in Figure 1-7 Water Management Schematic that has no mention or recognition of the overburden stockpile(s). The same is noted in Figure 1-6 of both the "Draft" ECA ISW - Advanced Exploration Surface Water Monitoring Plan Draft and the "draft" AEX ECA ISW Aquatic Resources Monitoring Plan in Appendix C.

9.4 Appendix D

Appendix D Consultation Records is missing from this file.

9.5 Summary

In summary of this PTTW (Permit To Take Water) Application for Dewatering, Final Draft, and its several important appendices from October 2023, there are alarming errors and ambiguities that should preclude approval of PTTW. These should also trigger a detailed impact assessment, which this PTTW report conversely says is not needed for Advanced Exploration at Great Bear.

In the introduction to the main PTTW report, the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning because the actual total water withdrawal from the local groundwater/surface-water balance would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these values are unrealistically low as explained here.

The errors begin with groundwater modelling that is based on long-term "steady state conditions" after the mine is "fully developed" and dewatered, and not on the correct, higher-inflow "transient conditions". Thus, inflow, pumping, and dewatering are significantly underestimated by the groundwater model and the PTTW Application. Additionally, there are problems with unrealistically low estimated effects on partial dewatering of Dixie Creek and other creeks and rivers. For example, simulated groundwater levels are modelled around 9 m higher than measured around the mine and Dixie Creek, which artificially and incorrectly prevent additional dewatering of Dixie Creek.

Groundwater levels are shown to be drawn down during dewatering to a maximum of only 36 m even though the dewatered workings will be 600 m deep. This reflects (1) nearly fully dewatering of the shallow overburden and (2) the lack of admission on the likely huge drawdown and much larger "Zone of Influence" in the rock beneath the overburden.

Baseflows into Dixie Creek and other waterbodies can be critical to aquatic, benthic, and terrestrial ecosystems because of groundwater's typically different water quality and temperature compared to water already flowing at the surface. This becomes more critical during droughts when baseflow

may be the main source of surface flows. The PTTW Application ignores the fact that more than 34 to 55% of existing baseflow would be lost during Advanced Exploration. It instead points out that the loss to groundwater would be only 2.4% and less of total flow depending on the chosen surface-flow statistic.

Overburden is routinely ignored in this PTTW document and its appendices, despite the proposed hundreds of thousands of tonnes of overburden likely having at least some ML-ARD potential and capacity to degrade water quality. In fact, some of the underground dewatering would be sprayed on the overburden for dust suppression, which in turn could lead to contaminated runoff across and off the site.

10. Draft (?) Detailed Project Description (November 2023)

In June 2023, Kinross Gold released the [final] Initial Project Description for the Great Bear Gold Project. Five months later, Kinross Gold issued the Detailed Project Description, where the first cover page showing "Kinross" says "DRAFT", but the second cover page for WSP E&I Canada Limited does not say "Draft".

The Kinross/WSP documents reviewed so far for proposed exploration and proposed mining are a mess with confusions over draft, preliminary, initial, and final. There is no reliable way to know what information issued by WSP and Kinross is considered final, reliable, and still applicable. In my opinion, all reviews for Great Bear should stop until Kinross Gold and WSP identify the final designs and plans for proposed exploration and proposed mining. Only then should they issue the final documents, signed and approved by qualified professionals.

Because the Initial Project Description was followed five months later by this perhaps-draft-perhaps-not-draft Detailed Project Description that apparently includes responses to Initial concerns, only the latter document is reviewed here.

10.1 Section C.3.3 Proposed Mine Facilities and Infrastructure

Section C.3.3 and Table C.1 provide a detailed list of all proposed mine facilities, many of which would be created during Advanced Exploration, which as explained above is closer to a first phase of mining. Many of the listed facilities require ML-ARD assessment including all under the headings of Underground and Open Pit Mine including mine walls and sumps, Stockpiles including overburden and waste rock, Tailings and Site Water Management including ditches, Aggregate Supply, Waste Management, Fuels and Reagents, all access roads and haul roads, all excavations and foundations for buildings, facilities, pipeline corridors, upgrades to bridge crossings, and the core shack including core-storage areas. Because these ML-ARD assessments are not completed at this time, it is prudent to conduct an impact assessment on all these components.

The Stockpiles section says:

> "Stockpiles will be created on the surface near the mine to store ore, mine rock, and overburden / organics resulting from site and mine development. Preliminary storage capacities of the stockpiles for the Project are the following, subject to revision as a result of ongoing exploration and technical studies:
>
> - Run of mine (i.e., uncrushed rock as transported from the mine) ore stockpile: approximately 0.1 to 0.5 million tonnes (Mt)
> - Low grade ore stockpile: approximately 5 to 20 Mt
> - Mine rock stockpile(s): approximately 210 Mt
> - Overburden / organics stockpile: approximately 40 Mt."

Thus, upon full mining, there would hundreds of millions of tonnes of mine waste, with most of it likely remaining on the surface and requiring perpetual maintenance. Additionally, low-grade ore

stockpiles are sometimes left on site after closure as waste-rock dumps. Because of this, some jurisdictions require financial assurances on perpetual maintenance of the low-grade dumps until/if they are processed. This should also be done for the Great Bear Project.

> " Based on the scale of the stockpiles and the environmental baseline studies which are in progress, it is expected that one or more of the Project stockpiles will overprint minor creeks which may contain fish."

Thus, there will be "overprint" impacts through destruction of fish, fish habitat, and associated water quality.

The Ore Processing section says:

> "Ore processing will entail several stages of conventional mineral processing such as grinding and classification, and cyanide leaching to separate the gold / silver from the gangue leading to production of doré bars."

Thus, the processing will add contaminants including cyanide and accelerated leaching of metals and other elements that will contaminate the water in the process, in the tailings impoundment, and in the fugitive seepage that will flow into the environment.

Also:

> "There are no sources of mercury from the ore processing."

This appears impossible because the ore rock going in, and the tailings and concentrate coming out, of ore processing should and will contain some level of mercury. The processing could even increase the solubility or leaching rate of mercury and other elements. Therefore, this appears to be an error unless Kinross Gold can prove the tailings and concentrate from the ore processing contain absolutely no mercury. This is highly unlikely if not impossible to prove.

The section on Tailings Management explains:

> "The primary by-product of ore processing is tailings. Tailings consist of ground rock and associated process effluents that result from the processing of ore. Tailings will be treated for cyanide destruction before storage. As part of the ongoing geochemistry investigations it was determined that the tailings may be potentially acid generating, Kinross is investigating the potential to desulphurize the initial tailings stream resulting in a non acid generating flotation tailings, and a smaller quantity of sulphide tailings that would be managed in a manner to mitigate their acid generating potential."

Cyanide destruction is rarely perfect and sometimes simply converts the cyanide to thiocyanide or cyanate which can then revert to cyanide after release to the environment. Because the details of Great Bear's cyanide destruction are not given, it is prudent to assess it for potential environmental impacts.

Tailings Management further says:

> "Tailings will be transferred from the processing plant to an onsite surface management facility as a slurry, or potentially as a filtered cake. A quantity of the tailings will also be sent to a paste backfill plant where they will be mixed with a binder (such as cement) to increase their strength, so that they can be returned to the underground workings to provide additional underground stability. Tailings could also potentially be stored in the open pit after mining

is complete.

Tailings paste backfill, dewatered filter-cake tailings, and the relocation and in-pit disposal of tailings each could have unique adverse impacts on water quality and this should be assessed by Kinross Gold.

> "Further detail on tailings management facility, including dam designs as applicable, will be developed as engineering progresses for the Project. The facility will be designed in accordance with all regulatory requirements including the Canadian Dam Association Dam Safety Guidelines as applicable."

Thus, the details for evaluating potential environmental impacts will not be available until "engineering progresses", which is consistent with the ML-ARD work which will not be completed for at least a few years.

Notably, this section on Tailings Management has no detailed description of water management including any water recirculation. This is a major omission that precludes a reliable assessment of impacts from how much water would be needed daily to run this proposed mine.

The section on Buildings and Yard Areas states:

"The following new permanent facilities are planned for the Project:

- Process plant and crusher / conveying system
- Mine office / dry / maintenance / wash bay complex
- Cold and warm storage buildings
- Reagent storage facilities
- General laydown areas and parking
- Additional core shack, laboratory and outbuildings
- Accommodations / camp
- Explosives storage facilities.

These will be supported by related road, piping and power infrastructure as needed."

The disturbed rock or overburden used in any of these Areas requires an ML-ARD assessment as explained in the 2009 federal ML-ARD Prediction Manual (Price, 2009).

The section on Water Management Facilities and Drainage Works explains:

> "Kinross proposes to establish an integrated water management system for the site to manage contact water from the underground mine, open pits and surface facilities. The underground mine will intercept groundwater, while the open pit will collect groundwater, runoff and direct precipitation. Mine water from the required dewatering of the underground mine and open pit, to enable mining to occur will be collected in sumps and pumped to the surface for additional management. The mine water management and treatment infrastructure developed for the AEX program is expected to be re-used at the beginning of operations and will potentially be incorporated into the overall integrated water management system for the operating mine.
>
> "Precipitation and surface runoff that comes into contact with mine-related facilities on surface will be collected in ditches and collection ponds designed. As needed, the water will be directed to the integrated water management system for treatment and discharge with

other site contact water.

> "The integrated water management system and associated effluent treatment plant will be designed and operated to ensure that effluent from the site meets all regulatory requirements and can be discharged to the environment. Effluent will be discharged to the Chukuni River a large watercourse with high assimilative capacity. This will allow continued use of the pipeline corridor established for the AEX program. The additional infrastructure required for the mine has not yet been determined."

This section on Water Management Facilities and Drainage Works does not explain the storm return periods for which the drainage works would be sized. Nor does it specify the design return period for the post-closure water management, such as the 24-hour 1-in-200-year precipitation or the Probable Maximum Flood. This is a major omission that precludes a reliable assessment of impacts from storm events that could lead to spills of contaminated site water, and thus confuses the decision on whether an impact assessment should be conducted.

Under Access and Site Roads:

> "A network of roads of will be established within the site as needed, minimizing water crossings. New roads will be constructed of aggregate or non-potentially acid generating mine rock. New major road and watercourse crossings are not expected for the Project, although minor crossings and cross drainages may be needed. The water pipeline corridor which will be developed for the AEX program, and potentially expanded with additional pipelines for the mine, includes an access road to allow for pipeline inspections, environmental monitoring and maintenance, and is expected to cross four headwater creeks / low-lying swales, likely as culverts (Figure C.1 and Figure C.2). The existing prefabricated truss bridge across Dixie Creek may be upgraded."

Any surface and subsurface disturbance including new roads require ML-ARD assessments before an impact assessment can be done according to the 2009 federal ML-ARD Prediction Manual (Price, 2009).

The Section on Aggregate Operations contains a serious error:

> "Aggregate will be required to develop the Project. The primary source of material is proposed to be *nonreactive mine rock and overburden* [MDAG emphasis] from stripping and other construction activities within the site. There are licensed commercial aggregate pits nearby (along Tuzyk's Road) that also represent a potential source of aggregate for the Project. Discussions with the owners of these aggregate facilities are planned to explore potential commercial arrangements.
>
> "New quarries for crushed rock and sand and gravel pits may be established on the Property if needed under the care and control of Kinross. Locations are not as yet known but may be situated at future development locations (such as within the tailing management area)."

Because there is no such thing as "nonreactive mine rock and overburden", then there will be no aggregate which is "required to develop the Project", which in turn literally means there can be no Great Bear Project or mine. This illustrates how Kinross Gold is submitting perhaps-draft

documents with statements intended to alleviate concerns that are instead false and misleading.

This document is not signed and certified by Qualified Professionals, so at least portions of this Detailed Project Description are more akin to Public Relations than technical accuracy. Grassy Narrows First Nation should be aware of these false statements in important documents supposed to describe accurately and reliably the proposed exploration and proposed mining of the Great Bear site. It is not prudent to decide impacts of proposed exploration and mining based on false technical statements.

10.2 Section C.3.4 Preliminary List of Mine Activities

This section C.3.4 lists many "preliminary" activities during Construction, Operations, and Decommissioning and Closure. While many sound like generally good ideas, they can turn out to be bad ideas and not even possible at the Great Bear Project.

For example, here are some "preliminary" activities:

> "Overburden and organic material from the open pits will be either stockpiled or used for progression reclamation"
>
> "Mine rock extracted from the underground workings and open pits will be stockpiled, re-used as aggregate, or potentially re-used a consolidated rockfill underground"

The Project Definition Document of December 2022 assumed all the mine rock would have strong ML-ARD potential and would substantially contaminate water. Overburden was not even assessed although required by Ontario Regulation 240/00. It is understandable that the initial worst-case scenario may be modified as years go by and as ML-ARD studies are completed according to the 2009 federal ML-ARD Prediction Manual. However, there may be little change from the worst case at the Great Bear Project, but no one knows at this time. Thus, these "preliminary" activities can cause wider and worse impacts; no one knows at this time. Nevertheless, this perhaps-draft Detailed Project Description lists them anyway without pointing out their potential for adverse impacts.

This section also says,

> "As operations continue the open pit will have a progressively larger surface area and will become deeper"

The proposed pits are a concern to me as I do not see them justified by Kinross Gold. In fact, Figure C.5 shows that most of proposed pits and excavations are not needed to access most of the ore. Thus, there seems to be another, unstated reason for them, but I cannot see what it is.

10.3 Section C.3.5 Preliminary Decommission Approach

This section says:

> "Decommissioning and final closure of the Project site will be governed by the Ontario Mining Act, and its associated Regulations and Codes, and will be informed by ongoing engagement with Indigenous Nations and potentially affected stakeholders. The Act requires

> that a Closure Plan be filed for mining project before construction, and that financial assurance be provided so sufficient funds are in place to carry out the decommissioning activities.
>
> "A preliminary description of the proposed decommissioning and reclamation measures is provided in the text that follows. The preliminary measures are subject to consultation, additional engineering and regulatory review. The active phase of decommissioning and reclamation is expected to be completed within approximately three years of the end of operations. Environmental monitoring will continue after reclamation is completed, until such time as the closure objectives as determined in the Closure Plan have been achieved."

It is important to note that this preliminary closure plan, which should include early and unexpected closure but does not, will determine the initial financial security. Thus, all potential major sources of contamination should be identified and costed now, but this is far from the case.

Many serious long-term concerns are omitted and thus cannot be added at this time to the cost of the initial financial assurance. For example, the section on the Underground Mine does not mention the costly and serious water-quality degradation that would likely accompany the backfilling of "PAG" rock into the mine, where the rising, flooding water can become seriously contaminated beyond that seen at the surface. This seriously contaminated flooding water would likely eventually reach an equilibrium level where it would begin flowing out into the surrounding groundwater system and the environment years after closure. This would require long-term or perpetual pumping and treatment of groundwater, which could substantially or enormously raise the financial assurance.

Alternatively, the "PAG" rock (and overburden) could be kept in a stockpile at the surface where its ongoing seepage of infiltrating water through some type of cover would require perpetual collection and treatment. This section implies the ML-ARD would stop by incorrectly saying:

> "Reclamation measures will be designed to mitigate acid mine drainage / metal leaching concerns as needed. This may include design and placement of an appropriate cover over the mineral waste."

ML-ARD is not mitigated cheaply and permeable covers do not stop infiltration but may reduce it if well maintained in perpetuity, still leading to perpetual maintenance and water treatment. Very expensive impermeable covers may virtually encapsulate and isolate the contaminating rock and overburden if carefully maintained in perpetuity, which also includes additional costs for perpetual maintenance and repair.

Or perhaps as Section C.6 on Potential Alternatives states, the mine rock would be used as "reclamation material" where it could contaminate more of the site. Or the mine rock would be placed into "storage in depleted open pit". In the pits, the backfilled mine rock would contaminate inflowing water that would eventually fill and flow into the surrounding environment, or eventually drain down into the underground workings where the second paragraph above explains the fate of the underground water.

One way or the other, the closure cost only for the rock and overburden alone will likely be much higher than envisioned in this perhaps-draft Detailed Project Description.

There are other examples like this that are not recognized and costed in this Section C.3.5.

Therefore, whatever the current estimated cost of financial assurance based on Section C.3.5, it should be raised substantially higher. This would also cover the expense should early or unexpected closure occurs, which is credible and often expected but is not mentioned or considered in this Great Bear document.

10.4 Section F Potential Effects of The Project

Section F on potential effects of the project during Construction, Operations, and Closure starts with Table F.1 Preliminary List of Change to the Environment under Federal Jurisdiction.

The row of Table F.1 for the Fisheries Act during the Construction Phase says:

> "Alteration, disruption and destruction of fish and benthic fauna habitat from direct disturbance (including potentially from overprinting by mine rock and tailings management facilities), blasting and mine dewatering" with the Preliminary Area of Influence only "Project footprint"

For mine dewatering, the ongoing drawdown of groundwater and ongoing dewatering of surface waterbodies does not stop immediately as the pumps are turned off at the end of Operations, but can continue for many years afterwards through Closure. Also, the Area of Influence could be much greater than the Project Footprint (see Section 9.2 of this MDAG review). However, Operations and Closure does not mention this long-term ongoing impact. This illustrates how "Preliminary Changes" are only partially recognized in this Detailed Project Description, and important ones are not mentioned and considered.

Additionally, for Closure under the Fisheries Act Table F.1 says:

> "Potential for creation of fish habitat in new pit lakes, expected to be re-connected to the Dixie Creek system"

This shows a lack of understanding of water-quality impacts and ML-ARD, similar to the Great Bear "nonreactive mine rock and overburden" that does not exist (see Section 10.1 of this review). It sounds good to non-technical readers to say the pit lakes will be fish habitat and "re-connected" to Dixie Creek although they are not currently connected. On the other hand, technical readers know this is highly unlikely considering the type of rock and ML-ARD likely to come from Great Bear rock, pit walls, and underground mine walls. These Great Bear pits as proposed, long after Closure, should not be expected to meet the requirements of the Fisheries Act.

Table F.2 Preliminary Summary of Potential Environmental Effects says:

> "- Underground mine and open pit dewatering will affect the local groundwater levels and may affect surface water flows
> - Groundwater quality is not expected to be affected"
>
> "Preliminary Areal Extent:
> - Dewatering may result in a depression in the local groundwater level which is currently under investigation"

Section 9.2 of this MDAG review explains how Kinross Gold's groundwater modelling is aware of, but avoids showing, the substantial lowering of groundwater levels by dewatering to a remarkable depth of ~600 m in the rock, while the overlying overburden is virtually fully dewatered to its base. This dramatic lowering will be much more than the comfortable sounding word of "local" in the above quotations. It will be much worse than "local". This will also likely have a major impact on groundwater quality, as Section 9 of this MDAG review explains, despite Kinross Gold's unjustified and unreasonable expectation that "Groundwater quality is not expected to be affected".

Furthermore, surface creeks and lakes could be dewatered much more than modelled because modelled groundwater levels are simulated around 9 m higher than measured, reducing the modelled and predicted dewatering below reality. Baseline flows to local surface waterbodies, which are critical to the benthic ecosystem and aquatic life due to their differing chemistry and temperature, will be reduced by 34% and more, but no one yet knows how much more.

Section F.6.1 on Atmospheric Emissions has a major omission that shows the environmental impact from atmospheric emissions would be much greater than stated. Section 8 of this MDAG review has explained that fugitive dust at Great Bear, and any water used to suppress this dust, would have a substantially larger environmental impact than currently recognized and modelled. Thus, impacts from air emissions have been underestimated in this Detailed Project Description that could be used to determine an impact assessment.

Section F.6.2 Liquid Discharges states:

> "Mine water will contain suspended solids from mining and earthmoving activities, ammonia residuals from ammonia-based explosives, and residual hydrocarbons from heavy equipment operation. Leaching of the exposed bedrock within the underground mine and open pit may potentially contribute minor quantities of metals to the mine water."

This is another example of bad science appearing as technical information in this perhaps-draft Detailed Project Description.

- First, underground mine water will also contain dissolved metals and other inorganic contaminants.
- Second, since ammonia is expected to be so high from underground explosives that a special treatment circuit is needed for it, then the always accompanying high nitrate and nitrite that will not be treated but discharged to the environment will also be high and contaminating.
- Third, since underground mine water will contain hydrocarbons, why is there no option to treat these potential organic contaminants?
- Fourth, leaching of mine walls in underground workings and open pits can, and elsewhere have, seriously contaminated the mine water, with the contamination increasing as the area of mine walls increases during mining. This could happen at Great Bear because more than 10 km of underground workings would likely be mined. However, the ML-ARD testwork to predict this under the federal ML-ARD Prediction Manual will be in progress for at least a few years. So, once again this Detailed Project Description misleads by already concluding that the leaching "may potentially contribute minor quantities of metals to the mine water". The reality could just as easily turn out to be "the leaching will contribute substantially high and toxic quantities of metals to the mine water". No one knows yet, not even Kinross Gold and its consultant, WSP.

Some day in a future year, reliable "Modelling will be completed to assess the volume and quality of the water requiring management, which will be used in the design of the integrated water management and treatment facilities on site." At this time, the groundwater requiring management has clearly already been underestimated (see Section 9.2 of this MDAG review). Until then, no one knows with reasonable confidence how much water has to be treated, how severely it will be contaminated, and how thoroughly it will be treated.

The subsection on Process Plant says:

> "Excess process plant water is expected to be pumped with the tailings to a tailings management facility for storage. The tailings and process plant water will contain metals from the processing of metal-containing ore and residual processing reagent products. A cyanide destruction circuit will be established within the process plant to treat residual cyanide concentrations in the tailings and process plant water, prior to pumping to the tailings management facility."

A major aspect of water management and tailings management is the percentage of discharged process water that will be recirculated back to the process to minimize freshwater usage and contamination by "metal from the processing". This issue is not mentioned and thus is a serious omission. Additionally, "cyanide destruction" is not perfect and may not literally destroy cyanide but temporarily mask it until its release to the environment. These important issues are not mentioned either. Thus, this quotation gives the false impression that cyanide and metals will only be "residual" and will be treated to minimize them, but this is simply guessing that is not consistent with ML-ARD testwork so far.

Section F.6.4 on the Environmental Management System does not explain the currently likely scenario that one or more additional contaminants not currently recognized will arise in on-site water (see also Section 11 of this MDAG review). This would require at least months of storage of contaminated water on site until the treatment plant is expanded and updated. Therefore, the on-site storage of months of site-contaminated surface water and groundwater should be a major objective of the Environmental Management System.

10.5 Summary

In summary of this perhaps-draft Detailed Project Description of November 2023, the first cover page by Kinross says this document is "draft", but the second cover page by the authors, WSP, does not say "draft" so perhaps this is the final document. If so, it has not been signed by qualified professionals and thus should be rejected.

In any case, there are so many problems, misleading statements, errors and omission concerning ML-ARD, water quality, and environmental impacts that they cannot all be summarized well here. These problems include the following.

- The false statement that there will be no sources of mercury from the ore processing when in fact the tailings and concentrate from the process will contain mercury. The processing could even cause mercury and other elements to leach more quickly and become more mobile.

- Contrary to the impression given by this Detailed Project Description, cyanide destruction is not perfect and can simply mask the cyanide temporarily in the environment, but the important testwork to determine this has not yet been done for the Great Bear Project.

- Significant impacts on water quality can arise from seemingly benign proposed activities like paste backfill of tailings into the underground mine and dewatered filter-cake tailings, but the potentials for serious impacts are not recognized or not even mentioned in this perhaps-draft Great Bear document.

- Storm events and equipment upsets can lead to relatively large variations and unexpected impacts, day-to-day or even hour-to-hour, during proposed exploration and proposed mining. Instead, these Great Bear documents use averages like monthly which incorrectly assume flows will be the same every day of a month which is far from reality. Environmental impacts and spills can be caused by large variations, as well as longer-term averages, so the environmental risks of proposed exploration and proposed mining at Great Bear remain mostly unknown and not identified.

- Nonsense pseudo-scientific statements are used, like the aggregate required to build the Great Bear Project would be "nonreactive mine rock and overburden" which does not exist. This clearly shows that experienced and qualified professionals were not included in the writing of this perhaps-draft Detailed Project Description. If there is a true commitment to "nonreactive mine rock and overburden" which does not exist, then the Great Bear Project stops now.

- There is a lack of ML-ARD assessments for some site components like aggregate.

- There is a prevalent but likely false belief that "NPAG"rock will have little to no impacts on ML-ARD, water quality, and the environment. However, this has not been proven for the Great Bear Project and is likely wrong based on other minesites around Canada. "NPAG" rock can actually generate more acid than "PAG" rock and still release seriously contaminated levels of many metals and other elements at near-neutral pH.

- The financial assurance to ensure proper and fully paid closure of the proposed Great Bear Project is grossly underestimated based on existing information. Furthermore, the financial assurance should also include contingency costs for early or premature closure but it does not.

- There are likely devastating, expensive, and unrecognized ML-ARD consequences on water quality from the proposed relocation of "PAG" rock into the underground workings after operation.

- The ongoing, unproven, and likely wrong, belief continues that overburden would be environmentally benign, can be used across the site for reclamation, and can be sprayed with water to control dusting when it could instead create contaminating water around, below, and beyond the Great Bear site.

- There are unfounded beliefs that dewatering during exploration and mining would have minimal

effect on the local and regional water balance, and would not significantly dewater surface creeks and lakes including their environmentally important baseflow. These false beliefs are based on flawed groundwater modelling for the Great Bear Project explained earlier in this MDAG review.

- There is a false belief that dust blown off the site during proposed exploration and proposed mining and into the surrounding environment, vegetation, soil, water, and aquatic ecosystems is benign at "background" levels.

- A false belief is stated that only elevated and toxic ammonia, and no other contaminating nitrogen species from explosives that consistently accompany the ammonia, will appear in mine water during proposed exploration and proposed mining.

- There is an unsupported and likely substantially underestimated statement that the mine walls in the pits and underground workings "may potentially contribute minor quantities of metals to the mine water" instead of the more typical significant quantities of metals seen at many other minesites around Canada. This is taken to the likely ludicrous statement that there would be "Potential for creation of fish habitat in new pit lakes, expected to be re-connected [sic] to the Dixie Creek system".

- There is no recognition of the implications, costs, and impacts of storing months of contaminated mine water on the site should one or more "unexpected" yet currently predictable inorganic contaminants and ML-ARD occur on the site water during and after proposed exploration or proposed mining.

11. Water Treatment during Proposed Exploration and Proposed Mining

Most of the contaminated water at the Great Bear Project during proposed exploration and proposed mining would be subjected to water treatment. There would remain some fugitive contaminated water and contaminated dust that would impact the surrounding environment. This fugitive contamination has not been assessed in detail by Kinross Gold, and is even ignored or not recognized in several Great Bear documents as shown above in this MDAG review.

If fugitive contamination turns out to be minimal, then water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts. Therefore, proposed water treatment should be examined and justified in great detail. This has not yet happened for the Great Bear Project.

At this time, I could not find any detailed and professionally certified report on water treatment for proposed exploration and proposed mining. The previous sections of this MDAG review have discussed water treatment as it appeared in some documents, where the current information was found lacking or misleading.

Minewater-treatment plants are not off-the-shelf available at stores like Canadian Tire. This is because their treated effluent concentrations to the environment are very sensitive to the site-specific inflow rate of water and to the inflowing variations in aqueous concentrations of each contaminant element requiring treatment.

These treatment plants can be unstable when exposed to variable flows or to variable inflowing contaminant concentrations, resulting in only partially treated and still-contaminated effluents. Therefore, water treatment for proposed exploration and then again for proposed mining at the Great Bear Project has to be carefully designed, based on well-justified and professionally certified information on surface hydrology, subsurface hydrogeology, ML-ARD, and on-site geochemical source terms.

As shown in the previous sections of this MDAG review, this "input" information into the site-specific and reliable design of water treatment at Great Bear does not exist and will not likely exist for at least a few years. Until then, the available preliminary information is corrupted by errors and missing details. Therefore, it is not possible at this time to reliably define and design the required water treatment at Great Bear, or to estimate effluent concentrations, environmental impacts, and cumulative effects.

To provide some guidance to Grassy Narrows First Nation on aspects of water treatment at the Great Bear Project, it is helpful to review and comment on one of the latest documents that contain some details on possible water treatment. This document is: Great Bear Project Proposed Underground and Open Pit Gold Mine, a PowerPoint presentation made to Asubpeeschoseewagong Netum Anishinabek, dated November 10, 2023

Slide 20 of this presentation is entitled "Water Treatment". It points out that:

> "Contact water discharged to the Chukuni River will be managed to achieve regulatory requirements."

It is important for Grassy Narrows First Nation to recognize that "regulatory requirements" can vary vastly and that the applicable and protective requirements have to be carefully chosen based on site-specific information like flow rates and variations in influent (ML-ARD) and effluent concentrations. Alarmingly, Table 5-6 shown on Slide 20 invokes the "MDMER" or Metal and Diamond Mine Effluent Regulations, which allow toxic levels of metals and other elements. For example, normally toxic levels of 100 ug/L and more are allowed for arsenic and copper, and normally toxic 80 ug/L and more are allowed for lead.

This should be an immediate warning to Grassy Narrows First Nation that Kinross Gold does not intend to treat the site water to safe levels. Instead, treatment will only reduce concentrations to still-toxic levels and then rely on dilution in the Chukuni River to eventually reduce it almost to background levels.

The usage of toxicity dilution in the Chukuni River would create a "mixing zone" for some distance in the river, in which toxicity still exists and for which Fisheries and Oceans Canada would have to authorize the mixing zone. There appears to be some hydrodynamic modelling already done for this mixing zone in the River, but no details like flow rates and their variabilities were provided. Because the previous sections of this MDAG review showed that long-term to perpetual treatment and dilution may be needed for the Great Bear Project, Grassy Narrows First Nation should understand this will represent a very-long-term impact.

Additionally, such long-term ongoing discharge and dilution will add to cumulative effects, about which Grassy Narrows First Nation has expressed serious concerns.

Slides 20 and 21 present additional details on treatment. For example, a special and likely expensive ammonia treatment circuit will be included to treat elevated and toxic ammonia from blasting residues. Remarkably, nitrate and nitrite, which can also be toxic and can stimulate eutrophication in the Chukuni River and Dixie Creek, always accompany ammonia from the blasting residues. However, they are not even recognized here or in other Great Bear documents. This is a serious and unacceptable omission for the Great Bear Project.

Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

Slide 20 also commits to "ultrafiltration" which typically removes all suspended particles coarser than about 0.02 um. Because "dissolved" concentrations include nanoparticles and small particles up to about 0.45 um, this proposed ultrafiltration would also lower the functionally "dissolved" concentrations, but not those of fully dissolved elements. Thus, Great Bear treatment should be capable of approaching CCME (Canadian Council of Ministers of the Environment) safe criteria for aquatic life, but may not meet Grassy Narrows First Nation water-quality criteria (GNFNWQC). CCME aquatic-life guidelines and GNFNWQC could replace the toxic MDMER criteria and significantly reduce or eliminate the mixing zone and cumulative effects in the Chukuni River.

However, none of these details are discussed or mentioned in Great Bear documents.

Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge". In many jurisdictions, treatment sludge like that proposed for the Great Bear Project can reach "hazardous" or "special" waste levels, requiring the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and in sediments including soils and benthic ecosystems.

All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge. This is a major risk for serious environmental impacts that should be addressed in great detail for proposed exploration and proposed mining. I recommend that Grassy Narrows First Nation require intensive studies on the treatment sludge that will remain and be managed somewhere in perpetuity.

In summary for water treatment, Great Bear documents invoke water treatment as the major process that would prevent or minimize environmental impacts of proposed exploration and proposed mining. This is not literally true, because there will be fugitive contaminated water and contaminated dust leaving the site, but this fugitive contamination is ignored or not recognized in many reviewed Great Bear documents.

In any case, water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts, and thus requires intensive study and characterization. However, at this time, water treatment for proposed exploration and proposed mining is ambiguous and contradictory among the documents. This should be expected because the input flows and input contaminant concentrations (ML-ARD) will not be known reliably for at least a few years. Nevertheless, there are serious concerns about water treatment now including the following.

- Kinross Gold does not expect to treat site water to non-toxic levels. Instead, treatment would only be down to still-toxic levels based on the Metal and Diamond Mine Effluent Regulations. Thus, Kinross Gold intends to rely on significant dilution of its contaminated effluent within a "mixing zone" in the Chukuni River. Such a mixing zone would include zones of significant toxicity and would require formal authorization from Fisheries and Oceans Canada. In any case, this discharge of effluent would add to cumulative effects, which is a particular concern of Grassy Narrows First Nation.

- Expensive and intensive treatment for ammonia, derived from blasting residues, is proposed. However, toxic levels of nitrate and nitrite, that always accompany the ammonia and which can cause eutrophication and other impacts in the Chukuni River and Dixie Creek, are completely ignored.

- Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

- Ultrafiltration may substantially reduce effluent concentrations for those elements not fully

dissolved, mixing-zone size, and cumulative effects. However, there are no details on this ultrafiltration in the reviewed Great Bear documents.

- Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge", which can reach "hazardous" and "special" waste levels in some jurisdictions. Thus, treatment sludge requires the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and sediments including soils and benthic ecosystems. All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge that will remain and be managed somewhere in perpetuity.

Riverbank Mercury Methylation Study

Technical Report

May 14, 2024

Submitted by:

Dr. Brian Branfireun, PhD (Professor) Western University

The numerical data presented in this report are validated and certified. The interpretations are based on best available information at this time, and may be subject to change pending further information and expert input.

The opinions expressed in this report are the opinions of the author and should not be represented as the opinions of ANA, the EWRR Panel, or any other party.

Brian Branfireun at London, Canada. May 14, 2024

1 Plain-Language Summary

As part of a larger study of where methylmercury is produced in the Wabigoon River system, a laboratory experiment was done to determine if the water that is discharged from the Dryden Mill to the Wabigoon River makes the methylmercury contamination problem in the Wabigoon River ecosystem worse than it would otherwise be. This water does not contain additional mercury, however it does have high levels **sulphate** and **organic matter**; both are ingredients that are well-known to feed the bacteria that produce methylmercury from inorganic mercury in the environment.

Mercury contaminated sediments were added to small bottles, and water with different chemistries were added to the bottles, including different levels of pure sulphate, and different levels of Mill effluent. Bottles were sampled at different times over a month, and methylmercury and other chemistry was measured in the experimental water.

The results of the experiment showed that when added to mercury contaminated sediments, the Mill effluent containing sulphate and organic matter results in the production of large amounts of methylmercury. At low levels of sulphate, ~50% more methylmercury was produced than with upstream Wabigoon River water that is low in sulphate. At higher levels of sulphate that are like those that are found in the Wabigoon River just downstream of the mill, almost 3 times more methylmercury was formed.

These results clearly indicate that the Dryden Mill industrial wastewater that is discharged to the Wabigoon River is making the mercury contamination in fish worse than it would be if it were not present. The increase in sulphate in the Wabigoon River from the mill source can been seen all the way to Ball Lake, so the impact of this chemistry on methylmercury levels is throughout the river system. Although both mercury and methylmercury levels are very high because of the historical release of mercury to the river in the 1960s which still requires remediation, the problem is amplified by the current mill wastewater discharges. If these discharges were eliminated, there would be a reduction in methylmercury produced in the river system, and a reduction of methylmercury in fish.

3 Introduction

3.1 Project Background and Overview

The overall purpose of this project was to characterize the impacts of elevated sulfate from Dryden Mill effluent on mercury methylation in the English-Wabigoon Rivers System, and evaluate porewater concentrations of Hg, methylmercury and relevant parameters affecting MeHg production (e.g. sulfate, DOC, sulfide, chloride) in the Wabigoon River sediments.

Recent studies have shown that there is significant methylation of mercury in the Wabigoon River downstream of the Dryden Mill (as shown by both the persistent increase in river water methylmercury concentrations, the percent of total mercury as methylmercury, and elevated methylmercury in biota). While there are several factors that could contribute to mercury methylation, one significant question is whether the current Mill wastewater effluent could enhance methylation, amplifying the existing issue of contamination by excess inorganic mercury from historical inputs. Addressing this knowledge gap has been identified as a high priority by EWRRP in the data priorities table: "Evaluation of water quality parameters affecting methylmercury production, e.g., sulphate, DOC, pH, chloride, temperature). Consider an experimental study to identify the contributions of these factors."

It has been established for nearly 40 years that sulphate-reducing bacteria (SRB) are methylators of inorganic mercury[1], and are the principal mercury methylators in freshwater ecosystems[2], responsible for forming the species of mercury that bioaccumulates and biomagnifies (methylmercury). As their name indicates, SRB require sulphate (to 'breathe'), and also organic matter (to 'eat') for their metabolism and growth. The 'respiration' product of sulphate-reduction is sulphide. When SRB are active in an environment where available inorganic mercury is present, the process of mercury methylation can occur within the bacterial cell, resulting in the conversion of inorganic mercury to the more toxic methylmercury. Therefore the mercury methylating activity of SRB is regulated by the supply of three ingredients: organic matter, sulphate and bioavailable inorganic mercury. It is well established that even in environments with background levels of mercury and sulphate, the addition of a sulphate can substantially increase the proportion of mercury that is transformed into methyl mercury in porewater and surface waters[3]; sulphate supply is typically the limiting factor on the mercury methylation process in most freshwater ecosystems under the required biogeochemical conditions. The availability of organic matter is equally important for the mercury methylation process[4]. Although often not limited in an absolute sense, all organic matter is not created equal for

4 Ravichandran, M. **2004**. Interactions between mercury and dissolved organic matter--a review. Chemosphere, 55(3), 319-331.

bacterial metabolism – for example the addition of easily digested dissolved organic matter can be just as important as the addition of sulphate, resulting in the amplification of the sulphate reduction and mercury methylation process[5].

Our prior research (Nearshore Riverbank Sediment and Pore Water Sampling near the Dryden Mill Final Report, 2021) clearly demonstrated that water concentrations of sulphate in the Wabigoon River increased from a mean of 1.61 mg/L upstream of the Dryden Mill to an overall mean of greater than 12 mg/L (with individual samples over 20 mg/L during summer flows) downstream of the continuous discharge of mill aeration stabilization basin (ASB) effluent from a diffuser in the middle of the Wabigoon River (an average increase of about ten times the upstream concentrations). We hypothesized in that report that these elevated sulphate concentrations likely contribute to increased methylation downstream.

3.2 Objectives

This project proposal identified the elevated sulphate concentrations in surface waters as an issue potentially contributing to MeHg production. The work done tested two central hypotheses relating to the role of Dryden Mill effluent discharge on methylmercury formation downstream:

Hypothesis 1: Given that the sulphate-reducing bacteria have been well-established as principle methylators of inorganic mercury in freshwater systems for nearly 40 years, the continuous addition of excess sulphate from the current mill operations in Dryden significantly increases methylmercury formation in this otherwise sulphate-limited environment at both local and more distant locations where conditions suitable for mercury methylation exist.

Hypothesis 2: Low-lying floodplain sediments and wetlands immediately adjacent to the river channel that are contaminated with inorganic mercury are "hot spots" of mercury methylation, with the highest concentrations of methylmercury associated with sediments receiving additional sulphate from upstream.

Information collected will help to understand:

- If the continuous addition of excess sulphate from current Dryden Mill operations significantly increases methyl mercury formation in an otherwise sulphate-limited environment
- If low-lying floodplain sediments and wetlands immediately adjacent to the river are potential hot spots of mercury methylation
- How methylmercury production potential (reflected by % of total mercury as methyl mercury, and partitioning between sediments and porewaters) varies downstream in the English-Wabigoon River System.

This technical report focusses on Hypothesis 1, which was tested using a laboratory approach. Field data associated with Hypothesis 2 will be reported on subsequently.

4 Methods – Sampling & Analysis

4.1 Laboratory Experiment Methods

Previous experiments in the Branfireun Lab have been successful in using glass chromatography columns to test the effects of sulphate addition upon peatland soils, and the current ANA methylation project proposed to use the same general approach. Sediments collected from the mercury contaminated riparian wetland upstream of the effluent discharge were uniformly much finer-grained than anticipated, making the use of a flow through column experiment unfeasible. During preliminary testing, very low hydraulic conductivity (water-passing ability) resulted in a build up of back-pressure in the columns even at flow rates that were minimally feasible to collect sufficient sample volumes in a reasonable time. This created very unrealistic flow conditions, leaks from sample lines, inconsistent flow between columns, and visual channelling of flow along the glass column bypassing sediments. These issues necessitate a change in experimental design and protocol.

A bottle incubation protocol was used to address the question of the effects of different levels sulphate and Mill Effluent containing sulphate on mercury methylation. The experimental treatments were effectively the same as proposed, however instead of columns, Hg contaminated sediments and the various solutions of pure sulphate Mill effluent containing sulphate and were placed in 500ml PETG bottles and destructively sampled over time. Bottle incubations such as this have also been used successfully in the Branfireun lab to assess mercury methylation processes in contaminated sediment.

70 g of sediment collected from a mercury-contaminated wetland downstream of the historic mercury source at the Dryden mill and upstream of the contemporary sulphate source at the operational mill discharge (**Hg concentration 49 mg/kg**), and 70 g of sediment and 140 mL of solution were added to each bottle and allowed to react for between 3 and 28 days. Each bottle was purged with nitrogen gas to expedite the establishment of reducing conditions. and 140 mL of the various solutions (Table 1) were placed in each bottle, mixed, and purged with nitrogen gas to promote reducing conditions. Triplicate samples (3 bottles) were destructively sampled at prescribed intervals (Table 2) from each treatment level on each sampling day, and bottles were gently agitated daily.

Table 2.1. Bottle experiment treatment levels and sample numbers.

Treatment	Description	Number of Samples
Deionized Water – Control	Control – Ultra clean filtered water.	33
Upstream Wabigoon River Water	Control – Unimpacted Wabigoon river water from upstream of the Dryden mill.	33
2 mg/L SO_4^{2-} in Deionized Water	Low Sulphate – Made with pure laboratory reagent (K_2SO_4).	33
10 mg/L SO_4^{2-} in Deionized Water	Medium Sulphate – Made with pure laboratory reagent (K_2SO_4).	33
30 mg/L SO_4^{2-} in Deionized Water	High Sulphate – Made with pure laboratory reagent (K_2SO_4).	33
2 mg/L SO_4^{2-} Effluent Solution	Low Sulphate – Made with diluted effluent collected from the Dryden mill effluent diffuser.	33
10 mg/L SO_4^{2-} Effluent Solution	Medium Sulphate – Made with diluted effluent collected from the Dryden mill effluent diffuser.	33
30 mg/L SO_4^{2-} Effluent Solution	High Sulphate – Made with diluted effluent collected from the Dryden mill effluent diffuser.	33

Table 2.2. Sampling schedule, including reaction time.

Sample #	*Reaction Time*	*Sampling Date*
Sample 1	3 Days	November 26th
Sample 2	4 Days	November 27th
Sample 3	5 Days	November 28th
Sample 4	7 Days	November 30th
Sample 5	9 Days	December 2nd
Sample 6	11 Days	December 4th
Sample 7	14 Days	December 7th
Sample 8	17 Days	December 10th
Sample 9	20 Days	December 13th
Sample 10	24 Days	December 17th
Sample 11	28 Days	December 21st

On each sampling day redox potential were measured directly using a platinum redox electrode in both the supernatant water and the sediment of each bottle. A subsample was taken for sulphide, sulphate and DOC analyses. Supernatant water was centrifuged at 4000 RPM for 20 minutes, filtered with a 0.45 um, then preserved with 0.5% v/v ultrapure HCl prior to analyses for THg and MeHg.

Water samples were analysed for Total Mercury (THg) and Methylmercury (MeHg), SO_4^{2-}, dissolved HS^- DOC, and dissolved organic matter characterization analysis using fluorescence and absorbance spectroscopy.

Benefits of the Bottle Experiment Approach: Although very different from the column experiment, this approach more closely mimicked the interaction of river water with interface sediments. We were also able to measure redox potential directly (not possible with the column experiment). We were also able to recover and measure THg and MeHg in sediment for each sampled bottle, providing a time series in sediment that would not be possible from the column experiment.

4.2 Laboratory Methods

THg and MeHg analyses were conducted in the Biotron Analytical Laboratory at Western University. This is an ISO17025-accredited laboratory and as such, all of the analytical processes that are within its accredited scope comply fully with accepted standard methods. Quality assurance and quality control measures are in place both during the analytical process that meet or exceed the standard methods, and all certified data are reviewed independent of analyses prior to release.

All water samples were filtered through a 0.45 um filter and one aliquot preserved with 0.5% v/v HCl for subsequent analyses for mercury and methylmercury, and another aliquot transferred into pre-cleaned 60 ml amber glass bottles and stored in the dark at 4 °C until analyses for DOC, DOM characteristics, and ions. Sulphide samples were transferred directly into a new, sterile vaccutainer® and analysed immediately.

2.1.1 Total Mercury - Water

Overlying water from the experimental bottles were all analyzed for THg, following EPA method 1631. The day before analysis, samples are brominated. 25 mL of sample is decanted into a glass vial. 125 µL of BrCl is pipetted into each sample vial (including blanks, duplicates, calibration blanks and calibration standards, IPR, and OPR), shaken, and left for analysis the next day. New calibration standards, IPRs, and OPRs are made the day of analysis. Quantification of THg is by CVAFS detection on a Tekran® 2600 total mercury analysis system. Before being loaded into the autosample rack, 30 µL of hydroxylamine hydrochloride and 60 µL of $SnCl_2$ is added to each vial, waiting 30 min between each addition and before analysis. For QA/QC, acceptable recoveries are 71-125% with an RPD < 24% for matrix spikes, < 0.2 ng/L for calibration blanks, < 0.5 ng /L for method blanks, and RPD < 20 % for duplicates.

2.1.2 Methylmercury - Water

Water samples were analyzed for methyl mercury, following EPA method 1630. To analyze MeHg there are two main steps, 1) distilling MeHg out of a sample to eliminate environmental interferences (e.g., organic matter), and 2) quantifying MeHg by aqueous phase ethylation, chromatographic separations, and CVAFS detection in the Tekran® 2700 methylmercury analysis system. 40 mL of sample is poured into a Teflon distillation vessel and capped with a distillation cap. For every 10 samples in the analysis run there is a duplicate sample, a matrix spike sample, a matrix spike duplicate sample, and a method blank. To each prepared Teflon vessel, 180 µL of 1% APDC is added before beginning distillation. Samples are distilled at 125 °C purging with nitrogen gas, in a Tekran distillation unit until 40-48 mL of sample is transferred in the chilled receiving vial.

Following distillation, 30 mL of distilled sample is decanted into a new instrument vial and loaded into the Tekran 2700 sample rack. Reagents (30 µL ascorbic acid, 225 µL buffer solution, 30 µL $NaBet_4$) are added to each sample vial and shaken after each addition to mix thoroughly. Each set of samples includes a set of sample duplicates, matrix spikes, and method blank. For QA/QC, acceptable recoveries are 100 +/- 35% with an < 35% for method spikes, < 0.01 ng/L for reagent blanks, < 0.045 ng CH_3Hg/L for method blanks, and RPD < 35% for duplicates.

2.1.3 Dissolved Organic Carbon

Overlying water in the experimental water samples were analyzed for dissolved organic carbon (DOC) using an OI Analytical Aurora 1030 total organic carbon (TOC) analyser (Xylem, College Station, TX) at the Branfireun Lab, in London, ON. Each run included Milli Q deionized (DI) water blanks, check standards (1 ppm, 5 ppm, 10 ppm, 25 ppm, and 100 ppm) and a sample duplicate at least every 8-10 samples. The minimum detection limit for TOC is 0.01 mg/L C.

2.1.4 Major Anions

Concentrations of target anions (chloride, sulfate) in surface water and porewater samples were analysed using a Dionex® DX-1600 Ion Chromatography System (ICS - Thermo Scientific, Waltham, MA) at the Branfireun Lab. A 0.5 mL aliquot of each pre-filtered sample was dispensed into a sampling vial and a filter cap was placed on top. Each run included two Milli Q deionized (DI) water blanks, matrix spikes, check standards (5 ppm, 10 ppm, and 25 ppm) and a sample duplicate at least every 8-10 samples. If the samples had analyte concentrations outside the range of calibration, they were diluted with Millipore DI water and rerun. The minimum detection limit of the ICS is 0.025 mg/L.

2.1.5 Sulphide

Sulphide analysis was completed immediately during destructive sampling of incubation bottles according to the methylene blue method described in Cline (1969)[6]. 5 mL of supernatant water was extracted under nitrogen and immediately injected into a vacutainer tube to prevent sample oxidation. Each sample reacted with 0.4 mL of a diamene reagent for 20 minutes before measuring absorbance at 670 nm with an integration time of 0.1 s using a Horiba Aqualog spectrofluorometer.

The diamene reagent contains N,N-dimethyl-p-phenylenediamine which reacts with sulphide to form a blue colour. Standard concentration curves were prepared using the same procedure described above, using deoxygenated water and differing concentrations of disodium sulfide nonahydrate.

[6] Cline, J. D. (1969). Spectrophotometric determination of hydrogen sulfide in natural waters. Limnology and Oceanography, 14(3), 454-458.

5 Results & Interpretation: Laboratory Methylation Study

5.1 Reduction-Oxidation Conditions in Experimental Water and Sediment

In the first 5-6 days of the experiment measured redox values indicated that the incubation water in all treatments was still oxic or sub-oxic, which would not support sulphate reduction or Hg methylation (typically at ~ - 200mV) (Figure 1). By Day 7 all treatment waters (including those with no additional sulphate) were strongly anaerobic without significant differentiation and remained so throughout the experiment (Figure 3.1).

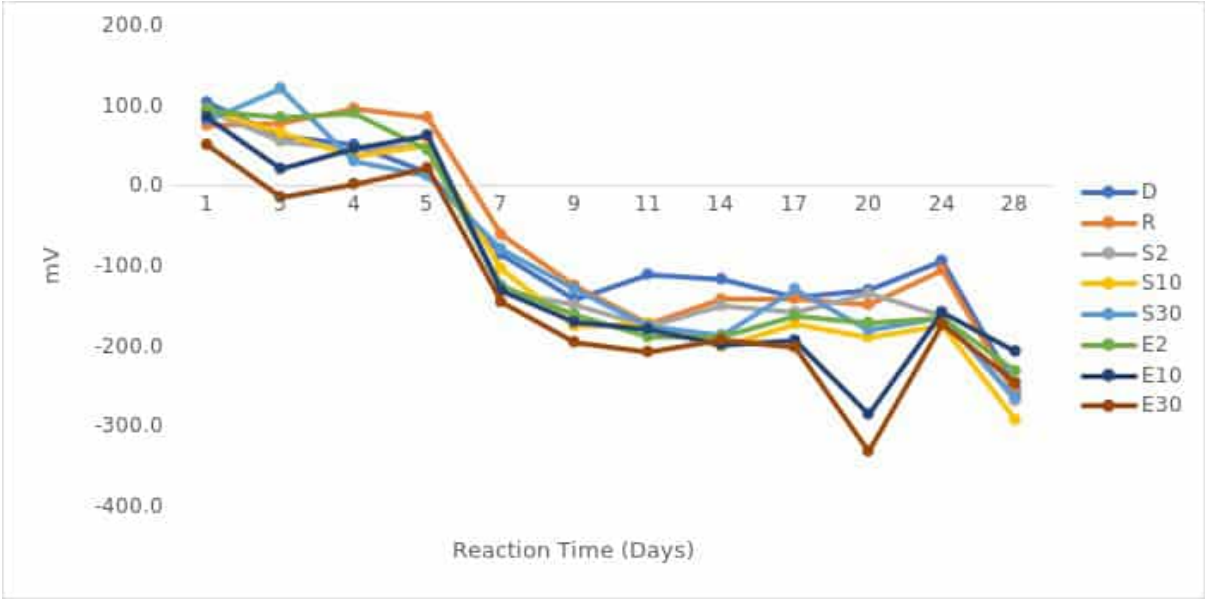

Figure 3.1: Measured redox potential (Eh) in the incubation bottle **water** over the course of the experiment. D = Deionized water. R = Wabigoon River water. S2, S10, S30 = sulphate only treatments at 2, 10 and 30 mg/L.

In contrast, redox potentials in sediments were all sub-oxic at the beginning of the experiment, becoming increasingly negative, settling into deeply anaerobic conditions -200 to -300mV) that would support sulphate reduction and methylation (Figure 3.2).

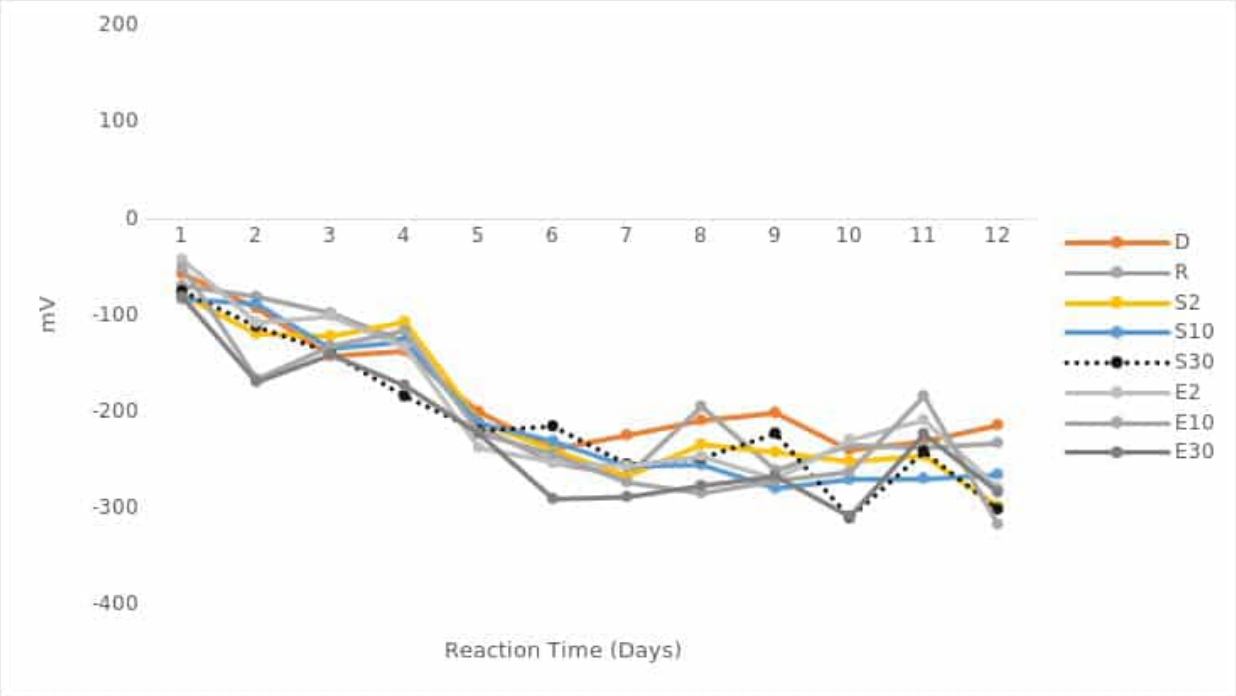

Figure 3.2: Measured redox potential (Eh) in the incubation bottle **sediment** over the course of the experiment. D = Deionized water. R = Wabigoon River water. S2, S10, S30 = sulphate only treatments at 2, 10 and 30 mg/L.

From these data, we can conclude all of the experimental treatments and replicates had suitable biogeochemical conditions to support sulphate reduction and mercury methylation by Day 7 of the incubation.

5.2 Methylmercury Concentrations in Incubation Waters

Methylmercury concentrations in all incubation bottles began clearly increasing at incubation day 7 when the redox potentials in both the sediment and overlying water were sufficiently negative (Figure 3A and 3B). Methylmercury concentrations even increased in the control treatment with only ultra-pure deionized water added, indicating that MeHg was released into overlying water through desorption from the sediments which contained a pre-existing pool of MeHg, or that there was a sufficient amount of oxidized sulphate present in the solid phase or in the field moist sediment to support reasonable rates of Hg methylation (Figure 3.3). The deionized water treatment produced a nearly equivalent amount of MeHg over the course of the incubation, indicating that the additional sulphate found in the Wabigoon River water (1.3 mg/L for the water used in the experiment) had no significant overall impact on MeHg production in this experiment. After Day 9, the average MeHg concentrations were 103.36 and 123.50 ng/L in Deionized water and Wabigoon River water treatments, respectively (Table 3.1).

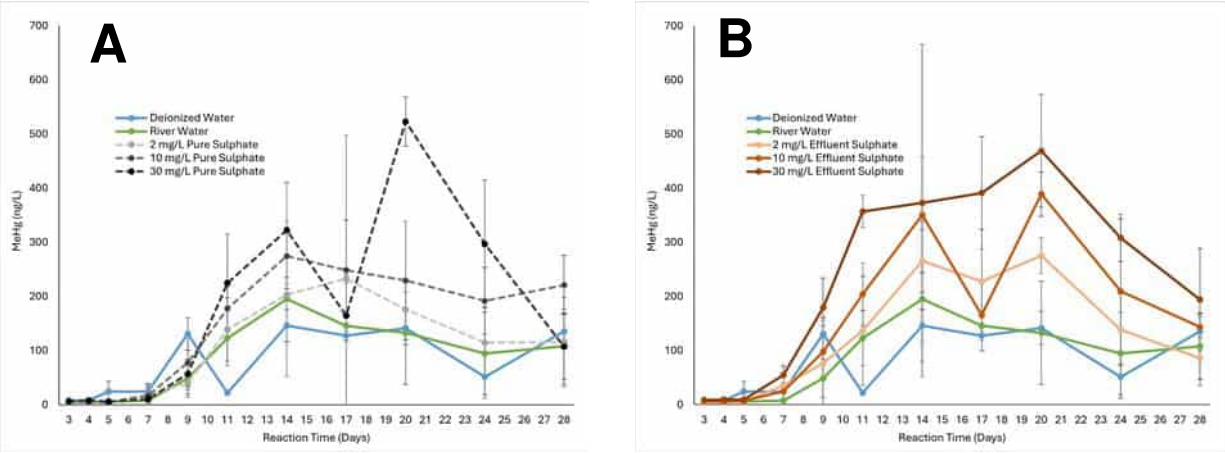

Figure 3.3: Methylmercury (MeHg) concentrations (ng/L) in supernatant water over the duration of the bottle incubation experiment. Sulphate in ultrapure water treatments are presented in Figure 3A, and the sulphate in mill-derived effluent treatments are presented in figure 3B. Deionized water and Wabigoon river water treatments are presented on both panels. Error bars are the standard deviation among replicates.

For the experimental treatments of both sulphate in ultrapure water and mill-derived effluent containing sulphate, average MeHg concentrations exhibited a pattern of clear increase between day 7-11, a stabilization until day 20-22, then some evidence of decline. This pattern is what would be expected in a microbial incubation, where bacteria have both nutrients and organic matter to increase their population and activity (exponential growth phase), and then maintain metabolism with available resources (stationary phase) until a required metabolite becomes limiting or the environment toxic. Since no additional nutrients (sulphate) or organic matter was added to the experiment, it was expected that at some point the experimental conditions would become unfavourable for bacterial metabolism. This would not occur in the natural environment where nutrient supply and organic matter inputs are replenished from advective water flows, plant roots, soil biota, etc. The achievement of stationary phase allows us to examine differences among experimental treatments under these (relatively) more stable conditions (i.e. between days 9 and 24 of the experiment).

Methylmercury concentrations increased in all of the sulphate addition treatments, with higher MeHg concentrations associated with the higher sulphate additions. MeHg concentration increases were not proportional with sulphate concentrations (i.e. they do not increase proportionally to the same degree) but are still in increasing order with treatment level (Table 5.1). Relative to Wabigoon River water with sulphate concentrations of 1.3 mg/L, it is consistent that the 2 mg/L pure sulphate treatment would result in slightly higher concentrations. Indeed, MeHg concentrations are 22% higher, in line with the 53% higher sulphate amount and the overall sub-linear response (Table 5.2). The relative percent difference between Wabigoon River water and the 2 mg/L mill effluent sulphate treatment was over twice as great as for the pure sulphate treatment alone (51% vs 22 %) indicating a dramatic and important additive effect of the Dryden Mill effluent chemistry.

Table 3.1. Average methylmercury (MeHg) concentrations (ng/L) measured in supernatant water from experimental samples during stationary phase of bottle incubation (Day 9-24).

Treatment Level	Average MeHg in Supernatant Water (ng/L)
Deionized Water	103.36
Upstream Wabigoon River Water	123.50
2 mg/L Pure Sulphate	151.01
10 mg/L Pure Sulphate	200.04
30mg/L Pure Sulphate	264.96
2 mg/L Mill Effluent Sulphate	186.80
10 mg/L Mill Effluent Sulphate	236.29
30mg/L Mill Effluent Sulphate	346.52

Table 3.1. % difference in methylmercury concentrations of experimental treatments relative to deionized water control and Wabigoon River water (1.3 mg/L sulphate) during the stationary phase of bottle incubation (Day 9-24).

Treatment Level	Increase in MeHg (%) above Deionized Water	Increase in MeHg (%) above Upstream Wabigoon River Water
2 mg/L Pure Sulphate	46%	22%
10 mg/L Pure Sulphate	94%	62%
30mg/L Pure Sulphate	156%	115%
2 mg/L Mill Effluent Sulphate	81%	51%
10 mg/L Mill Effluent Sulphate	129%	91%
30mg/L Mill Effluent Sulphate	235%	181%

This relative enhancement of Hg methylation by mill effluent over pure sulphate was clear for all treatments. At the highest levels of sulphate addition (30 mg/L), the mill effluent treated bottles had MeHg concentrations that were 2.8 times greater the Wabigoon River water treatment, and 3.4 times greater than the deionized water treatment. Even at the lowest level 2 mg/L sulphate treatment in mill effluent, these increases were 1.5 and 1.8 times greater, respectively. It is clear that the addition of mill effluent (which at the discharge point after mixing with river water can routinely exceed 50 mg/L) substantially enhanced MeHg production in the laboratory experiment. The addition of sulphate increased MeHg production consistent with pre-existing scientific knowledge; the additive effect of the other mill effluent chemistry on MeHg production paints an alarming picture for the conditions in the English-Wabigoon River system, where increases in sulphate and dissolved organic matter due to the mill discharges are evident as far down as data clearly exist (Ball Lake outflow, and potentially beyond).

5.3 Total Mercury and Percent of Total Mercury as Methylmercury

It would be expected that THg in overlying water in the bottle experiments would increase for two reasons: 1) Thg comprises all forms of mercury, and therefore contains BOTH inorganic Hg and MeHg. Since MeHg increased substantially in the experimental treatments, and we may reason that this MeHg was derived from sediment pore waters, then THg would increase at least proportionally to that increase in MeHg. 2) We may also expect the fraction of THg as IHg to increase given the level of Hg contamination in the experimental sediments. Given the concentration difference, there would be diffusion of IHg from sediment porewaters to the overlying waters due to the concentration gradient.

Consistent with this, changes in THg concentrations over time (Figure 3.4) mirrored the changes in concentrations in MeHg (Figure 3.3). The pattern over time and the relative magnitude of changes (increases) mirrored those of MeHg largely because a substantial fraction of THg in the overlying water was MeHg (Figure 3.5).

During the stationary phase of the experiment. the overall differences %MeHg generally fall in line with the relative amounts of sulphate added (30>10>2 mg/L) (Figure 3.5). The sulphate source (Mill Effluent Sulphate vs. pure Sulphate) trends were less differentiated, however all treatments subjected to Mill Effluent had more consistent, and higher %MeHg. During the stationary phase of the experiment, all Mill Effluent sulphate treatments had >60% MeHg; a very high fraction given that there is no fresh inputs of either sulphate or organic matter.

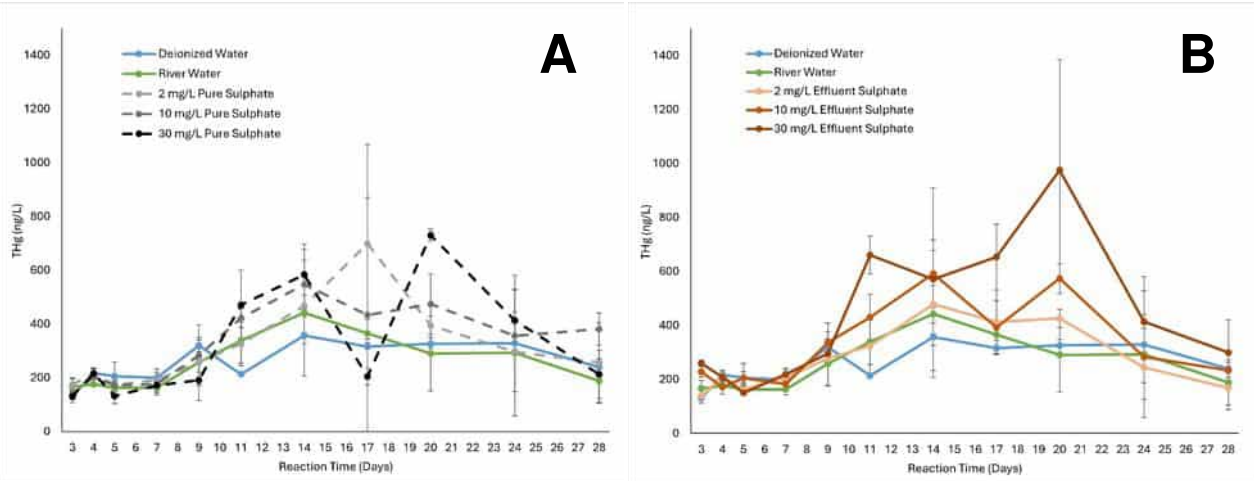

Figure 3.4: Total Mercury (THg) concentrations (ng/L)
in supernatant water over the duration of the bottle incubation experiment. Sulphate in ultrapure water treatments are presented in Figure 3A, and the sulphate in mill-derived effluent treatments are presented in figure 3B. Deionized water and Wabigoon river water treatments are presented on both panels. Error bars are the standard deviation among replicates.

The inorganic fraction of THg (IHg, calculated at THg – MeHg) showed an almost immediate partitioning of a substantial amount of IHg from sediment and sediment pore waters to the overlying water (Figure 3.6). Given that the deionized water treatment had no measurable Hg of any form, this partitioning was not only rapid, it remained relatively constant over time and across treatments suggesting that there was no other biogeochemical factor other than concentration difference that was driving the transfer of IHg into overlying water. This finding is relevant, because it revealed that the exchange of "clean" water with contaminated sediments resulted in the rapid partitioning of 100s of ng/L of IHg into overlying water in the bottle experiments; concentrations that are 2 orders of magnitude above background Wabigoon River water concentrations. Although not an explicit objective of this experiment, it demonstrates that the Hg in legacy contaminated sediments in the English-Wabigoon system is easily partitioned into pore waters and surface waters.

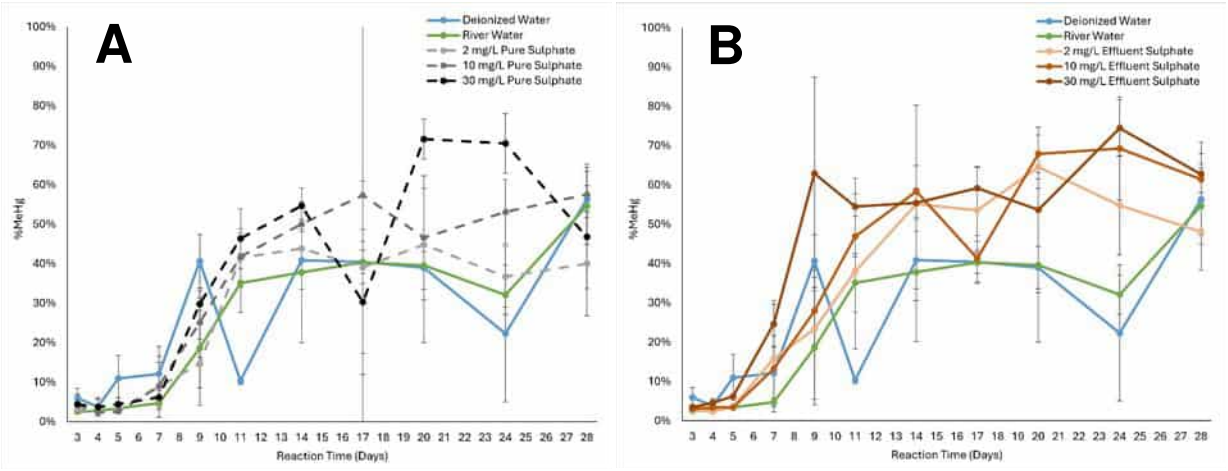

Figure 3.5: Percent of Total Mercury as Methylmercury (%MeHg) in supernatant water over the duration of the bottle incubation experiment. Sulphate in ultrapure water treatments are presented in Figure 3A, and the sulphate in mill-derived effluent treatments are presented in figure 3B. Deionized water and Wabigoon river water treatments are presented on both panels. Error bars are the standard deviation among replicates.

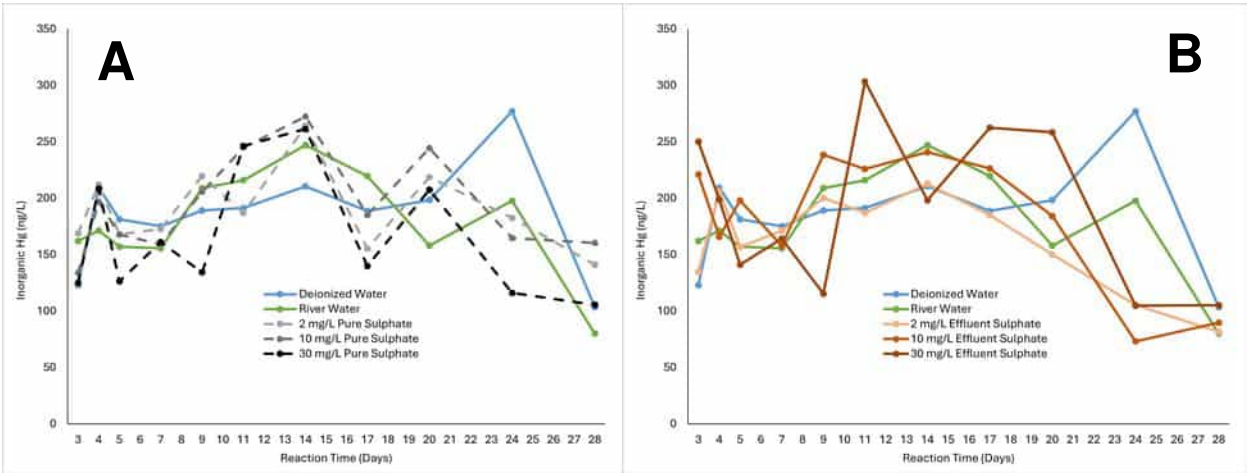

Figure 3.6: Inorganic mercury (IHg) in supernatant water over the duration of the bottle incubation experiment. Sulphate in ultrapure water treatments are presented in Figure 3A, and the sulphate in mill-derived effluent treatments are presented in figure 3B. Deionized water and Wabigoon river water treatments are presented on both panels. **Error bars to be added to this figure**

5.4 Sulphide Concentrations in Incubation Waters

Dissolved sulphide concentrations unsurprisingly increased in all of the incubation flasks, indicating that active sulphate reduction was occurring in all bottles, including the deionized water treatments (Figure 3.7). Since no additional sulphate was associated with these 'controls' it is clear that there was sufficient available sulphur in the incubation sediments to support Hg methylation and produce the MeHg concentrations measured (Figure 3.3).

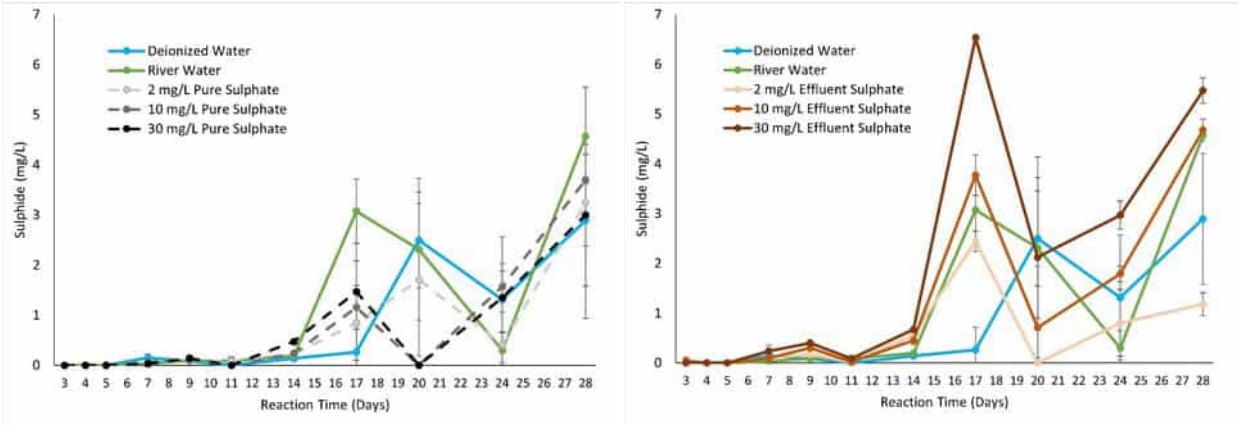

Figure 3.7: Dissolved sulphide (S^-) in supernatant water over the duration of the bottle incubation experiment. Sulphate in ultrapure water treatments are presented in Figure 3A, and the sulphate in mill-derived effluent treatments are presented in figure 3B. Deionized water and Wabigoon river water treatments are presented on both panels. Error bars are the standard deviation among replicates.

Dissolved sulphide concentrations in the experimental treatments did NOT correspond with sulphate addition levels, which indicates that at the highest sulphate concentrations there is likely the formation of precipitated insoluble S^- complexes, and/or an inhibition of sulphate reduction by sulphide toxicity. Indeed in the pure sulphate treatments, the sulphate addition treatments were no different, or even lower than the deionized water and Wabigoon River water treatments. In contrast, the provision of additional sulphate in Mill Effluent generally produced more sulphide than an equivalent treatment of pure sulphate, indicating that the sulphate reduction process was intensified by the Mill Effluent chemistry, or that sulphide was maintained in solution to a greater degree because of differences in water chemistry. **It is my opinion that the former is more likely, and that the provision of both sulphide and bioavailable organic matter in the Mill Effluent intensifies the activity of sulphate reducers (as indicated by the concentration of the sulphide product) and thus produces more MeHg (as indicated by the absolute concentration of MeHg, and the relative difference in %MeHg).** During the stationary phase, there is a clear, positive relationship between MeHg and S^- ($r^2 = 0.32$) confirming that sulphate reduction/active mercury methylation is driving the release of MeHg into overlying waters, not desorption from an existing pool of MeHg in sediments.

6 EXPERIMENTAL LIMITATIONS AND APPLICATION TO FIELD CONDITIONS

As a bottle incubation with destructive sampling of separate replicate samples at each time interval, there was considerable and expected variability among replicates, and between sampling times. Despite homogenization of sediments used for the experiment, the relatively small amounts placed in each bottle have variable amounts of organic matter, mercury contamination, and even biological activity. Rather than compromising the interpretation of the results, the fact that the experimental treatments resulted in clear patterns *despite* this variability lends confidence that the mechanisms (and magnitudes of effect) are real.

The sulphate (and diluted effluent) added to the experimental bottles was only a single 'dose' at the beginning of the experiment. This dose was metabolized by the bacterial community over the duration of the experiment until the replicate was sampled, and was not replenished. Therefore the amount of sulphate added (and the designation given to each treatment) is merely the initial amount, which would decline over time until such time that it was completely metabolized. Under field conditions, not only would the supply of sulphate (and organic matter) be effectively continuous to the sediment-water interface and hydrologically-connected riverbank locations, but sulphide would also be transported away, reducing the potential for sulphide toxicity which would limit sulphate reduction rates. Therefore under field conditions in locations where suitable biogeochemical conditions exist, methylmercury production would be more continuous and potentially less rate limited. In locations that are subjected to more episodic flooding, the dose-response pattern may be more similar to what was observed in this experiment.

The sediments used in this experiment (from Wetland 1 immediately downstream of the Mill but upstream of the mill effluent diffuser were lower in organic matter content relative to other wetland sites that were sampled as part of this project; riparian wetlands with higher natural organic matter content in sediments would likely support higher rates of Hg methylation.

7 CONCLUSIONS

The results of the laboratory incubation experiment component of this project showed that:

1) the addition of water with even small amounts of additional sulphate increases the net production of methylmercury in mercury-contaminated river bank sediments.

2) the amount of methylmercury produced is positively related to the amount of sulphate added, but the increase in methylmercury production is not proportional (i.e. double the sulphate does not produce double the methylmercury).

3) Sulphate added as a component of Mill Effluent resulted in approximately double methylmercury being produced than just sulphate alone. Data from this experiment suggests that this is a result of greater activity/growth of sulphate-reducing bacteria, which are the primary methylators of inorganic mercury in freshwater systems. The mechanism of this enhanced microbial activity is the provision of bioavailable organic matter in the Mill Effluent water.

We can extend these clear results to the English-Wabigoon River system, and draw several broader conclusions that have important implications for the recovery of mercury contamination in fish:

4) The experimental results clearly support Hypothesis 1: *The continuous addition of excess sulphate from the current mill operations in Dryden significantly increases methylmercury formation in this otherwise sulphate-limited environment at both local and more distant locations where conditions suitable for mercury methylation exist.* The large increase in sulphate and organic matter above Wabigoon River background levels by past and current Dryden mill operations amplifies the methylation of mercury in contaminated sediments throughout the English-Wabigoon River system. Even considering the effects of dilution, this effect extends as far as the sulphate input from the Mill can be detected (at least to Ball Lake outflow) since the data from this experiment show that even small increases in sulphate above background levels increased methylmercury production.

5) Given the record of sulphate concentration data from the Wabigoon River and the results of this experiment, there is likely *at least* twice as much methylmercury being produced than would be expected under background sulphate and organic matter conditions. Given that the amount of methylmercury in fish is ultimately proportional to the amount of methylmercury available to biota, fish methylmercury is likely at least twice as high as would be expected under background sulphate and organic matter conditions.

6) The elimination of excess industrial sulphate and organic matter inputs to the Wabigoon River from the Dryden Mill would reduce the amount of methylmercury produced throughout the English-Wabigoon system, and reduce methylmercury in

aquatic organisms and fish. Based on published scientific literature, the reduction in methylmercury concentrations in water and biota could be relatively rapid (several years).

7) Since sediments are still highly mercury contaminated and there will always be background levels of methylmercury production, the amount of methylmercury present will still be well above what would be expected under uncontaminated conditions even when industrial sulphate and organic matter inputs are eliminated. Ultimately a reduction in the pool of available inorganic mercury for methylation is required to return the ecosystem to levels of mercury in fish that would be present without past and present mill impacts.

EQUITY. JUSTICE. HEALTH.

June 17, 2024 **BY EMAIL**

The Hon. Steven Guilbeault
Minister of Environment and Climate Change
200 Sacré-Coeur Boulevard
Gatineau QC K1A 0H3

Dear Minister Guilbeault:

RE: IMPACT ASSESSMENT OF GREAT BEAR GOLD PROJECT – REFERRAL TO REVIEW PANEL [REFERENCE NUMBER 85832]

Please be advised that we are co-counsel for Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows First Nation") in relation to the above-noted designated project.

On behalf of ANA, we hereby request that you refer the impact assessment of the Great Bear Gold Project to a review panel pursuant to section 36 of the *Impact Assessment Act* (*IAA*). This review panel should be an independent panel composed of experts and respected people mutually agreeable to ANA and Canada.

For the reasons set out below, our client's requested referral of the impact assessment to a review panel is in the public interest, facilitates protection of ANA's Aboriginal, treaty, and inherent rights, and supports ensuring that the adverse effects of the project upon matters of federal jurisdiction will be assessed, mitigated and prevented in a more credible, participatory, and accountable manner.

Please be advised that ANA's preliminary comments on the draft Tailored Impact Statement Guidelines and the proposed Indigenous Engagement and Partnership Plan for this project have been provided to the Impact Assessment Agency of Canada ("Agency") under separate cover.

Please note that ANA does not consent to the Great Bear Gold Project and ANA reserves the right to file further submissions regarding this referral request as additional information, new documentation and/or technical capacity becomes available to ANA.

This request for Ministerial referral to a review panel should be read in conjunction with all the previous comments, letters, and other communications sent from ANA to your Ministry and/or the Impact Assessment Agency of Canada to date, including expert reports by Dr. Carignan, Dr. Podur, Dr. Mergler, Dr. Willow, Dr. Morin, Dr. Branfireun and the reports and scientific literature on mercury and Grassy Narrows that have been shared with Crown or are publicly available.

Canadian Environmental Law Association
T 416 960-2284 • 1-844-755-1420 • F 416 960-9392 • 55 University Avenue, Suite 1500 Toronto, Ontario M5J 2H7 • cela.ca

BACKGROUND

As noted in ANA's letter to the Agency, proponent, and Ontario government dated March 6, 2024 (attached), our client remains deeply concerned about, and continues to strongly object to, this proposed project.

The overall context for ANA's opposition to the Great Bear Gold Project is provided by the significant adverse environmental, socio-economic, and human health impacts that the ANA community has suffered – and still suffers – due to industrial resource-based activities undertaken in, around, and upstream of our client's territory without ANA consent, meaningful consultation and accommodation with ANA, and often without prior notice to ANA.

The ANA letter also states that the designated project, if approved, would be sited within ANA's traditional use area and cause adverse impacts to the local environment, water quality, fish and wildlife, species at risk, migratory birds, and the downstream ANA community:

> The Great Bear Gold Project falls within the area that Grassy Narrows people have historically and currently use for the exercise of our rights and way of life. It is also upstream from our community. Pollutants in the water and impacts on the surrounding land, fish and wildlife will have a direct impact upon us and could also exacerbate mercury contamination in our waterways.
>
> ANA has repeatedly and clearly communicated with the Crown and the mining industry that our people are in crisis, the environment which supports us is severely impacted, our health is failing. The cumulative impacts continue to significantly interfere with our treaty, Aboriginal and inherent rights.
>
> The Great Bear Gold Project will have an impact upon areas that Canada claims as within federal jurisdiction, such as species at risk, fisheries, waterways and Indigenous peoples (page 2).

Notably, the proponent's Detailed Project Description (January 2024) indicates that the following factors were used to identify Indigenous communities that should be engaged in the impact assessment process:

- Proximity to the Project, including known historic and current Indigenous traditional land use and occupation, location of Reserve lands
- Potential for their interest to be affected Project activities
- Past or current interest in similar projects or developments in the region
- Guidance from government agencies, such as the provincial Ministry of Mines(page 9) .

Applying these factors in this case, the Detailed Project Description correctly lists ANA as an Indigenous community to be engaged in the assessment process since ANA is interested in, or may

be "materially affected" by, the Great Bear Gold Project (page 9). Accordingly, ANA has the requisite standing and constitutionally protected rights to request referral of the impact assessment to a review panel under the *IAA*. Notably, ANA is the first community downstream of the project site, and is already subject to extreme cumulative impacts, and therefore ANA is acutely, and uniquely, at risk from this Project.

REASONS FOR REFERRAL TO REVIEW PANEL

(i) The *IAA* Test for Referral to a Review Panel

Section 36(1) of the *IAA* empowers you to refer an impact assessment to a review panel if you opine that it is in the public interest to do so. This referral must generally occur no later than 45 days after the Notice of Commencement of an impact assessment has been posted online.

Section 36(2) of the *IAA* outlines the mandatory factors to be considered when making the public interest determination about referring an impact assessment to a review panel:

> **36(2).** The Minister's determination regarding whether the referral of the impact assessment of the designated project to a review panel is in the public interest must include a consideration of the following factors:
>
> (a) the extent to which the effects within federal jurisdiction or the direct or incidental effects that the carrying out of the designated project may cause are adverse;
>
> (b) public concerns related to those effects;
>
> (c) opportunities for cooperation with any jurisdiction that has powers, duties or functions in relation to an assessment of the environmental effects of the designated project or any part of it; and
>
> (d) any adverse impact that the designated project may have on the rights of the Indigenous peoples of Canada recognized and affirmed by section 35 of the *Constitution Act, 1982*.

We are aware that the federal government has recently proposed various amendments to the *IAA* in response to the 2023 ruling by the Supreme Court of Canada that aspects of the legislation are unconstitutional for division-of-powers reasons.

However, aside from some minor changes in certain upfront definitions (e.g., "adverse effects within federal jurisdiction" and "direct or incidental adverse effects"), no specific amendments have been proposed to date in relation to your statutory discretion under section 36 of the *IAA*. Therefore, your referral authority under this provision remains fully intact and should be exercised in this case, as discussed below.

(ii) Applying the *IAA* Test to the Great Bear Gold Project

For the purposes of this referral request, ANA's submissions focus on three public interest factors listed in section 36(2)(a), (c) and (d) of the *IAA*.

Adverse Effects on Matters of Federal Jurisdiction

The current *IAA* definition of "effects within federal jurisdiction" is generally limited to fisheries, aquatic species at risk, migratory birds, and Indigenous physical/cultural heritage, Indigenous land/resource uses for traditional purposes, Indigenous structures/sites of historical/archaeological significance, and changes to the health, social or economic interests of the Indigenous peoples of Canada (section 2 of the *IAA*). The proposed amendment to this definition presently being considered by Parliament essentially repeats the same listed items but inserts the qualifier that these effects must be "adverse", which is further defined as a "non-negligible adverse change."

Regardless of whether the current or amended definition is applied in this case, it is indisputable that the Great Bear Gold Project, if approved, has considerable potential to cause significant (non-negligible) adverse impacts upon most or all the above-noted items within federal jurisdiction.

For example, as noted in the attached ANA letter, the Great Bear Gold Project site falls within Grassy Narrows' Interim Area of Interest for Mining. Accordingly, the project will likely cause negative impacts on the lands and resources (e.g. moose, caribou, wolverine, walleye, wild rice, medicines, etc.) which were traditionally used – and are still being used today – by ANA members for hunting, fishing, trapping, and other harvesting activities or spiritual practices in the vicinity of the project and generally throughout the English River watershed.

ANA is also concerned that the proposed forest/vegetation clearing, other destructive disturbances, and industrial-scale activities associated with the project (e.g., surface water takings, aquifer de-watering, wastewater discharges, waste rock and tailings storage, etc.) may cause localized and downstream water pollution problems and exacerbate the well-documented health impacts of the mercury and methylmercury known to be present in the watercourses (and bioaccumulating in fish) within ANA territory. This is particularly true because sulfate will be present in wastewater discharges, which leads to an increase in mercury methylation in the receiving bodies of water.

Similarly, ANA is alarmed by the potential adverse impacts on groundwater, surface water, and aquatic ecosystems arising from metal leaching and acidic drainage from the 1 million tonnes of waste rock that will be excavated during advance exploration and stored in perpetuity on-site either above-ground or below-ground, and by the far larger mass of tailings that will be generated during mining and stored on-site in perpetuity if the project is approved.

ANA's preliminary submission to the Impact Assessment Agency of Canada about this project elaborates in greater detail on the likely adverse impacts in areas of federal jurisdiction from this Project including on species at risk and on the rights, health, wellbeing, and livelihood of Grassy Narrows people.

By any objective standard, these and other effects upon matters of federal jurisdiction are profound, significant and deleterious in nature. Accordingly, ANA submits that it is imperative to ensure that such impacts are properly identified and assessed in an open, accessible and rigorous manner, which is best achieved by referring the impact assessment to a review panel.

Opportunities for Inter-Jurisdictional Cooperation

Ontario's *Environmental Assessment Act* (*EAA*) does not automatically apply to mining projects in the province. In addition, the Ontario government has taken no steps to date to designate the Great Bear Gold Project as an undertaking that requires a Comprehensive EA under Part II.3 of the *EAA*.

Accordingly, referral of the impact assessment to a review panel in this case poses no constraints on, and has no negative implications for, inter-jurisdictional cooperation with Ontario for the purposes of evaluating impacts under the *IAA* and *EAA*. For example, since the Great Bear Gold Project is not currently subject to Part II.3 of the *EAA*, there is no opportunity for ANA to request that the matter be referred to the Ontario Land Tribunal for a public hearing and decision.

However, if Ontario decides to designate the Great Bear Gold Project, then referral to a review panel under the *IAA* preserves the opportunity to integrate the two assessments pursuant to the joint review panel provisions of the *IAA* (section 39) and the harmonization provisions of the *EAA* (section 3.1) to ensure that risks of adverse impacts to all relevant areas of purported federal and provincial jurisdiction are assessed comprehensively in a holistic and participatory manner.

ANA also notes that the Great Bear Gold Project requires various provincial permits, licences, and approvals (e.g., Permit to Take Water, Environmental Compliance Approval (Sewage), etc.., However, none of these permits considers the Project as whole in its full context, which further illustrates the need for inter-jurisdictional coordination and cooperation between the federal and provincial governments.

Adverse Effects on Section 35 Rights

As described in the attached ANA letter, ANA is an Anishinaabe First Nation with traditional territory in what is now called northwestern Ontario and the ANA people have cared for and lived on these lands for countless generations.

As noted above, ANA people hunt, trap, fish and practice their Anishinaabe way of life throughout this territory to provide for themselves, their families and their community. This territory is the foundation of who Grassy Narrows people are as Anishinaabe people, who follow the teachings of the Elders to be responsible for the territory and to *Manaachitootaa Aki* (protect the land).

The ANA community has an inherent right to self-determination and law-making powers, as conferred upon ANA by the Creator. In addition to these inherent rights, ANA exercises Aboriginal rights and established Treaty 3 rights which are protected by section 35 of the *Constitution Act, 1982*.

In 1873, the Anishinaabe adhered to Treaty 3. The Treaty 3 Commissioner promised the Anishinaabe that the Treaty would protect their harvesting practices forever, which would allow ANA people to hunt, fish, trap, gather, and harvest throughout the Territory as they had before "as long as the sun shone and the waters flowed." At no time did the Anishinaabe agree to the erosion, impairment. or termination of their harvesting rights within the traditional territory beyond the Dawson route.

Accordingly, the attached ANA letter states that the intrusive, large-scale, and complex nature of the Great Bear Gold Project poses sizeable risks to, and impacts upon, the community's Treaty 3 rights:

> The Great Bear Gold project is a massive one, with great risks to Grassy Narrows and that can have a major impact on many aspects of Grassy Narrows' relationship with the Crown including our Treaty, the honour of the Crown, fiduciary duties, outstanding obligations, unmet duties, and reconciliation.

In these circumstances, referral of the impact assessment to a review panel will provide an important forum for ANA to pursue and present their concerns, lay and opinion evidence, and communal perspectives on the project's impacts on Aboriginal, treaty, and inherent rights.

Granting ANA's requested referral would also be consistent with the current *IAA* preamble and the federal government's mandate under section 6 of the *IAA* (and the proposed amendments thereto) which invoke the *United Nations Declaration of the Rights of Indigenous Peoples*, require respect for Aboriginal/treaty rights recognized and affirmed by section 35 of the *Constitution Act, 1982*, and emphasize reconciliation with the Indigenous peoples of Canada.

ANA hastens to add that the referral to a review panel does not, in and of itself, remedy the continuing failure of the Crown to meaningfully notify, consult, and accommodate ANA, and gain ANA's free, prior, and informed consent, in relation to the Great Bear Gold Project.

On this point, ANA maintains its position that honourable, sincere and timely government-to-government engagement must occur in relation to the Great Bear Gold Project (including the threshold question of whether the project can proceed at all). Moreover, the Crown's duty to consult cannot be delegated to the proponent in the impact assessment process, regardless of whether the ANA referral request is granted.

Part of the mandate of the review panel should be assess and to make recommendations to the Minister on whether, or not, ANA's free, prior, and informed consent for the project has been obtained and on whether allowing the project to proceed would be consistent with the *United Nations Declarations of the Rights of Indigenous Peoples*.

(iii) Past Practice regarding Referral of Mining Projects

Under the *IAA* and its predecessor legislation (i.e., *Canadian Environmental Assessment Act, 2012* and *Canadian Environmental Assessment Act, 1992*), there are several precedents where

assessments of mining projects throughout Canada have been referred to independent review panels, including the following proposed mines:

- Marathon Platinum Group Metals and Copper Mine Project (Ontario)
- Suncor Base Mine Extension Project (Alberta)
- Rose Lithium – Tantalum Mine Project and the James Bay Lithium Mine Project (Quebec)
- Grassy Mountain Coal Project (Alberta)
- Robb Trend Coal Mine Expansion Project (Alberta)
- Frontier Oil Sands Mine Project (Alberta)
- Jackpine Mine Expansion Project (Alberta)
- Pierre River Mine Project (Alberta)
- Prosperity Gold-Copper Mine Project (British Columbia)

Given the well-documented adverse environmental effects of major mine projects, this referral track record is reasonable, intelligible, and justifiable to ensure that robust assessments of mining impacts on areas of federal jurisdiction are carried out by review panels.

In relation to the above-noted Marathon mining project in northwestern Ontario, ANA notes that the proposal referred to the review panel in that case included three open pits, an ore processing plant, tailings and mine rock storage facilities, site access roads, a power transmission line, explosives factory and magazines, water management facilities, ancillary mine infrastructure, associated activities, and an estimated lifespan of 11.5 years.

In comparison, as indicated in the Detailed Project Description (pages 15 to 29), the components of the Great Bear Gold Project are substantially similar to the Marathon proposal in terms of size, scale, infrastructure, and potential environmental impacts. However, the Great Bear Gold Project includes not only three new open pits but also features an underground mine, storage of 1 million tonnes of waste rock arising from advanced exploration, extensive water-takings from surface water and groundwater resources, discharges of treated effluent to the Chukuni River, and an overall lifespan of approximately 25 years. In additions the Great Bear Gold Project is proposed to take place in an area with extreme pre-existing, current, and planned cumulative impacts to land and water from industrial activities which have resulted in horrific and well-documented impacts to the health and wellbeing of Grassy Narrows people. If the Marathon mine project warranted a review panel referral, then the Great Bear Gold Project clearly does as well for the site-specific reasons outlined above.

More generally, ANA notes that Ministerial decisions to refer mining and non-mining projects to review panel hearings have been typically based on various considerations, including: (a) potential adverse environmental effects to fish and fish habitat, aquatic species at risk, and migratory birds, (b) potential impacts on the rights of Indigenous peoples; (c) general public concern; and (d) the opportunity to cooperate with provincial governments. In ANA's view, these considerations are directly relevant and fully applicable in relation to the Great Bear Gold Project.

The plight of Grassy Narrows, and the threat of additional impacts to Grassy Narrows from mining activities, are one of the most notorious matters of general public concern in Canada as evidenced by the hundreds of prominent news media reports and thousands of public letters addressing this matter in recent years. Accordingly, there is no compelling policy reason or evidence-based rationale to depart from the well-established federal practice of referring mining project impact assessments to review panel hearings. Indeed, the Great Bear Gold Project is at least as worthy, if not more, of a review panel hearing, than the precedent projects listed above.

(iv) Public Interest Benefits of Referral to a Review Panel

At present, the forthcoming impact assessment of the Great Bear Gold Project will be conducted by the Agency unless the matter is referred to a review panel.

With all due respect to the Agency's institutional experience in environmental assessment, ANA submits that it would be preferable, from the public interest perspective, to appoint and empower an independent review panel in relation to the Great Bear Gold Project.

First, as a matter of law, the members appointed to the review panel must be "unbiased and free from any conflict of interest relative to the designated project" and must "have knowledge or experience relevant to the designated project's anticipated effects or have knowledge of the interests and concerns of the Indigenous peoples of Canada that are relevant to the assessment" (section 41 of the *IAA*, emphasis added). These important qualifications do not expressly apply to Agency officials conducting impact assessments (see sections 153 to 165 of the *IAA*). All of Canada will be watching this impact assessment process, and the persons carrying out this impact assessment must be, and must be universally perceived to be, unbiased and expert in the relevant subject matter.

Second, review panels are obligated under the *IAA* to hold public hearings that offer "the public an opportunity to participate meaningfully, in the manner that the review panel considers appropriate and within the time period that it specifies, in the impact assessment" (section 51(1)(c) of the *IAA*). The public hearings held by review panels may be flexible or informal, but they must be generally consistent with "the rules of procedural fairness and natural justice" (section 54 of the *IAA*). Again, this latter statutory provision does not expressly apply to Agency-led impact assessments.

Third, the public hearings held by review panels provide more extensive participatory opportunities for Indigenous communities such as ANA to present factual, technical and scientific evidence about the designated project and the factors listed in section 22 of the *IAA*. Similarly, review panel hearings enable Indigenous communities such as ANA to test or respond to the

evidence offered by proponents and government ministries or agencies in relation to the impact assessment. As correctly noted by a leading commentator:

> The most important opportunity for public involvement in federal environmental assessment is a panel review triggered by the Minister of Environment.[1]

Fourth, the hearing process (including full public disclosure of information, ability to summons witnesses, etc.) will greatly assist in ensuring the accuracy, reliability. and soundness of the review panel's report to the Minister (section 51(1)(e) of the *IAA*). These procedural mechanisms, in turn, will help to ensure credible, transparent, and informed decision-making under sections 60 to 65 of the *IAA*.

For the foregoing reasons, ANA submits that a review panel hearing is the preferable procedure for gathering information, generating recommendations, and making decisions under the *IAA* about the adverse effects of the Great Bear Gold Project on matters of federal jurisdiction. Put another way, ANA believes that participating in a review panel hearing is far superior to merely reviewing and commenting on documents posted on the Registry (or participating in non-public workshops or meetings) in an Agency-led impact assessment.

FORMAT OF THE REVIEW PANEL

Due to the extreme and unique circumstance of Grassy Narrows, and of the risks posed to Grassy Narrows by the Great Bear Gold Project, the review panel should:

1) be jointly selected together with Grassy Narrows such that all review panel members have Grassy Narrows' free, prior, and informed, consent.

2) have the review panel members' scope, process, and timeline set in a way that gains Grassy Narrows' free, prior, and informed consent.

3) include within their scope an assessment of whether Grassy Narrows' free, prior and informed consent for the Project has been obtained, and of whether approval of the Project would be consistent with the *United Nations Declaration on the Rights of Indigenous Peoples*.

CONCLUSION AND REQUESTED ORDER

In the circumstances of this case, ANA concludes that referring this matter to a review panel will provide a more effective, efficient, and equitable process for conducting the impact assessment required for this designated project under the *IAA*. Given the project's location, size, scale, design/operations, and direct, indirect, and cumulative adverse effects on matters of federal jurisdiction as well as on ANA's aboriginal, treaty, and inherent rights, referral of the impact assessment to a review panel is both warranted and appropriate from the public interest perspective.

---

[1] Rod Northey, *Guide to the Canadian Environmental Assessment Act (2019 ed.)* (Toronto: Lexis Nexis), page 587.

Accordingly, ANA requests that you refer the impact assessment of the Great Bear Gold Project to a review panel at the earliest opportunity. Once this referral is made under the *IAA*, our client requests a meaningful partnership in jointly appointing review panel members and in the establishment of the terms of reference for the review panel.

Please feel free to contact the undersigned if you require additional information about this referral request, and we look forward to your reply.

Yours truly,

RE: Request to Designate Kinross Gold Corporation Great Bear Gold Mine Project as Subject to a Part II.3 Comprehensive Environmental Assessment under the *Environmental Assessment Act*

We are counsel to Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows First Nation" or "Grassy Narrows") in connection with the above matter. By this letter, ANA is requesting that you:

(1) designate by order; or
(2) initiate the process with the provincial cabinet that will lead to the designation by regulation,

the Kinross Gold Corporation Great Bear Gold Mine Project (the "Project"), including all ancillary facilities, infrastructure, and all activities with a risk of adverse impacts such as advanced exploration and closure plan related to the Project, as subject to a Part II.3 comprehensive environmental assessment under the *Environmental Assessment Act* ("*EAA*").

Background

Grassy Narrows is a First Nation, whose members have inherent, aboriginal and treaty rights under section 35 of the *Constitution Act, 1982*, and the status of a "band" within the meaning of the *Indian Act*. Members of Grassy Narrows live on and off the English River 21 Reserve, which is a reserve within the meaning of the *Indian Act* located in their traditional territory, in northwest Ontario. The members of Grassy Narrows, who exercise rights enshrined in Treaty No. 3, are Anishinabe people, many of whom engage in the practice of traditional Anishinabe activities, such as hunting, trapping, fishing, gathering, teaching, ceremony, and healing in their traditional territory. These activities are central to their identity, diet, culture, spirituality, health, wellbeing, and economy.

These traditional activities are and have been, under continual threat for more than half a century due to pulp and paper, logging, damming, and mining activities in, around, and upstream of, the traditional territory of Grassy Narrows. To take just one aspect of that threat – the release of mercury, a known human nerve poison, from these various operations. The sufferings members

the Grassy Narrows community have faced over more than half a century are well-documented due to pulp and paper industry discharges of mercury into the English-Wabigoon River system that have contaminated the fish and wildlife that community members eat. The community has also made efforts to prevent further mercury exposure of their food and environment from clearcut logging and dam activities in their traditional territory over the years. It has recently been confirmed that current effluent discharges from the Dryden pulp mill are elevating methylmercury levels in the English-Wabigoon River system by adding sulfate and dissolved organic carbon. The most imminent new mercury and methylmercury threats currently come from the proposed expansion of mining activities throughout their traditional territory.

Great Bear Gold Mine Project

A prime example of this problem is the Project, proposed by the Kinross Gold Corporation. The company proposes an advanced mining exploration program at Great Bear that will produce 1 million tonnes of waste rock and 400,000 tonnes of overburden, and with that waste rock release a number of toxic substances, including mercury, arsenic, cadmium, and substances which stimulate methylmercury production in the aquatic environment. An April 2024 report of an expert retained by the Grassy Narrows community, Dr. Kevin Morin, noted the following:

- there will be sources of mercury from ore processing as the tailings and concentrate from the process will contain mercury, with the processing possibly even causing mercury and other elements to leach more quickly and become more mobile in the environment; and

- sulphate concentrations in the treated effluent, can increase toxic methylation of mercury and other elements like cadmium and arsenic.

Dr. Morin concluded in the cover letter to his report:

> "…based on the information available at this time for the Great Bear Project, I remain concerned about the many potential environmental impacts that are not recognized and not anticipated by Kinross Gold and about the many impacts that are recognized but poorly addressed and characterized. My concerns pertain to both the proposed advanced exploration and the proposed mining".

Designation of the Great Bear Gold Mine Project Under Part II.3 of the *EAA*

Designation of the Project under Part II.3 of the *EAA* would contribute to a complete examination and understanding of the environmental, social, economic, and cultural impacts potentially faced by the Grassy Narrows community were the advanced exploration and proposed mining Project to proceed. It would also allow the province, pursuant to section 3.1 of the *EAA*, to harmonize its *EAA* regime with that of the federal *Impact Assessment Act* ("*IAA*") as the latter is not being applied by the federal government to the advanced exploration part of the Project, which expert reports have noted poses serious risks. Furthermore, the information-gathering and decision-making provisions under the *IAA* are primarily aimed at the project's effects within federal jurisdiction, not effects within provincial jurisdiction. Thus, application of the *EAA* to the Project, including its

advanced exploration phase, would: (1) contribute to a comprehensive environmental assessment review of the Project; (2) increase understanding of the measures necessary to protect the Grassy Narrows community from further harm to their health, well-being, and environment; and (3) contribute to ensuring, as a consequence of section 2.1 of the *EAA*, that there is no abrogation or derogation from the existing aboriginal and treaty rights of Grassy Narrows people under section 35 of the *Constitution Act, 1982*.

The Grassy Narrows community also understands that the constitutional status and scope of the *IAA* is currently in flux nationally and in Ontario due to a number of factors, including:

- the October 2023 Supreme Court of Canada ("SCC") reference opinion, which found the *IAA* to be substantially unconstitutional except in respect of federal projects or projects on federal lands;
- recent amendments to the *IAA* enacted by the Parliament of Canada that would appear to further shrink the jurisdictional scope and application of the *IAA* in respect of projects on non-federal lands; and
- the position of the Ontario government which argued before the SCC that the *IAA* was unconstitutional and which has also advanced that position in subsequent proceedings it has brought before the Federal Court of Canada.

In these circumstances, the application of the provincial *EAA* appears entirely warranted in order to avoid a complete gap in the coverage of federal and Ontario environmental assessment law in areas of purported provincial jurisdiction concerning advanced exploration and mining projects of the kind represented by the Project.

Designation of the Project by Order

As you are aware, section 2 of the *EAA* states that the Act's purpose "is the betterment of the people of the whole or any part of Ontario by providing for the protection, conservation and wise management in Ontario of the environment". However, from the information available to us it is not clear if the Project, or any part thereof, is an undertaking currently subject to the *EAA* under the class environmental assessment provisions of the Act. Section 15 of the *EAA* states that the class environmental assessment provisions of the Act (Part II.1) apply to:

> "9. Class Environmental Assessment for Activities of the Ministry of Northern Development and Mines under the Mining Act approved by the Lieutenant Governor in Council on December 12, 2012 under Order in Council 1952/2012."

The class environmental assessment document itself states that discretionary tenure decisions (related to surface rights and mining rights) and discretionary rehabilitation activities made by the Mines ministry are subject to the *EAA*.[1] Moreover, at page 20 of the class environmental assessment document it states that:

[1] Ontario, A Class Environmental Assessment for Activities of the Ministry of Northern Development and Mines under the *Mining Act* (Approved December 12, 2012; Amended July 3, 2014; Amended February 28, 2018) at 12.

> "Discretionary rehabilitation activities range from being small in size with minimal potential environmental effects to large-scale engineering and design activities that involve the disposal of hazardous materials and containment and treatment of acidic and metal-laden discharges."[2]

In the view of Grassy Narrows "large-scale engineering and design activities that involve the disposal of hazardous materials and containment and treatment of acidic and metal-laden discharges" fall squarely within the four-corners of the Project. Pages 46-47 of the attached report of Dr. Morin identify the following problems with water treatment during Kinross's proposed exploration and proposed mining for the Project:

> In summary for water treatment, Great Bear documents invoke water treatment as the major process that would prevent or minimize environmental impacts of proposed exploration and proposed mining. This is not literally true, because there will be fugitive contaminated water and contaminated dust leaving the site, but this fugitive contamination is ignored or not recognized in many reviewed Great Bear documents.
>
> In any case, water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts, and thus requires intensive study and characterization. However, at this time, water treatment for proposed exploration and proposed mining is ambiguous and contradictory among the documents. This should be expected because the input flows and input contaminant concentrations (ML-ARD) will not be known reliably for at least a few years. Nevertheless, there are serious concerns about water treatment now including the following.
>
> - Kinross Gold does not expect to treat site water to non-toxic levels. Instead, treatment would only be down to still-toxic levels based on the Metal and Diamond Mine Effluent Regulations. Thus, Kinross Gold intends to rely on significant dilution of its contaminated effluent within a "mixing zone" in the Chukuni River. Such a mixing zone would include zones of significant toxicity and would require formal authorization from Fisheries and Oceans Canada. In any case, this discharge of effluent would add to cumulative effects, which is a particular concern of Grassy Narrows First Nation.
>
> - Expensive and intensive treatment for ammonia, derived from blasting residues, is proposed. However, toxic levels of nitrate and nitrite, that always accompany the ammonia and which can cause eutrophication and other impacts in the Chukuni River and Dixie Creek, are completely ignored.
>
> - Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.
>
> - Ultrafiltration may substantially reduce effluent concentrations for those elements not fully dissolved, mixing-zone size, and cumulative effects. However, there are no details on this ultrafiltration in the reviewed Great Bear documents.

[2] Ontario, A Class Environmental Assessment for Activities of the Ministry of Northern Development and Mines under the *Mining Act* (Approved December 12, 2012; Amended July 3, 2014; Amended February 28, 2018) at 20.

> - Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge", which can reach "hazardous" and "special" waste levels in some jurisdictions. Thus, treatment sludge requires the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and sediments including soils and benthic ecosystems. All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge that will remain and be managed somewhere in perpetuity.

Grassy Narrows also notes the following from the MNDM Class Environmental Assessment document:

> Projects that have known or unknown and potentially substantial environmental effects (e.g., the rehabilitation of a large area of *tailings*) are classified as Category D. This category will involve extensive and detailed planning processes, including the preparation of a consultation plan and an analysis of *alternatives methods*. Projects assigned to this category will consist of MNDM's large-scale discretionary rehabilitation activities.
>
> The process by which an interested person(s) can make a request to the Minister of the Environment and Climate Change (or delegate) that a Category D project be made subject to an *individual environmental assessment* is described in Section 7.5.[3]

If the Project, or the advanced exploration part of it, is captured by the above provision, and Grassy Narrows suggests that it is, then, pursuant to section 16(6) of the *EAA*, a person may request that the Minister make an order on the grounds that the order may prevent, mitigate, or remedy adverse impacts on the existing aboriginal and treaty rights of the aboriginal peoples of Canada as recognized and affirmed in section 35 of the *Constitution Act, 1982*. By this letter, Grassy Narrows is making such a request because it asserts that its rights under section 35 will be violated by the Project, including the advanced exploration part of the Project. This is especially the case for this Project given the context of the extreme pre-existing cumulative impacts on this First Nation and its Territory and river. You, as Minister, have the authority under section 16(1) of the *EAA* to make such an order declaring a proposed undertaking referred to in section 15 to be a Part II.3 project and subject to comprehensive environmental assessment.

Designation of the Project by Regulation

In the alternative, if the Project is not subject to Part II.1 of the *EAA* as part of the class environmental assessment regime, then Grassy Narrows requests that you initiate a process whereby the provincial cabinet authorizes, pursuant to section 3(1) of the *EAA*, a regulation to be promulgated designating the Project, including its advanced exploration portion, as one to which the comprehensive environmental assessment requirements of Part II.3 of the Act apply.

---

[3] Ontario, A Class Environmental Assessment for Activities of the Ministry of Northern Development and Mines under the *Mining Act* (Approved December 12, 2012; Amended July 3, 2014; Amended February 28, 2018) at 45.

Designation of the Advanced Exploration Portion of the Project by Order or Regulation

In the further alternative, if the government is not willing to designate the entirety of the Project as subject to Part II.3 of the *EAA*, Grassy Narrows submits that it should at least designate the advanced exploration portion of the Project, including the closure plan, as subject to a comprehensive environmental assessment under Part II.3. In conjunction with the *IAA's* application to the mining portion of the Project, this would ensure that between the two laws, both the advanced exploration and mining portions of the Project would be subject to some environmental assessment. Although this is a less-than-ideal alternative to the comprehensive application of provincial environmental assessment authority to the full project, it is preferable to having no environmental assessment whatsoever given the serious risks posed by the extensive advanced exploration work proposed.

Summary

Given the historic harms from mercury exposure the people of Grassy Narrows have experienced due to industrial operations in their traditional territory, including the cumulative impacts of other industrial activities and land uses, the proposed advanced exploration and full mining activities from the Kinross Project that may result in their further exposure to mercury and other toxic substances, and the potential for a complete gap in the coverage of federal and Ontario environmental assessment law to this Project, Grassy Narrows requests that the Project, including its advanced exploration aspects or, in the alternative, just the advanced exploration portion of it, including the closure plan, be designated by order, or by regulation, as subject to Part II.3 of the *EAA* and its comprehensive environmental assessment requirements.

Yours truly,
CANADIAN ENVIRONMENTAL LAW ASSOCIATION

Dear MINES, IAAC, Kinross and Great Bear Resources:

RE: The Great Bear Gold Mine Project

I wrote to you on March 29 and April 15 to provide initial findings from Dr. Kevin Morin concerning metal leaching and acid rock drainage, water quality and hydrogeology with respect to the Great Bear Gold Project.

Please find enclosed:

- Dr. Morin's response to Kinross Gold's consultant, WSP. He concludes that he remains concerned about the many potential environmental impacts that are not recognized and not anticipated by Kinross Gold and about the many impacts that are recognized but poorly addressed and characterized. His concerns pertain to both the proposed advanced exploration and the proposed mining.

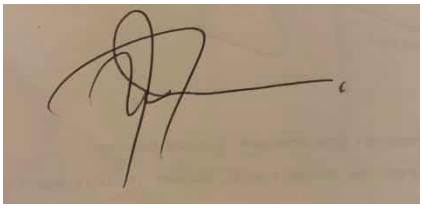
- Dr. Morin's report following his review of the technical documents provided to Grassy Narrows to date: Project Definition; Geochemical Characterization Workplan; Advanced Exploration Program Reclamation Strategy; Program Closure Plan (Draft for Indigenous Review); Hydrogeological Workplan; Surface

Water Quality Workplan; Fugitive Dust Best Management Practices Plan; PTTW Application for Dewatering; Draft Detailed Project Description; Water Treatment during Proposed Exploration and Proposed Mining.

Based on Dr. Morin's export reports, Grassy Narrows is extremely concerned that the project is moving ahead swiftly in the absence of required information and at great risk to the environment, the health, inherent, Treaty and Indigenous rights of Grassy Narrows.

I repeat Grassy Narrows' call to freeze the regulatory process work on this project until full credible information is available and the barriers to Grassy Narrows' meaningful involvement have been resolved. I also repeat Grassy Narrows' position that this project, including the extensive mining of valuable ore that the company is calling "bulk sampling", must be subjected to a rigorous environmental assessment.

Miigwetch,



Joseph B. Fobister, Lead Negotiator of Grassy Narrows Lands Protection Team

Grassy Narrows First Nation
c/o Cavalluzzo
474 Bathurst Street, Suite 300,
Toronto, Ontario M5T 2S6
Attn: Grassy Narrows Lands Protection Team

Dear Grassy Narrows Lands Protection Team,

RE: Great Bear Mining Project - Response to Kinross Gold on MDAG Initial Comments of March 27 2024

I have submitted to you two letters in the past about environmental concerns at the Great Bear Project, dated March 27 and April 11. These letters were based on some of my initial findings from some documents that were within my focus on metal leaching and acid rock drainage (ML-ARD), water quality, and hydrogeology. My review is now complete, including more detailed explanations for those earlier, initial comments as well as additional comments and concerns. My full review accompanies this letter of April 23.

Kinross Gold's consultant, WSP, replied to my first letter of March 27 on April 4. WSP sent a table with 18 issues, listed as "MSDAG [sic] Letter - Comments and Rationale" with a corresponding "GBR Response".

Please note that I did not include full "Rationales" with my initial letters because my detailed review was still in progress. Thus, it was not possible for WSP to provide satisfactory responses. My detailed "Rationales" were provided to you only today.

In any case, I explained that there was little reliable and professionally certified information on ML-ARD, water quality, and hydrogeology at this point for the Great Bear Project. Most Great Bear reports included labels like "preliminary", "draft", and "initial", which meant they were not complete, not certified as reliable, and subject to change one or more times in the future. In fact, some information and designs already changed substantially in 2023, as the accompanying review confirms.

Many of WSP's Responses reflected this. For example, the first WSP Response starts with:

> "The geochemical information presented in these reports represent initial draft documents for the Project, based on data collected in 2022 and early 2023 which was developed [sic] qualified professionals."

As I explained previously, my opinion is that preliminary, draft, and initial reports for the Great Bear Project that are not signed and certified by qualified professionals should not be reviewed. They are subject to change, and already some reports issued in 2023 contradicted others. I expect this to continue for at least a few years until final, reliable monitoring data and testwork are completed.

As a result, it is not worthwhile or meaningful to reply to WSP's Responses to my first letter. There are insufficient information and data at this time to debate and clarify many of my concerns and issues. There may or may not be sufficient information and data in future years. Only time will tell.

Therefore, based on the information available at this time for the Great Bear Project, I remain concerned about the many potential environmental impacts that are not recognized and not anticipated by Kinross Gold and about the many impacts that are recognized but poorly addressed and characterized. My concerns pertain to both the proposed advanced exploration and the proposed mining.

Sincerely,

Kevin A. Morin, Ph.D., P.Geo., L.Hydrogeo.

Report Summary

This MDAG review has focussed on the potential for contamination of water by metal leaching and acid rock drainage (ML-ARD) on, under, and around the Great Bear Project during proposed exploration and proposed mining.

It is important to note that some report titles for Great Bear contain the words "draft", "preliminary" or "initial", meaning newer drafts and revised final versions from Kinross Gold may or may not change from what has been reviewed here. Also, the first cover page for the Detailed Project Description of November 2023 says "draft" while the second WSP cover page does not. Thus, I have found that the reviewed documents for the Great Bear Project as a whole is a confusing mess of shifting, changing, contradicted, and assumed details, with none signed and certified by qualified professionals.

Also, the contents of some documents are password protected. This protected text and information cannot be extracted for detailed evaluation, quotation, review, and comment now or in the future. Thus, they preclude detailed reviews by Grassy Narrows First Nation, which is what Kinross Gold seeks.

Each section of this MDAG review looked in detail at a particular report on proposed exploration and/or proposed mining. The following paragraphs are the summaries taken from each section, and each section should be consulted for details and context.

Section 2 of this MDAG Review

For the password-protected Project Definition Document of December 2022, sufficient details and omissions are present for me to be very concerned about ML-ARD and water-quality degradation during and after the relatively large, at-least-four-years-long proposed Advanced Exploration that would essentially be a first phase of mining at Great Bear. These concerns carry over to the proposed mining.

Although this document is not marked as "draft" and is thus final, it contains many details contradicted by later documents as explained in later sections of this MDAG review. Thus, it is not possible to know exactly what is proposed for Advanced Exploration and, in turn, to know reliably how bad the environmental problems and impacts could be.

Section 3 of this MDAG Review

Problems detected in the January 2023 Geochemical Characterization Workplan include:

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross wants to proceed with

Advanced Exploration.

- All that is available now is 96 rock core analyses according to the September 2023 Reclamation Summary (see below), which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". In any case, the 96 samples were not collected and analyzed as required under the Ontario Mining Act (see next bullet). Thus, Kinross Gold and its consultants, WSP, are guessing how bad the contamination will be, but admit that some of it will be bad, and are likely years away from completing the ML-ARD work required under Regulation 240/00 of the Ontario Mining Act (Mine Development and Closure under Part VII Of the Act).

- The stated approach and methodology used for Advanced Exploration is "based on the requirements" of two British Columbia documents from 1997-1998 (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997). In reality, the Ontario Mining Act says the approach and methodology must be based on the much more detailed 2009 federal Prediction Manual, not just as "guidance" as Great Bear has done. Thus, the work for Advanced Exploration to date does not meet the Ontario Mining Act through Regulation 240/00 and does not meet the 2009 federal ML-ARD Prediction Manual (Price, 2009).

- Even if this Geochemical Characterization Workplan was applicable and consistent with the 2009 federal ML-ARD Prediction Manual, such work requires at least 2-3 years to obtain all required information and interpretations. Therefore, perhaps in 2025 or some year after, there might be sufficient ML-ARD for Advanced Exploration, but not any time soon.

Section 4 of this MDAG Review

Concerns on the Reclamation Strategy from September 2023 include the following.

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross Gold wants to proceed with Advanced Exploration.

- All that is available now is 96 core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". Also, 30 samples of overburden, which is intended to be left on surface and used for reclamation, were collected yet the results are not reported although there is ~50% probability that the overburden will release ML-ARD and thus be toxic. Kinross Gold and WSP are guessing how bad the contamination will be, but admit that some of it will be bad. They are likely years away from completing the ML-ARD work required under the Ontario Mining Act and Regulation 240/00, because the work for Great Bear was not initially consistent with Regulation 240/00. In part, this is because the 2009 federal ML-ARD Prediction Manual (Price, 2009) was not recognized or followed as required. Even the

definitions of ML-ARD acronyms used for the Great Bear Project are not correct according to the federal Manual, which is additional evidence the Prediction Manual is not being followed.

- The bad ML-ARD rock appears to be associated with "rapid acid generation" according to the Program Closure Plan (reviewed in the next section below). This is an incorrect explanation of the phenomenon, but still shows that the bad water quality will start coming out of the disturbed rock, including the underground mine walls, very quickly after initial disturbance. Informally, this is called "lag time" to ML-ARD, but most of the ML-ARD work has not yet been done to quantitatively estimate the lag time beyond "rapid". This contaminating rock will be stored on surface and possibly only later, likely after the lag time, some might be taken underground. When this rock contacts water underground as the workings partially flood and submerge, it will quickly release more contamination. This means the underground water flowing into the surrounding groundwater system, and the surface overflow if any, would have to be monitored and likely be treated for many years or in perpetuity after Advanced Exploration.

Section 5 of this MDAG Review

For the password-protected Program Closure Plan, Draft for Indigenous Review from November 2023, the following concerns were noted.

- In November 2023, the volume of overburden has approximately doubled from previous documents without an explanation. Because overburden generally has a 50% probability of releasing ML-ARD and contaminating water, overburden represents a major but unexamined threat to water quality on, around, and beneath the Great Bear exploration site.

- "Preliminary" criteria are provided for separating "PAG" and "NPAG" rock and for "NML" rock. However, these acronyms are not used in an accurate manner that is consistent with the 2009 federal Prediction Manual (Price, 2009) required by Regulation 240/00. The preliminary criteria are not rational based on ML-ARD science unless justified with detailed and intensive site-specific studies, which have not yet been completed and professionally certified for the Great Bear Project.

- The potential for ML-ARD after closure is presented all the way to detailed predictions of aqueous concentrations in mg/L for on-site water and effluent to the environment, but only after closure and not during operations when the water quality would be reasonably worse. However, these predictions are not explained in any detail, are not justified, appear anomalous, and are not certified by a qualified professional. Some predictions are actually pre-exploration baseline that are erroneously assumed to be re-established immediately at closure. Furthermore, these predictions are missing more than a dozen potential contaminants.

- The "PAG" rock, which would likely create the highest contaminant concentrations, is not included

in this Program Closure Plan, presumably because this "PAG" rock will be backfilled underground. However, when placed underground, this "PAG" rock will likely continue to release severe ML-ARD until submerged, at which point a relatively huge amount of accumulated contamination would be released into the underground water. After the mine is refilled to equilibrium, and the minewater begins flowing into the surrounding groundwater system and through the more than 500 km of permeable drillholes to the environment, it will contaminate large surrounding areas. This major risk to water quality and the environment is not even mentioned in this Closure Plan, which is a major omission.

- The backfilling of "PAG" rock at closure is the largest individual cost item for closure totalling around $10 million. However, this reflects the currently minimum volume based on preliminary, unreliable information. In the worst case, which was assumed in the Great Bear Project Definition and still not disproven here, total closure costs could exceed $20 million.

Section 6 of this MDAG Review

In the Hydrogeological Workplan from December 2022, there is a major omission that would preclude a reliable and comprehensive assessment of current baseline hydrogeologic conditions and of future impacts from proposed mining. The groundwater monitoring network does not extend far enough to the west and northwest, beyond the proposed western portion of the Tailings Management Facility.

Section 7 of this MDAG Review

In the Surface Water Quality Workplan from December 2022, there are insufficient information and details to determine if appropriate work is planned and conducted. This is because important details are listed only as "including". For example, major potential contaminants like manganese and thallium are not specifically listed, but perhaps they are implicitly included? There is no way to know.

Section 8 of this MDAG Review

Based on the final-draft Fugitive Dust Best Management Practices Plan of September 2023 for Advanced Exploration, this work is unacceptable because it grossly underestimates the potential impacts from ML-ARD geochemical contamination of soil, vegetation, water, and biota by dust. This work assumes the on-site sources of dust "would be similar in concentration to the background rock". This is wrong and ignores the ongoing ML-ARD assessment of ore, rock, and overburden.

Section 9 of this MDAG Review

In the PTTW (Permit To Take Water) Application for Dewatering, Final Draft, and its several

important appendices from October 2023, there are alarming errors and ambiguities that should preclude approval of PTTW. These should also trigger a detailed impact assessment, which this PTTW report conversely says is not needed for Advanced Exploration at Great Bear.

In the introduction to the main PTTW report, the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning because the actual total water withdrawal from the local groundwater/surface-water balance would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these flows are unrealistically low as explained here.

The errors begin with groundwater modelling that is based on long-term "steady state conditions" after the mine is "fully developed" and dewatered, and not on the correct, higher-inflow "transient conditions". Thus, inflow, pumping, and dewatering are significantly underestimated by the groundwater model and the PTTW Application. Additionally, there are problems with unrealistically low estimated effects on partial dewatering of Dixie Creek and other creeks and rivers. For example, simulated groundwater levels are around 9 m higher than measured around the mine and Dixie Creek, which artificially and incorrectly prevent additional dewatering of Dixie Creek.

Groundwater levels are shown to be drawn down during dewatering to a maximum of only 36 m even though the dewatered workings will be 600 m deep. This reflects (1) nearly fully dewatering of the shallow overburden and (2) the lack of admission on the likely huge drawdown and much larger "Zone of Influence" in the rock beneath the overburden.

Baseflows into Dixie Creek and other waterbodies can be critical to aquatic, benthic, and terrestrial ecosystems because of groundwater's typically different water quality and temperature compared to water already flowing at the surface. This becomes more critical during droughts when baseflow may be the main source of surface flows. The PTTW Application ignores the fact that more than 34 to 55% of existing baseflow would be lost during Advanced Exploration. It instead points out that the loss to groundwater would be only 2.4% and less of total flow depending on the chosen surface-flow statistic.

Overburden is routinely ignored in this PTTW document and its appendices, despite the proposed hundreds of thousands of tonnes of overburden likely having at least some ML-ARD potential and capacity to degrade water quality. In fact, some underground dewatering would be sprayed on the overburden for dust suppression, which in turn could lead to contaminated runoff across and off the site.

Section 10 of this MDAG Review

In the perhaps-draft Detailed Project Description of November 2023, the first cover page by Kinross says this document is "draft", but the second cover page by the authors, WSP, does not say "draft" so perhaps this is or is not the final document. If so, it has not been signed by qualified professionals and thus should be rejected.

In any case, there are so many problems, misleading statements, errors and omission concerning ML-ARD, water quality, and environmental impacts that they cannot all be summarized well here. These problems include the following.

- There is a false statement that there will be no sources of mercury from the ore processing when in fact the tailings and concentrate from the process will contain mercury. The processing could even cause mercury and other elements to leach more quickly and become more mobile.

- Contrary to the impression given by this Detailed Project Description, cyanide destruction is not perfect and can simply mask the cyanide temporarily in the environment, but the important testwork to determine this has not yet been done for the Great Bear Project.

- Significant impacts on water quality can arise from seemingly benign proposed activities like paste backfill of tailings into the underground mine and dewatered filter-cake tailings. However, the potentials for serious impacts are not recognized or not even mentioned in this perhaps-draft Great Bear document that can supposedly be used to determine what impacts could occur.

- Storm events and equipment upsets can lead to relatively large variations and unexpected impacts, day-to-day or even hour-to-hour, during proposed exploration and proposed mining. Instead, these Great Bear documents use averages like monthly which incorrectly assume flows will be the same every day of a month which is far from reality. Environmental impacts and spills can also be caused by large variations, as well as longer-term averages, so the environmental risks of proposed exploration and proposed mining at Great Bear remain mostly unknown and not identified.

- Nonsense pseudo-scientific statements are used, like the aggregate required to build the project would be “nonreactive mine rock and overburden” which does not exist. This clearly shows that experienced and qualified professionals were not included in the writing of this perhaps-draft Detailed Project Description. If there is a true commitment to “nonreactive mine rock and overburden” which does not exist, then the Great Bear Project stops now.

- There is a lack of ML-ARD assessments for some site components like aggregate.

- There is a prevalent but likely false belief that “NPAG”rock will have little to no impacts on ML-ARD, water quality, and the environment. However, this has not been proven for the Great Bear Project and is likely wrong based on other minesites around Canada. “NPAG” rock can actually generate more acid than “PAG” rock and could still release seriously contaminated levels of many metals and other elements at near-neutral pH.

- The financial assurance to ensure proper and fully paid closure of the proposed Great Bear Project is grossly underestimated based on existing information. Furthermore, the financial assurance should also include contingencies for costs of early or premature closure, but it does not.

- There are likely devastating, expensive, and unrecognized ML-ARD consequences on water quality from the proposed relocation of "PAG" rock into the underground workings after operation.

- The ongoing, unproven, and likely wrong, belief continues that overburden would be environmentally benign, can be used across the site for reclamation, and can be sprayed with water to control dusting when it could instead create contaminating water around, below, and beyond the Great Bear site.

- There are unfounded beliefs that dewatering during exploration and mining would have minimal effects on the local and regional water balance, and would not significantly dewater surface creeks and lakes including their environmentally important baseflow. These false beliefs are based on flawed groundwater modelling for the Great Bear Project explained earlier in this MDAG review.

- There is a false belief that dust blown off the site during proposed exploration and proposed mining and into the surrounding environment, vegetation, soil, water, and aquatic ecosystems is benign at "background" levels.

- A false belief is stated that only elevated and toxic ammonia, and no other contaminating nitrogen species from explosives that consistently accompany the ammonia, will appear in mine water during proposed exploration and proposed mining.

- There is an unsupported and likely substantially underestimated statement that the mine walls in the pits and underground workings "may potentially contribute minor quantities of metals to the mine water" instead of the more typical significant quantities of metals seen at many other minesites around Canada. This is taken as far as the likely ludicrous statement that there would be "Potential for creation of fish habitat in new pit lakes, expected to be re-connected [sic] to the Dixie Creek system".

- There is no recognition of the implications, costs, and impacts of storing months of contaminated mine water on the site should one or more "unexpected" yet currently predictable inorganic contaminants and ML-ARD occur on the site water during and after proposed exploration or proposed mining.

Section 11 of this MDAG Review

In summary for water treatment, Great Bear documents invoke water treatment as the major process that would prevent or minimize environmental impacts of proposed exploration and proposed mining. This is not literally true, because there will be fugitive contaminated water and contaminated dust leaving the site, but this fugitive contamination is ignored or not recognized in many reviewed Great Bear documents.

In any case, water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts, and thus requires intensive study and characterization.

However, at this time, water treatment for proposed exploration and proposed mining is ambiguous and contradictory among the documents. This should be expected because the input flows and input contaminant concentrations (ML-ARD) will not be known reliably for at least a few years. Nevertheless, there are serious concerns about water treatment now including the following.

- Kinross Gold does not expect to treat site water to non-toxic levels. Instead, treatment would only be down to still-toxic levels based on the Metal and Diamond Mine Effluent Regulations (MDMER). Thus, Kinross Gold intends to rely on significant dilution of its contaminated effluent within a "mixing zone" in the Chukuni River. Such a mixing zone would include zones of significant toxicity and would require formal authorization from Fisheries and Oceans Canada. In any case, this discharge of effluent would add to cumulative effects, which is a particular concern of Grassy Narrows First Nation.

- Expensive and intensive treatment for ammonia, derived from blasting residues, is proposed. However, toxic levels of nitrate and nitrite, that always accompany the ammonia and which can cause eutrophication and other impacts in the Chukuni River and Dixie Creek, are completely ignored.

- Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

- Ultrafiltration may substantially reduce effluent concentrations of elements not fully dissolved, mixing-zone size, and cumulative effects. However, there are no details on this ultrafiltration in the reviewed Great Bear documents.

- Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge", which can reach "hazardous" and "special" waste levels in some jurisdictions. Thus, treatment sludge requires the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and sediments including soils and benthic ecosystems. All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge that will remain and be managed somewhere in perpetuity.

1. Introduction

Metal leaching (ML) and acid rock drainage (ARD) are often water-chemistry and water-quality issues for minesites (e.g., Morin and Hutt, 1997 and 2001). As a result, the accurate prediction and control of ML-ARD at mining projects and proposed minesites in Ontario are high priorities of the provincial and federal governments.

This is explained in Part 7 (*Metal Leaching and Acid Rock Drainage Requirements*) of Ontario Regulation 240/00 (*Advanced Exploration, Mine Development and Closure under Part VII of the Act*), and in the federal ML-ARD Prediction Manual (Price, 2009). Section 57(1) of Regulation 240/00 states,

> "A program shall be undertaken to sample all materials remaining on the site that have been excavated, exposed or otherwise disturbed by mining activities, including but not limited to,
>
> (a) drill core;
> (b) metallurgical samples;
> (c) pit walls;
> (d) existing waste rock, ore, concentrate and *overburden* [MDAG emphasis] piles;
> (e) construction rock; and
> (f) tailings."

For detailed guidance, Ontario Regulation 240/00 states,

> "The sampling program shall be conducted by a person who is qualified in Ontario as a professional geoscientist, professional agrologist or professional engineer in accordance with a report prepared by William A. Price on behalf of the Mine Environment Neutral Drainage (MEND) program, entitled 'Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials', MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..." [Price, 2009]

ARD is caused by oxidation of sulphide minerals, which are found at the Great Bear Project, particularly iron-bearing sulphides like pyrite and pyrrhotite. Whether sulphide minerals are present or not, weathering can still lead to accelerated metal leaching (ML). For example, the simple dissolution of near-neutral or alkaline carbonate minerals can release metals like manganese and zinc into the water. Thus, ARD is a subset of the more generic ML.

In practice, ML is not limited to true metals in the Periodic Table, but to all elements that could become potential environmental contaminants. For example, sulphate and nitrate are regularly included in ML assessments. Sulphate can reportedly increase the methylation of mercury and other elements like cadmium and arsenic.

Therefore, ML-ARD is an acronym representing the full spectrum of inorganic water chemistry and quality on, beneath, and around a minesite. Put simply, ML-ARD potential is synonymous with the potential for inorganic water contamination and the degradation of on-site water quality.

Kinross Gold Corporation (Kinross Gold) proposes Advanced Exploration and later mining at its Great Bear Gold Mining Project in the Red Lake mining district of Ontario, approximately 25 km southeast of the Town of Red Lake. The Great Bear Project is located in the Interim Area of Interest for Mining of Asubpeeschoseewagong Netum Anishinabek (ANA), which Kinross documents also name as Grassy Narrows First Nation (GNFN). The Great Bear Project is also in an area where Grassy Narrows First Nation people use the land and water to practice their Indigenous way of life. It is located upstream of the English River which flows directly to the Grassy Narrows village site and Grassy Narrows' most important fishing grounds.

Through Cavalluzzo LLP, the Grassy Narrows Lands Protection Team has asked me, Dr. Kevin Morin of the Minesite Drainage Assessment Group (MDAG), to review and comment on the proposed exploration and proposed mining. This MDAG review focuses on predicted surficial and subsurface ML-ARD and water quality on and around the Great Bear Project.

My qualifications for making the comments in this review document include the following. I have been assessing water contamination at minesites by metal leaching and acid rock drainage (ML-ARD) for 46 years. I have done this at several hundreds of exploration, operating, and closed mining-related sites on all continents except Antarctica, from north of the Arctic Circle to south of the Tropic of Capricorn, in biogeoclimatic zones ranging from virtually no annual precipitation up to a rare daily rainfall of one meter. I earned my Doctor of Philosophy degree in contaminant hydrogeology from the University of Waterloo, where my supervisor was the renowned Dr. John Cherry along with a thesis committee including Drs. Emil Frind (a well-known groundwater modeller) and Eric Reardon (a well-known geochemist). To date, I have authored or co-authored 99 published papers and presentations, five books, and 80 online case studies. I have been and am a peer reviewer for a number of international journals related to ML-ARD and environmental contamination. More details can be found at www.MDAG.com.

The Kinross documents reviewed in the following sections are listed below. Again, the main focus is on the potential for contamination of water by ML-ARD on, under, and around the Great Bear Project during proposed exploration and proposed mining.

- Project Definition Document (December 2022)
- Updated Site Plan
- PTTW Application for Dewatering, final draft (October 2023)
- Fugitive Dust Best Management Practices Plan, final draft (September 2023)
- Reclamation Strategy (September 5, 2023)
- Program Closure Plan, Draft For Indigenous Review (November 2023)
- Surface Water Quality Workplan (December 21, 2022)
- Hydrogeological Workplan (December 21, 2022)
- Geochemical Characterization Workplan (January 9, 2023)
- Preliminary Impact Assessment Methodology, draft (May 31, 2023)
- Preliminary Listing of Potential Valued Components for the Great Bear Project (May 31, 2023)
- Initial Project Description (June 1, 2023)
- Detailed Project Description (November 2023)

- PowerPoint Presentation by Kinross to ANA (November 10, 2023)
- ANA IPCA Map

It is important to note that some report titles above contain the words “draft”, “preliminary” or “initial”, meaning newer drafts and revised final versions from Kinross Gold may or may not change from what has been reviewed here.

Also, the contents of some documents above are password protected. This protected text and information cannot be extracted for detailed evaluation, quotation, review, and comment now or in the future. This precludes the detailed review by Grassy Narrows First Nation that Kinross Gold seeks. I strongly recommend that unlocked versions of all Kinross documents be obtained and kept by Cavalluzzo LLP and the Grassy Narrows First Nation for future reference and usage.

2. Project Definition Document (December 2022)

The Great Bear Resources Great Bear Advanced Exploration Project Project Definition Document, dated December 2022 by WSP E&I Canada Limited (WSP), is a password-protected document from which its content cannot be extracted or copied for detailed evaluation and reinterpretation.

In the Preface of this document, WSP states,

> "The Project as described in this document is subject to change as engineering progresses, in response to feedback from government agencies, Indigenous communities and stakeholders, as well as constraints not currently known, that are identified by ongoing environmental baseline and engineering works, and Indigenous consultation and engagement."

No new or updated Project Definition could be located and thus this version from December 2022 is reviewed here from the perspective of ML-ARD and potential water contamination.

Section 1.3 explains the objective of the proposed Advanced Exploration and its key activities:

> "The objective of this Project is to obtain additional information on the known mineralized zones (LP Fault, Limb Zone and Hinge Zone; Figure 1-3) through underground drilling, and to extract a bulk ore sample of up to 60,000 tonne (t) by underground mining methods. Extraction of a bulk sample allows the testing of representative areas of the mineralization off site, in order to gain a better understanding of the geology of the mineralized zones including, grade, structural controls on the mineralization, continuity, mining dilution, optical sorter performance and metallurgical recoveries. This information will support the assessment and development of a viable commercial production scenario.
>
> "The Project will also support future engineering designs by improving knowledge of key factors (ground conditions, water inflows, costs, labor, etc.). It will also improve the knowledge base to increase the confidence in environmental predictions associated with the proposed underground mine and to a lesser extent open pit mine.
>
> "Key Project activities are provided below:
> - Establish portal(s) and decline(s) to provide access underground in order to establish required underground workings
> - Develop drill platforms off the decline to facilitate efficient underground drilling of the known mineralized zones at depth
> - Extract up to 60,000 t of ore (bulk) sample from test stopes and drifts in the mineralized zones
> - Transport the ore to surface along the decline(s) by truck for crushing, sorting and sampling; samples will transported off site by highway truck for test processing
> - Mine rock that must be removed from the underground workings in order to provide access to the ore will be brought to surface by truck and will be stored in stockpile(s) unless appropriate for use as a construction material on site
> - Additional activities on surface and underground, such as environmental management."

These quotations raise several concerns as explained next.

Section 1.4 "Consultation to Date" with First Nations mentions Wabauskang First Nation (WFN) and Lac Seul First Nation (LSFN) in several places including an Exploration Accommodation Agreement. In contrast, Grassy Narrows First Nation (GNFN) in mentioned only twice, including where the Ontario Ministry of Mines instructed Kinross Gold to include GNFN in notifications of significant updates on exploration works. Later, Section 7.4.1 adds,

> "On September 29, 2022, the Company communicated its interest in an introductory meeting to GNFN, who respectfully declined the offer."

Section 1.5 on "Involvement of Federal Agencies" in this Project Definition starts by saying "Not currently applicable". Then it clarifies:

> "No Federal government departments or agencies are expected to grant Federal land or providing financial support to the project (include indirect funding support, such as for infrastructure and training). There is the potential that Federal departments may be required to provide environmental approvals or authorizations (see Section 7.3.1)."

Federal agencies like Fisheries and Oceans Canada will very likely be involved in authorizations as the Great Bear Project intends to discharge toxic water including from its advanced-exploration treatment plant into fish-bearing waters and fish habitat as "mixing zones" requiring authorizations. This is discussed further in Section 11 of this MDAG review.

Section 5.1.1 on Existing / Previous Development, Operations and Facilities says:

> "The first exploration work documented by Geology Ontario on the Property dates from 1944. Prior to acquisition by Great Bear Resources Ltd. in 2017, 176 diamond drillholes had been completed totalling 32,602.8 metres (m).... As of October 2022, there has been over 500,000 m of diamond drilling on the Property."

For understanding how groundwater might move during and after proposed Advanced Exploration, these hundreds of drillholes more than 500 km in total length create very permeable pathways for subsurface water to travel long distances quickly, in violation of normal hydrogeologic principles like hydraulic gradients and hydraulic conductivities. This is not acknowledged in other Great Bear documents, as explained in sections of this MDAG review such as Sections 6 and 9.2.

Section 5.1.3 on Geology and Mineralogy says:

> "The Property lies locally within a regional northwest-southeast trending belt of metavolcanic and metasedimentary rocks, bound by intrusive batholiths (see Figure 5-1). The Project is targeting gold mineralization, currently identified within three mineralized zones (see Figure 1-3):
>
> - LP Fault Zone, disseminated gold within high strain
> - Limb Zone (previously known as the Dixie Limb), silica-sulphide replacement
> - Hinge Zone, quartz veining."

The 2009 federal ML-ARD Prediction Manual (Price, 2009) shows that the ML-ARD and potential contamination from each of these zones requires separate ML-ARD evaluations. However, the proposed underground drifts are from a limited area of the ore zones, contrary to a statement that Advanced Exploration is needed to check "the continuity of underground access gold deposits" (see below).

Section 5.1.4 on Geochemical and Geotechnical Considerations states:

> "Geochemical characterization work has been initiated in order to support potential future development, including meeting the requirements of the Mine Rehabilitation Code for a future Advanced Exploration Closure Plan. Ongoing work include static testing (acid base accounting, short-term leaching), mineralogy and metal content. Humidity cells and rain barrel tests are also proposed. The conservative [worst-case] assumption pending results of the comprehensive testing program, is that ore and mine rock is potentially acid generating. This assumption will be amended on receipt of the pending test results and further assessment."

This worst-case assumption (incorrectly stated as "potentially acid generating" in comparison to the federal ML-ARD Prediction Manual) that all ore and mine rock will release ML-ARD could still be the case now, despite recent statements to the contrary (see the sections below in this review). This is because important ML-ARD work has not been completed and then certified by a qualified professional.

Section 5.1.4 also describes the overburden at the Project, which requires ML-ARD assessment equal to those of waste rock and ore according to the federal ML-ARD Prediction Manual and Ontario Regulation 240/00.

> "At the northwest portion of the Property, surficial soils are glaciofluvial in origin, consisting of sands and gravels. In the central portion of the Property, the surficial soils are described as deep-water deposits comprised of laminated to varved clay, silt and fine sand (Natural Resources Canada, 1996). Based on current exploration drilling information, overburden thickness at the Property is expected to range between 0 to 40 m. There are limited bedrock exposures within the Project area. Overburden encountered to date is a mix of sand, gravel and clay; however zones of soft sensitive clays may be encountered. An extensive geotechnical drilling program is currently underway on the Property to further investigate these and other aspects."

Section 5.1.5 on Proposed Mining Activities contains many important details such as:

> "There is no production mining proposed for the site." [MDAG Note: This appears to be a play on words because significant mining for several years is in fact proposed and Section 5.1.5 is specifically entitled "Proposed Mining Activities"; see my comments below on Section 5.1.8]. This Project includes use of underground mining methods to obtain a bulk sample of up to 60,000 t. The work is to be initiated in 2023, pending consultation, regulatory approvals and a corporate decision to proceed."

Kinross Gold further explained details of the proposed Advanced Exploration in Section 5.1.5:

> "The goal of the advanced exploration program (and ongoing exploration drilling from surface), is to collect additional information to support a decision on whether to proceed to develop a mine and to support engineering design. The advanced exploration bulk ore sample will be trucked off site over the existing Provincial road network to an existing mineral testing facility. No onsite processing is proposed.
>
> "GBR proposes to collar one or two portals from surface (approximately 6 m by 6 m) and to develop associated decline ramp(s) of approximately the same dimension. Secondary

egress and ventilation may be provided through a raise. The ramp is projected to extend to a vertical depth of approximately 600 m below surface and length of approximately 9,000 m during the Project. A preliminary long-section and plan view of the advanced exploration underground workings showing the preferred portal and raise location is provided in Figure 5-2 and Figure 5-3. The ramp is designed to provide access to the investigation areas, promote efficient truck haulage and reduce ventilation losses. Personnel will access the underground workings by means of the ramp. A shaft is not proposed for the Project.

"A bulk sample will be extracted from underground workings developed from the ramp(s) using conventional drilling and blasting using explosives, from several locations within the deposit. Blasting is proposed to use prepackaged and bulk explosive products....

"The objective of this Project is to obtain additional information on the known mineralized zones (LP Fault, Limb Zone and Hinge Zone; see Figure 1-3) through underground drilling and extraction of a bulk ore sample. Extraction of bulk sample allows testing of representative areas of the mineralization in order to gain a better understanding of the geology of the mineralized zones including, grade, structural controls on the mineralization, continuity, mining dilution, optical sorter performance, crushing and grinding properties and metallurgical recoveries to support development of a viable commercial production scenario.

"Industry-specific factors that were considered by GBR when establishing the size of the bulk sample include as follows:

- The proposed bulk sample is approximately 1% of the currently defined mineralized envelope and is consistent with other Ontario advanced exploration projects, such as the Timmins West Project (100,000 t), Sugar Zone Project (70,000 t) and Upper Beaver Project (60,000 t)
- Representative bulk samples extracted using realistic mining methods that help to prove the continuity of underground access gold deposits are very important to potential financiers
- National Instrument 43-101 resource definition and economic modeling standards are becoming more stringent to satisfy stricter due diligence standards imposed by industry and the investment community, often requiring bulk samples to validate and refine resource models prior to production decisions."

The problem with these details is that the three reasons given by Kinross Gold do not justify the 60,000 t bulk sample nor the proposed locations for the removal of the bulk sample. For example, the figure shows that most of the bulk sample will be taken from two laterally-limited areas. As a result, most of the ore from northwest to southeast will not be sampled. This is not consistent with proving "the continuity of underground access gold deposits".

Section 5.1.8 on Project Duration and Rate of Mining shows that Underground Development will take place across more than four years "on a continuous (24-hour) basis" and the Bulk Sample will be collected across roughly 2.5 years. These details plus the two 6x6 m portals show this is not typical Advanced Exploration to determine if future mining might be justified, but this is the first phase of mining.

Section 5.3.8 Buildings and Large Facilities includes Table 5.2 "Primary Buildings and Facilities on Surface". "Mine Rock Stockpiles (2)" has an approximate scale of 1,000,000 t, although it is not clear on whether this is maximum capacity or expected capacity. This is only clarified later under Section 5.4.3 (see below) which is the only description of the volume of disturbed waste rock (1,000,000 t) left on site simply to obtain 60,000 t of ore (a ratio of 17:1). This implies a large percentage of waste rock will be mined during Advanced Exploration, which further supports the view that Advanced Exploration would be the first phase of mining.

Remarkably, the various ponds listed in Table 5.2 are only described as lateral areas and do not provide depths and volumes, precluding a discussion of mass balances and spills due to extreme weather events and failures of the treatment plant. Also, the total catchment of this proposed exploration site is not provided despite all its runoff and infiltration requiring routine monitoring and treatment as needed. These are serious omissions. These omissions continue in the perhaps-draft Detailed Project Description, reviewed in Section 10 below.

Despite 60,000 t of ore being mentioned many times in this Project Definition, Section 5.4.3 "Stockpiles" is the only section of this Project Definition that mentions the substantially greater amount of waste rock with ML-ARD potential:

> "It is estimated that a total quantity of approximately 1,000,000 t of mine rock will be generated and stockpiled during the Project."

Additionally:

> "A stockpile of up to 100,000 m^3 [of overburden] is proposed", which likely means about an additional 200,000 t of disturbed overburden.

Notably, less than a year later, documents (see the later sections of this MDAG review below) have increased the overburden to ~400,000 t with no clear explanation for it.

Overburden stockpiles at minesites around Canada have released significant ML-ARD, which is why they are specifically mentioned and referenced through the Ontario Mining Act, but this Project Definition fails to recognize this. Later Kinross Gold documents fail to show the overburden stockpile and fail to show its runoff reporting to ML-ARD treatment (e.g., the undated "AEX Site Plan - Updated.pdf" on which overburden is called "topsoil"). For example, "Memo - Reclamation Strategy - Sept 5 2023.pdf" says,

> "Runoff from the overburden stockpiles (will be monitored and treated to manage suspended solids as required and discharged)".

The undated "AEX Site Plan - Updated.pdf" does not show this. This is one of many glaring contradictions and errors among the Great Bear documents reviewed here.

The understanding of groundwater at this Project is incomplete or contradictory. Section 6.25. Says:

> "The bedrock is generally tight with some potential for limited groundwater flow in the upper fractured bedrock and a few deep structures."

However, a figure in Section 5.5.2 shows groundwater as the only source of inflowing water to the underground workings. Thus, Kinross is saying groundwater inflow is "limited" but also is the only source of this water that has to be actively pumped out of the mine. This escalates to serious errors in groundwater modelling explained in Section 9.2 below that incorrectly predicts relatively low groundwater inflow and relatively little dewatering of surface creeks and lakes.

Section 6.2.6 Air Emission Information has an important omission concerning ML-ARD, environmental impacts, and cumulative effects. This section simply says,

> "A meteorological station has been established on the site, and baseline air quality and sound data is being collected. Based on a review of current Project, air emissions are anticipated to be limited and no offsite impacts are predicted. A management plan will be established to mitigated dust from materials movement and traffic on gravel roads."

However, hundreds of thousands of tonnes of blasted waste rock plus disturbed overburden will remain on site in piles up to 30 m high, likely in perpetuity after Advanced Exploration. This contaminated, blasted, and disturbed materials can release ML-ARD contaminated dust that can be carried into the surrounding environment where it can affect and degrade water quality, soil quality, vegetation, microbes, fish, and animals. As explained in Section 8 of this MDAG review, this invalidates the fugitive dust study for the Great Bear Project.

In summary of this password-protected Project Definition Document of December 2022, sufficient details and omissions are present to be very concerned about ML-ARD and water-quality degradation during and after the relatively large, at-least-four-years-long proposed Advanced Exploration that would be essentially a first phase of mining at Great Bear. These concerns carry over to the proposed mining. Although this document is not marked as "draft" and is thus final, it contains many details contradicted by later documents as explained in later sections of this MDAG review. Thus, it is not possible to know exactly what is proposed for Advanced Exploration and thus to know reliably how bad the environmental problems and impacts could be.

3. Geochemical Characterization Workplan (January 9, 2023)

This very short, three-page summary of ML-ARD "geochemical characterization", apparently issued in January 2023 by WSP, does not provide much information to review and comment on since it is only a "Workplan". However, later documents show this Workplan was not followed.

Under "Purpose of the 2023 Program", it says:

> "Samples that have been or will be tested as part of the geochemistry program include drill core (representing mine rock), overburden, and synthetic tailings generated from metallurgical test programs conducted in the laboratory. Related water quality modelling will be undertaken in 2023, focusing on the proposed Advanced Exploration (AEX) phase. Additional water quality modelling, representing the overall Project, will be undertaken at a later date."

As explained below, this Workplan is not sufficiently thorough and complete under the 2009 federal ML-ARD Prediction Manual (Price, 2009) to justify water-quality modelling and its conclusions. In any case, it is now April 2024 and no verified modelling results from 2023 have been found.

Under "Mine Rock Static Testing", this Workplan states,

> "A mine rock characterization program was initiated in 2022. A total of approximately 300 samples of drill core were collected for this purpose as part of field work in 2022. Drill core samples were obtained from a variety of locations and depths around the deposit, including rock in the vicinity of the proposed open pit and underground developments, along with the proposed AEX volume. Samples of all major rock types were collected. The purpose of this work is to evaluate the ML/ARD potential of the rock and help determine how mine rock may need to be managed.... Testwork is underway and results will be available in the first quarter (Q1) of 2023."

However, nine months later in September 2023, the Reclamation Strategy (see the next section of this MDAG review) mentions only 96 samples that are only "proximal" and thus not necessarily representative of rock to be removed for Advanced Exploration or proposed mining. Perhaps the other 200 samples are not relevant for Advanced Exploration and proposed mining, but then because they are "proximal" it is possible that the 96 samples are not relevant either.

Under "Mine Rock Static Testing", it says

> "All samples will be tested for Acid Base Accounting (ABA) parameters (that includes paste pH, sulphur content and speciation, and Neutralization Potential content and form) and elemental content analysis (aqua regia digestion and ICP analysis). Some of the samples will be subjected to more detailed static tests including the Shake Flask Extraction (SFE) test, Net Acid Generation (NAG) test, and Rietveld X-Ray Diffraction. Testwork is underway and results will be available in the first quarter (Q1) of 2023."

This is insufficient detail to ensure the correct tests are being done. In fact, "aqua regia" is a partial digestion that detects only part of the heavy metals and other elements in a sample, and thus is not acceptable for most ML-ARD work including comparisons to total crustal abundances.

Also, the September 2023 Reclamation Strategy (see the next section) mentions the results of 96 core samples, without stating which methods were used and what the analytical results were. All this information "will be available in the first quarter (Q1) of 2023", but more than a year later the information is not available as qualified-professional-certified results and interpretations.

Under "Mine Rock Kinetic Testing Programs", it says:

> "Kinetic tests are used to assess how a material responds to oxidation / weathering processes over time, and are used to estimate the time until samples may start to produce acidity and the rates at which the samples release metals. Several mine rock kinetic testing programs will be conducted in 2023, including a program conducted in the laboratory (humidity cell tests) and a program conducted in the field (field leach barrel tests).
>
> • The humidity cell test program will be initiated in the laboratory in 2023. Ten tests are currently planned and the specific number of tests will be confirmed following receipt of the static testing results. Samples to be tested will include key mine rock materials with a risk for ML/ARD along with test samples that are representative of typical Project mine rock. Initial reporting on the humidity cell tests will be available in Q4 2023."
>
> • A field leach barrel program will be initiated in the spring of 2023. Ten tests are currently planned but the specific number of tests will be confirmed following receipt of the static testing results. The objective of this program is to evaluate rates of sulphide oxidation and metal release under field conditions. This information will be integrated with the results of ongoing laboratory humidity cell tests to evaluate lag times to acid onset and metal release from mine rock. The tests will be routinely monitored throughout the open water season in 2023. Initial reporting on the field leach barrel program will be available in Q4 2023."

It is now April 2024. Where are the progress reports "available in Q4 2023"? In any case, these tests take at least one year, and often longer, to complete according to the federal ML-ARD Prediction Manual (Price, 2009). Thus, reliable and professionally certified results will not likely be available until late 2024 or 2025 at the earliest.

Under "Overburden Characterization", it says:

> "A preliminary geochemical characterization program for overburden is underway. Thirty samples of the various types of overburden present around the property were collected as part of field work conducted in 2022. Samples were submitted to the laboratory for static testing (ABA and elemental content) and a subset of samples were selected for more detailed static tests. Results will be available in Q2 2023."

Strangely, in the September 2023 Reclamation Strategy (see next section), the preliminary results are mentioned for mine rock but not for overburden. This is important because this Project Definition estimates there will be about 200,000 tonnes of overburden disturbed (with recent documents less than a year later saying ~400,000 t). This is about three times more overburden than the ore being mined as a bulk sample. On average around Canada, about half of overburden at mineral deposits has significant ML-ARD potential, so there is a significant risk that Great Bear overburden will devastate water quality on, beneath, and around the site.

Under "Mine Water Quality Estimates", this Workplan states:

> "Mine water quality estimates for the AEX phase will be prepared in Q1 2023. Modelling will be conducted via mass balance approaches and will be supported by the AEX site water balance and available geochemistry data. The model results will be used to ensure that site water management needs are identified and addressed. Additional water quality modelling, representing the overall Project, will be undertaken at a later date as the project advances."

Mine-water mass balances are not often representative of leachates from sulphide-bearing rock and overburden as found at the Great Bear Project. There is no justification here for mass-balance modelling and its results could be irrelevant for Advanced Exploration as well as proposed mining. This approach should be examined in detail including the data on which it is based once qualified-professional-certified documents become available.

Under "Technical Data Collection Methodologies", it says:

> "The approach and methodology for the geochemistry programs were based on the requirements described under the Ontario Mining Act; namely guidance found within the documents DRAFT Guidelines and Recommended Methods for the Prediction of Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (Price 1997), and Policy for Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (MEM 1998). Additional guidance was provided by the reference document Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND 2009), which represents best practice and industry standard approaches and methodologies for ML/ARD sampling and characterization in Canada."

In fact, this is wrong. The Ontario Mining Act states:

> "The sampling program shall be conducted by a person who is qualified in Ontario … in accordance with a report prepared by William A. Price on behalf of the [federal] Mine Environment Neutral Drainage (MEND) program, entitled "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials", MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..."

Therefore, for the Great Bear Project, "[t]he approach and methodology for the geochemistry programs were based on" 1997 and 1998 British Columbia documents with only "guidance" from the federal Prediction Manual. In reality, the approach and methodology are required under the Act to be based fully on the 2009 600-page federal Prediction Manual, which instead was only used for "additional guidance". The 1997 and 1998 BC documents (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997) provided relatively little detailed instructions compared with the federal Prediction Manual, so the Great Bear ML-ARD testwork started off as likely insufficient under the Prediction Manual and would have to be expanded.

Under "Field and Laboratory Work Timing", it says:

> "Some field and laboratory work associated with the geochemical characterization programs was conducted in 2022 as described in the previous sections. Additional lab work is planned for 2023 as outlined above. Field work will be conducted in 2023 to construct the Field Leach Barrel tests and monitor and collect leachate from the tests. Reporting for the various programs will be available through 2023 as described above."

I have not yet seen this reporting from 2023 and am not aware if it has in fact been reported and

certified in 2023.

In summary, problems encountered in this January 2023 Geochemical Characterization Workplan include:

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross wants to proceed with Advanced Exploration.

- All that is available now is 96 rock core analyses according to the September 2023 Reclamation Summary (see below), which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". In any case, the 96 samples were not collected and analyzed as required under the Ontario Mining Act (see next bullet). Thus, Kinross Gold and WSP are guessing on how bad the contamination will be, but admit that some of it will be bad, and are likely years away from completing the ML-ARD work required under the Ontario Mining Act and its Regulation 240/00 (Mine Development and Closure under Part VII Of the Act).

- The stated approach and methodology used for Advanced Exploration is "based on the requirements" of two British Columbia documents from 1997-1998 (Price, 1998; Price and Errington, 1998; Price, Morin and Hutt, 1997). In reality, the Ontario Mining Act says the approach and methodology must be based on the 2009 federal Prediction Manual, not just as "guidance" as Great Bear has done. Thus, the work for Advanced Exploration to date does not meet the Ontario Mining Act through Regulation 240/00 and does not meet the 2009 federal ML-ARD Prediction Manual (Price, 2009).

- Even if this Geochemical Characterization Workplan was applicable and consistent with the 2009 federal ML-ARD Prediction Manual, such work requires at least 2 to 3 years to obtain all required information and interpretations. Thus, perhaps in 2025 or some year after there might be sufficient ML-ARD for Advanced Exploration, but not any time soon.

4. Great Bear Advanced Exploration Program Reclamation Strategy (September 2023)

The Introduction of this document explains:

> "This memorandum was prepared to summarize the reclamation strategy for the AEX [Advanced Exploration] Program. The regulatory Closure Plan which will be filed with the Ontario Ministry of Mines is currently being developed. The purpose of this memorandum is to seek input from Indigenous communities regarding the proposed closure strategy for the AEX Program."

Thus, this memo is only to "summarize" the reclamation strategy in order to "seek input from Indigenous communities". As shown below, this summary is insufficient for Grassy Narrows First Nation to provide input and this reclamation "summary" in fact already reveals errors and misconceptions.

Section 2 entitled Project Information lists "major components" for Advanced Exploration. For tonnages and sizes, only the ore is mentioned and it will be shipped offsite. So there is no overall summary of areas, volumes, and heights of waste and disturbed materials remaining on site and requiring careful reclamation. This is important, because there will be at least 17 tonnes of mine waste rock generated for each 1 tonne of ore (see Sections 2 and 10 of this MDAG review), which is a substantial ore:waste ratio and one that requires intensive efforts to protect the surrounding environment. There would also be ~7 tonnes of overburden mined for each 1 tonne of ore, which increased through 2023 from an initial ~3:1 ratio.

Therefore, this Reclamation Strategy does not sufficiently protect the environment due to the lack of sufficient data, which is replaced by information that at best "suggests". The decision to mine a huge bulk sample of ore worth tens of millions of dollars, likely to offset exploration costs, has not been based on suggestions, so why are associated reclamation and environmental protection based on suggestions?

There is no explanation in this or other documents on why an underground bulk sample requires the destruction of surface vegetation and shallow soils to remove a relatively enormous volume of 400,000 tonnes of overburden (the most recent estimate, which had been increasing). Additionally, 96 ML-ARD samples are mentioned for rock "proximal" to the underground workings, but there is no mention of the 30 samples of overburden also tested for ML-ARD potential.

Because roughly half of overburden stockpiles at sites similar to Great Bear have significant ML-ARD potential, the Great Bear overburden should be assumed to have the same strong potential for water contamination and ARD (called "PAG" in this document) unless proven otherwise. It is alarming that Kinross Gold is assuming 100% of the overburden is environmentally benign.

Figure 2 of this Reclamation Strategy shows an unlined overburden stockpile where its seepage can contaminate local water and soil, and Figure 3 shows the overburden runoff and seepage is completely ignored. This serious omission can also be seen in Section 2.3 which ignores contaminant potential from overburden by simply addressing surface runoff and not subsurface

seepage and groundwater:

> "Runoff from the overburden stockpiles (will be monitored and treated to manage suspended solids as required and discharged)"

Section 2.1 on Underground Mining Methods Summary does not describe advanced exploration where a bulk sample of several tonnes is obtained and tested. Instead, Section 2.1 describes an initial four-year phase of mining of more than 1 million tonnes of waste rock and 200,000 tonnes (more recently, ~400,000 t) of overburden to obtain only 60,000 tonnes of ore worth tens of millions of dollars. In reality, four years of this type of advanced exploration is essentially being used as the first phase of the underground mine plan so that there is relatively little delay to start mining should the project be approved.

In the Project Definition (see Section 2 of this MDAG review), Kinross Gold provided three reasons for a relatively huge bulk sample along with 17 times more waste rock and now 7 times more overburden. However, as explained above, these reasons do not make sense. For example, Kinross says that bulk samples help to prove the continuity of underground access gold deposits and are very important to potential financiers. Yet, most of the proposed underground workings are focussed into two small lateral areas and not throughout the ore zone "to prove the continuity".

In Section 2.2 on Geochemistry Summary, it says:

> "The sampling approach and testing methods for the preliminary geochemical assessment are based on the requirements described under the Ontario Mining Act, namely guidance found within the DRAFT Guidelines and Recommended Methods for the Prediction of Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (MEM 1998)."

This same error occurs in the January 2023 Geochemical Characterization Workplan. The Ontario Mining Act through its Regulation 240/00 does not mention the 1998 British Columbia document. Instead, the relevant wording is:

> "The sampling program shall be conducted by a person who is qualified in Ontario … in accordance with a report prepared by William A. Price on behalf of the [federal] Mine Environment Neutral Drainage (MEND) program, entitled "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials", MEND Report 1.20.1, dated December, 2009, as that report may be amended from time to time..."

Page P-24 of this 600-page federal Prediction Manual specified by the Ontario Regulation 240/00 says, "Major technical assistance was provided by Kevin Morin (Mine[site] Drainage Assessment Group)... and Kevin Morin provided major editorial assistance." Therefore, for the Great Bear Project, I can attest that "[t]he sampling approach and testing methods" are based on the wrong document.

Based on the 2009 federal Prediction Manual required by Regulation 240/00, the proposed ML-ARD work "in progress" is not sufficient, likely because the Manual was used by Kinross Gold only as "[a]dditional guidance" instead of a required document. This is easily seen in words like "preliminary geochemical assessment" and "initial evaluation". The ML-ARD predictions and information are the main basis for design of water treatment and for reclamation/closure. Thus, it is not acceptable for treatment and closure to be based on "preliminary" and "initial" information.

This can lead to misleading impact assessments and receiving-environment effects.

There are already errors in the Great Bear ML-ARD work as found in this Reclamation Strategy. These range from an incorrect definitions of the fundamental acronyms of "PAG" and "NPAG", to major problems with samples collected to date. For ML-ARD, all that is mentioned as of September 2023 is 96 rock-core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be mined during Advanced Exploration, but only "proximal" which could also mean "very different". Some percentage of this proximal rock, such as 50% to 67%, is considered not to have much ML-ARD potential based on "preliminary" data, but that is unreliable or wrong.

Kinross Gold is guessing on how bad the ML-ARD contamination will be, and admits some of it will be bad. However, it is likely years away from completing the appropriate ML-ARD work required under the Ontario Mining Act and Regulation 240/00, including the federal ML-ARD Prediction Manual (Price, 2009).

Section 2.4 of this Reclamation Strategy on Closure Objectives says:

> "The primary objective of closure is to rehabilitate the area to a long-term safe and sustainable state that considers the desires of local Indigenous land users to the extent practical (such as post closure land uses) by promoting vegetation communities that support habitat for local species diversity and aquatic habitat that will support healthy fish populations. The purpose of this memorandum is to seek input from indigenous communities regarding end land uses and closure concepts."

It is remarkable that Kinross Gold considers leaving "NPAG" rock perhaps with a cover of 0.3 m of potentially contaminated overburden, plus a large amount of stockpiled overburden at the surface, to be a "long-term safe and sustainable state...". To the contrary, this reclamation strategy can result in perpetual water treatment. A cover over "NPAG" rock does not stop ML and contaminated effluent, which could instead require perpetual water treatment. The closure plan and its estimated cost of only ~$10 million would not pay for this.

Section 3 on Progressive Rehabilitation Measures says:

> "Mine rock will be moved underground during the program as needed for use as road material, and potentially as backfill in underground areas for stability."

This issue arises later where "PAG" rock is proposed to be moved underground after mining of the bulk sample and the many underground workings. The seriously major problem here is that "PAG" rock can release relatively enormous amounts of heavy metals and other elements as it is flooded and submerged. This can create a toxic "soup" of underground water, worse than any seen at the surface, that eventually flows out into the surrounding environment and groundwater system. This would likely require long-term pump-and-treat remediation of the surrounding groundwater. Such pump-and-treat remediation is not included or costed in the ~$10 million total closure costs, and would likely cost much more than $10 million itself.

As part of closure, Section 5.1 says:

> "The portals will be backfilled with NPAG rockfill."

Because this rock will probably be an ML concern, including leaching heavy metals and other elements, backfilling the portals with this NPAG rock that will remain partially exposed and oxidizing will lead to perpetual ongoing water contamination. Adding to this contamination will be backfilled oxidized-and-contaminated PAG material that will likely release relatively large amounts of heavy metal and other elements. Contaminated water from this PAG material, backfilled into the underground workings and partially flooded to the maximum level, and from the NPAG material plugging the portals, would start flowing out of the mine area and into the surrounding groundwater system unless there is perpetual collection and treatment.

Section 5.6 on Soils Testing mistakenly says:

> "The primary soil contamination that could be expected from the AEX activities would result from the use / spillage of petroleum / diesel fuels. A soil sampling plan will be developed at the time of closure to evaluate potential hydrocarbon or chemical contamination, as appropriate."

In reality, the primary soil contamination would likely be from the elevated levels of heavy metals and other elements in wind-blown fugitive dust (see Section 8 of this MDAG review). This dust would come from the PAG and NPAG blasted-rock stockpiles, from the overburden stockpile(s), and from mine roads and building foundations made of the blasted rock and overburden.

Section 5.7 of this Reclamation Strategy says:

> "The primary long term closure concern with respect to the mine rock stockpiles is acid rock drainage and metals leaching. Preliminary geochemical investigations suggest that up to approximately 35% of the AEX mine rock could be PAG, as discussed in Section 2.2. During the AEX Program, the PAG and NPAG mine rock will be segregated in accordance with the AEX Mine Waste Management Plan, which is currently being developed at the time this document was prepared."

"Preliminary geochemical investigations suggest that..." is not acceptable for design of the waste-rock piles and the treatment system. Preliminary geochemical investigations can be seriously wrong and substantially underestimate contamination from the rock and overburden.

Section 5.7 also says:

> "It is anticipated that up to 127,200 m^3 of PAG mine rock will be stockpiled at the AEX Program and will need to be appropriately rehabilitated either progressively or at closure."

The closure costs from the Program Closure Plan (see Section 5 of this MDAG review below) show it will cost $30.00 per m^3 to relocate the PAG rock back into the underground workings, where it would then contaminate the underground water that will eventually flow into the environment. This would be a total cost of $3,816,000. However, Table 12-1 from the Program Closure Plan (issued two months after this Reclamation Strategy) estimates PAG rock higher at 191,000 m^3 (a remarkable 50% more) costing $5,730,000.

Section 5.7 also says:

> "The NPAG Stockpile footprint may be covered with up to 0.5 m of overburden and seeded for revegetation. Additional cover depth is provided overlying the NPAG Stockpile to account for potential losses to void spaces in the mine rock. It is anticipated that the overburden material will fill in the void spaces and support revegetation."

However, the overburden could have ML-ARD potential, and thus would not support vegetation but instead kill vegetation.

In summary of the Reclamation Strategy from September 2023,

- The ML-ARD program is "in progress" so no one knows how bad the contamination will be and which elements will be at toxic levels requiring treatment, yet Kinross Gold wants to proceed with Advanced Exploration.

- All that is available now is 96 core analyses, which on their own are not reliable and cannot yet be interpreted reliably for ML-ARD. In fact, these 96 samples were not even of the rock that would be "mined" during Advanced Exploration, but only "proximal" which could also mean "very different". Also, 30 samples of overburden, which is intended to be left on surface and used for reclamation, were collected yet the results are not reported although there is ~50% probability that the overburden will release ML-ARD and thus be toxic. Kinross Gold and WSP are guessing how bad the contamination will be, but admit that some of it will be bad. They are likely years away from completing the ML-ARD work required under the Ontario Mining Act and its Regulation 240/00, because the work for Great Bear was not initially stated as consistent with Regulation 240/00. Even the definitions of ML-ARD acronyms used for the Great Bear Project are not correct according to the federal Manual specified by Regulation 240/00, which is additional evidence the Prediction Manual is not being followed.

- The bad ML-ARD rock appears to be associated with "rapid acid generation" according to the Program Closure Plan (reviewed in the next section below). This is an incorrect explanation of the phenomenon, but shows that the bad water quality will start coming out of the disturbed rock, including the underground mine walls, very quickly after initial disturbance. Informally, this is called "lag time" to ML-ARD, but most of the ML-ARD work has not yet been done to quantitatively estimate the lag time beyond "rapid". This contaminating rock will be stored on surface and possibly only later, likely after the lag time, some might be taken underground. When it contacts water underground as the workings partially flood and submerge, it will quickly release more contamination. This means the underground water moving into the surrounding groundwater system, and surface overflow if any, would have to be monitored and likely be treated for many years or in perpetuity after Advanced Exploration.

5. Program Closure Plan, Draft for Indigenous Review (November 2023)

This password-protected draft document for Advanced Exploration is only "for Indigenous review". This is odd to me since it is Kinross Gold's responsibility to design and justify the closure plan through certified professionals, rather than submit a draft to see if any First Nations notice the weaknesses and problems explained below.

In fact, since this draft report it is password protected, none of its content can be extracted for detailed re-interpretation and review. Thus, Kinross Gold is limiting the "Indigenous review" it is seeking.

In Table 5-3 entitled Approximate Mine Rock and Overburden Volume and Production Schedule in Section 5.7 on Mineral Materials Management, the total waste rock remains around 1,060,000 t relative to past documents (see the sections of this MDAG review above).

However, overburden has risen remarkably from past documents to "~170,400 m^3", expressed as m^3 instead of tonnes like the waste rock. It would be ~350,000 to ~400,000 tonnes of overburden. The overburden's ML-ARD status and its impact on water quality are poorly defined. This means that overburden at Great Bear becomes an environmental danger capable of substantial environmental impacts not currently identified or estimated.

Table 5-4 contains Preliminary Threshold Criteria for Segregation the AEX Program Mine Rock. The criteria for "PAG" do not say whether the criteria are "AND" or "OR", which is a huge difference and serious omission. Thus, ML-ARD is clearly still not reliably estimated, predicted, and understood at the Great Bear Project as of November 2023.

The text in Section 5.7.2 alarmingly says,

> "A preliminary sulphur threshold (TS) of 0.15% has also been proposed to differentiate between PAG rock and NPAG rock. The proposed threshold values are generally accepted as industry best practices in the absence of a site specific geochemical value."

No, 0.15%S is not "industry best practices". Quebec uses ~0.05%S and other provinces have not established a minimum value because technically there is no minimum value. Furthermore, it is rarely the sulphur level alone that distinguishes "PAG" (incorrectly defined in this document as "potentially acid generating" and "NPAG" (incorrectly defined in this document as "non-potentially acid generating"). Instead, according to the federal ML-ARD Prediction Manual (Price, 2009), the amount of Effective Neutralization Potential (ENP) plays a major role, as does site-specific criteria for the ENP-to-sulphur ratio.

This is explained in detail in the 600-page federal ML-ARD Prediction Manual that this ML-ARD work for the Great Bear Project is legally supposed to follow but does not. As a result, this "preliminary sulphur threshold" is an unreliable, questionable, and uncertified attempt to proceed with the design and planning for Advanced Exploration. Insufficient reliable information is available at this time, and even Appendix A "Certifications" is missing from this document. As a professional

in ML-ARD, I want to know the certified professional(s) who created these "preliminary" criteria.

"NML" is defined in this Closure Plan as "non-metal leaching" which does not apply to any rock in the world, as all rock is capable of leaching some metals and even nonmetals. In any case, "NML" in Table 5-4 for the Great Bear Project is rarely definable by the solid-phase level of a single element like "Arsenic < 30 mg/kg", but Kinross Gold does not know this because it has not yet completed the on-site and laboratory-based kinetic tests. If leaching were dependent on solid-phase levels as believed here, then Great Bear waters would contain thousands of mg/L of aluminum and silica because most of its rock is made of those elements. But this is not the case. This is why these are called "preliminary threshold criteria" in Table 5-4, which in reality are likely wrong and nonsensical.

Section 9.16 on Watercourses and Site Drainage contains Tables 9-1 to 9-5. Tables 9-4 and 9-5 contain predictions of on-site and effluent contaminant levels only after closure, which would obviously be much less than during active exploration. However, the text does not even discuss or explain Tables 9-4 and 9-5. They appear to be "thrown in" to appear complete.

Table 9-4 contains Geochemical Source Terms, which are the predicted aqueous concentrations for all contaminants in Great Bear water caused by Advanced Exploration. In reality, there are many problems with this Table 9-4 including:

- It does not include "PAG" concentrations which will be much worse and will be present for at least four years, because this Table is intended only for closure but alarmingly does not include the likely more severe PAG contamination when it is backfilled into the underground workings.
- It assumes closure drainage from "Covered and Revegetated Area" will be instantaneously at pre-exploration "baseline water quality", which is wrong.
- It shows elements likely requiring perpetual post-closure treatment include aluminum, antimony, arsenic, and selenium.
- It does not include predictions for many potential contaminants such as manganese, magnesium, sodium, potassium, barium, hardness, alkalinity, acidity, fluoride, chloride, bismuth, chromium 6+, lithium, silicon, strontium, tellurium, thorium, tin, titanium, and zirconium.
- It does not allow for federal emerging contaminants such as platinum-group metals and tantalum.
- It is based on a report "WSP 2023f" which is the draft "WSP, 2023f. Advanced Exploration (AEX) Phase – Preliminary Water Quality Estimate Update - Draft. WSP E&I Limited, April 2023". This report is only draft and thus is unreliable and not professionally certified.

Table 9-5 contains Mine Water Pond Overflow Estimated Water Quality which apparently would be overflow off the exploration site upon closure. It raises important questions, like how does aqueous sulphate decrease from 75-100 mg/L (Table 9-4) to 18-25 mg/L (Table 9-5) in mine-water-pond overflow when there is no treatment? In any case, some predicted concentrations are likely too high to discharge to the environment like arsenic. Also, sulphate reportedly increases the methylation of mercury and other elements.

Table 12-1 is the Closure Cost Estimate. The cost for moving PAG rock back underground is set at $30.00/m^3 which is ~$15.00 /tonne. The total waste rock from Advanced Exploration is estimated at 1,060,000 t. Kinross Gold currently guesses, based on preliminary uncertified information, the waste rock will be about one-third to one-half "PAG" requiring backfilling to the underground. Therefore, the cost for this task alone is $5,000,000 to $7,500,000 based on the unverified guess, and could reach a maximum of $15,000,000. Because the current Grand Total for Closure is estimated at ~$10,000,000, the backfilling of rock is the major cost item and could cost much more than the $5,730,000 currently estimated. In turn, Total Cost could cost many millions of dollars more than currently estimated from the guessed minimal amount. Put simply, closure costs are likely grossly underestimated.

All six appendices of this Program Closure Plan are missing, including professional certifications. This is likely not an error or oversight, meaning this Program Closure Plan should not be considered reliable and dependable.

In summary of the password-protected Program Closure Plan, Draft for Indigenous Review from November 2023,

- In November 2023, the volume of overburden has approximately doubled from previous documents without an explanation. Because overburden generally has a 50% probability of releasing ML-ARD and contaminating water, overburden represents a major but unexamined threat to water quality on, around, and beneath the Great Bear exploration site.

- "Preliminary" criteria are provided for separating "PAG" and "NPAG" rock and for "NML" rock. However, these acronyms are not used in an accurate manner consistent with the 2009 federal Prediction Manual (Price, 2009) required under Regulation 240/00. The preliminary criteria are not rational based on ML-ARD science unless justified with detailed and intensive site-specific studies, which have not yet been completed and certified for the Great Bear Project.

- The potential for ML-ARD after closure is presented all the way to detailed predictions of aqueous concentrations in mg/L for on-site water and effluent to the environment only after closure. However, these predictions are not explained in any detail, are not justified, appear anomalous, and are not certified by a qualified professional. Some predictions are actually pre-exploration baseline which are erroneously assumed to be re-established immediately at closure. Furthermore, these predictions are missing more than a dozen potential contaminants.

- The "PAG" rock, which would likely create the highest contaminant concentrations, is not included in this Program Closure Plan, presumably because this "PAG" rock will be backfilled underground. However, when placed underground, this "PAG" rock will likely continue to release severe ML-ARD until submerged, at which point a relatively huge amount of accumulated contamination would be released into the underground water. After the mine is refilled to equilibrium and the minewater begins flowing into the surrounding groundwater system and through the many permeable drillholes more than 500 km long to the

environment, it will contaminate large surrounding areas. This major risk to water quality and the environment is not even mentioned in this Closure Plan, which is a major omission.

- The backfilling of "PAG" rock at closure is the largest individual cost item for closure totalling around $10 million. However, this reflects the currently minimum volume based on preliminary, unreliable information. In the worst case, which was assumed for the Great Bear Project Definition and still not disproven, total closure costs could exceed $20 million.

6. Hydrogeological Workplan (December 21, 2022)

This Workplan for 2023 says:

> "The purpose of the program will be to develop a refined hydrogeological model of the site, support groundwater model calibration and be used for long-term monitoring. The information collected in the upcoming field surveys will supplement the existing information.... Hydrogeological testing and groundwater sampling will occur at specific locations near the Project site shown in Figure 1."

However, Figure 1 of the Hydrogeologic Workplan shows a major omission which would preclude fully meeting its purpose and objectives. The currently proposed mine plan shows the "Tailings Management Facility" extending at least 2 km to the west and northwest of Tear Drop Lake. Figure 1 shows that the Tailings Management Facility and its hydrogeologic effects would extend far beyond the western limit of the monitoring wells. Thus, many more monitor wells are needed westward and northward at least to Stone Lake, Gullrock Lake, and Genessee Lake.

In summary of this Hydrogeological Workplan from December 2022, there is a major omission that would preclude a reliable and comprehensive assessment of current baseline hydrogeologic conditions and of future impacts from proposed mining. The groundwater monitoring network does not extend far enough to the west and northwest, beyond the proposed western portion of the Tailings Management Facility.

7. Surface Water Quality Workplan (December 21, 2022)

This Workplan for 2023says:

> "Baseline surface water quality work has been ongoing for the proposed Great Bear Project (the Project) since 2020. This proposed workplan for 2023 is to gather supplemental water quality data that will be used to further support long term monitoring and the development of the Project."

This Surface Water Quality Workplan provides incomplete lists of important details prefaced by "including", like "These sampling locations include..." and "Standard suite of total and dissolved metals including...". This can lead to major problems in the future if a sampling location or water-quality parameter is missing.

For example, the "Standard suite of total and dissolved metals including..." does not mention important elements like manganese, titanium, thallium, and federal emerging elements like tantalum and platinum-group elements. Therefore, Kinross Gold is risking major omissions and flaws that can arise later by not being comprehensive in its "including" lists.

In summary of this Surface Water Quality Workplan from December 2022, there are insufficient information and details to determine if appropriate work is planned and conducted. This is because important details are listed only as "including". For example, major potential contaminants like manganese and thallium are not specifically listed, but perhaps they are implicitly included? There is no way to know.

8. Fugitive Dust Best Management Practices Plan, final draft (September 2023)

Section 4.5 on Material Stockpiles in this "Final Draft" states there will be two overburden stockpiles created during Advanced Exploration, one north of the mine-rock pile and another east of the crusher area. Some Great Bear documents reviewed above and the undated "AEX Site Plan - Updated.pdf" do not show this. Because the overburden has a general 50% probability of contaminating water and because overburden is specifically listed as a site component requiring ML-ARD evaluation and potential mitigation, this contradiction on overburden stockpiles is not acceptable. It further shows that Kinross Gold's ongoing issuing of "preliminary", "initial, and "draft" documents is causing confusion inside the project itself and thus should not be approved at this time.

Section 5.1 on the Composition and Characterization of Particulate Emissions contains a major error that would grossly underestimate the geochemical contamination of soil, vegetation, water, and biota by dust, and is thus not acceptable. Section 5.1 says:

> "Fugitive dusts from roadways and stockpiles may contain trace metals which may be considered negligible as these would be similar in concentration to the background rock."

The ML-ARD studies currently underway on ore, waste rock, and overburden have already shown that some material will contain substantial solid-phase levels of many elements and will leach to some degree. This is certainly not "background rock" as assumed in this fugitive-dust study. Therefore, fugitive dust should be an important component of impact assessment for Advanced Exploration and proposed mining.

Furthermore, proposed dust suppression by watering could lead to widespread metal leaching and water-quality degradation across and around the proposed exploration site.

In summary of the final-draft Fugitive Dust Best Management Practices Plan of September 2023 for Advanced Exploration, this work is unacceptable because it grossly underestimates the potential impacts from geochemical contamination of soil, vegetation, water, and biota by dust. This work assumes the on-site sources of dust "would be similar in concentration to the background rock". This is wrong and ignores the ongoing ML-ARD assessment of ore, rock, and overburden.

9. PTTW Application for Dewatering, final draft (October 2023)

This is one of the few Great Bear documents that provide names for the qualified person writing the report, appropriately signed as "DRAFT" at this time. However, the reviewer but not the author is a P. Geo. So additional information is needed on the qualifications and certifications of the author(s). PPTW stands for "Permit To Take Water", meaning using and removing water from the Great Bear site.

9.1 Main Report

The tone of this "final draft" report for Advanced Exploration is apparent from Section 1.1 on the Purpose and Scope of This Submission. It says:
"Water takings during the AEX Program will include:

- Water pumped from the underground exploration workings (underground dewatering)
- Incidental surface water and groundwater takings, expected to occur during excavation of water management ponds.
- Direct taking from Dixie Creek (up to 250 cubic metres per day; m^3/day) to be used for dust suppression, industrial activity (e.g. in support of development pad construction and packing) and advanced exploration drill water cooling (underground drilling).

"No other takings from other area waterbodies (lakes, rivers, streams) are proposed.

"Most of the dewatering water pumped from the underground exploration workings will be directed to ponds within the AEX water management system, treated and ultimately discharged to the environment to be approved under an Environmental Compliance Approval for Industrial Sewage Works (ECA ISW)"

First, note that the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning that the actual total water withdrawal from the local water balance, as shown in Table 4-1 (discussed below), would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these values are unrealistically low (see Section 9.2 below). This major withdrawal of water, that could upset and dewater groundwater zones like aquifers and surface waterbodies like creeks and lakes, is much more extreme that numerically indicated in Section 1.1. This justifies an impact assessment on the proposed Advanced Exploration, despite this final-draft document stating:

> "The AEX Program does not meet the requirements of the Impact Assessment Act, Physical Activities Regulations. A Federal Impact Assessment is therefore not anticipated to be required."

Second, note that the quotation above states that water taken from Dixie Creek would be used for "dust suppression" among others. As explained in the previous Section 8 of this MDAG review, adding such water to ML-ARD dust from ore, rock, and overburden could seriously degrade water quality throughout the site and surrounding environment. However, this major environmental risk

is not considered or even mentioned here or in the fugitive-dust study. In fact, it is unreliably assumed to be no environmental risk at all.

Third, the discharge of up to 7,703,000 L/day of water that is only partially treated (see the details in other sections of this MDAG review like Sections 5 and 11) into any receiving environment could cause significant impacts from (1) the physical volume of the additional water and/or (2) its altered chemistry from baseline with implications on the receiving environment and cumulative effects.

Table 4-1 on Requested Water Takings shows that the requested surface-water withdrawal from Dixie Creek is 250,000 L/day and an additional 170,000 L/day from pond excavations. However, more than 10 times this amount will be removed from the groundwater system every day. The additional groundwater withdrawal is estimated at 783,000 L/day from pond excavations, 2,000,000 L/day from underground pumping, and on perhaps 30 days each year an additional 4,500,000 L/day removed as a contingency. Furthermore, as explained below for Appendix B of this PTTW document (see Section 9.2 of this MDAG review), the groundwater model incorrectly underestimates the much higher inflows that would arise during desaturation of the overburden and the rock surrounding the mine inside its "Zone of Influence".

Total water withdrawal from the existing water balance could thus likely be much more than 7,703,000 L/day relative to the Dixie Creek withdrawal of only 250,000 L/day. All this water would be taken from the existing baseline groundwater/surface-water balance which has likely reached some type of baseline equilibrium over the last thousands of years. When up to 7,703,000 L/day or more is removed from this equilibrium, there could be major disruptions to local and regional surface waters and groundwaters.

For example, a significant portion of the underground pumping of more than 6,500,000 L/day could be pulled from Dixie Creek through the underlying groundwater system. Thus, "takings" from Dixie Creek could in reality be 250,000 L/day plus substantially much more than this through groundwater. "Takings" could also come from other streams, lakes, and groundwater zones like aquifers, despite this report clearly stating, "No other takings from other area waterbodies (lakes, rivers, streams) are proposed". This statement is not reliable and could be seriously wrong.

Section 5 of this PTTW Application discusses Potential Environmental Impacts, with Section 5.2.1 specifically on Dixie Creek. There appears to be significant confusion here on the impacts of dewatering the underground workings on Dixie Creek.

Part of this confusion arises in the false thinking that baseflow coming from groundwater is simply part of the total flow in Dixie Creek. In reality, groundwater baseflow likely has a different, more stable temperature and a different water quality than the surface water flowing past the Great Bear Project. Therefore, it is important environmentally and to the benthic ecosystem to consider baseflow coming from groundwater separately from surface flow already in the creek.

Another part of this confusion on the physical impact of mine dewatering on Dixie Creek is related to which surface flow is used. Section 5.2.1 uses Average Annual Flow, Low Flow Period Average Flow (March), and Low Flow 7Q20. These show that mine dewatering will reduce flow in Dixie

Creek by only 0.2 to 2.4%. Again, these impacts would be greater because the groundwater of Appendix B (see Section 9.2 below) has underestimated the amount of underground water that has to be pumped.

Table 5-2 is more relevant for Dixie Creek, also copied as Table 7-2 in Appendix B. It shows the important, separate baseline baseflow for Dixie Creek is 2,601,000 L/day. This is predicted to be reduced by 873,000 L/day during dewatering for Advanced Exploration, although this is likely substantially underestimated by the groundwater model. Thus, much more than 34% of Dixie Creek baseflow will be taken away by the mine, which would have significant adverse effects during drought periods and on the quality of the benthic aquatic habitat. Additionally, the baseflow for Unnamed Waterbody 3 (called "Dixie Creek Tributary (TL-3)" in Appendix B) would be reduced a substantial 55%. This justifies an impact assessment for the proposed PTTW Application.

It is very important to note that this PTTW Application for Dewatering, final draft, contains and is based on critical information in its Appendices. The following comments pertain to these appendices, which in turn shows the main report is not reliable and not reasonable as a PTTW Application.

9.2 Appendix B

Appendix B of this PTTW report is a "Draft" Groundwater Modelling Report to Support PPTW Application for Underground Dewatering Final Draft. It contains a serious error in the groundwater modelling that underestimates initial groundwater inflow rates and thus dewatering pumping rates.

Table 4-1 of the main report says 3,203,000 L/day of groundwater would be removed every day, reaching up to 7,703,000 L/day on some days. Table 6-2 of this groundwater appendix says that the groundwater grid, from Genessee Lake on the west to half of Rice Lake to the east, has total groundwater inflows and outflows of ~10,000,000 L/day. If this modelling were correct, this means that roughly 32% of all groundwater in the area of the Great Bear Project will be drawn into and out of the mine on a daily basis, with up to 77% drawn into and out of the mine on some days as a contingency. However, it could well be worse as explained next. This justifies an impact assessment for the proposed PTTW Application.

If dewatering starts and continues for several years as proposed for Advanced Exploration at the Great Bear Project, and later during the expansion of proposed mining, groundwater inflow will come from two basic sources. The first, initial inflow will predominantly reflect the desaturating drainage of pores in the overburden and fractures in the rock, which will be relatively high at first and then decrease. Notably, the modelling currently shows that the overburden will eventually be virtually 100% dewatered to its base. This is called "transient conditions" and reflects the "specific yield" of the overburden and the "storage coefficient" of the rock. As this first transient inflow slows, likely years after Advanced Exploration ceases, the groundwater inflow will then come from "steady state", reflecting the hydraulic gradients and the hydraulic conductivities.

This modelling for Great Bear in Appendix B and for the PTTW Application is solely "steady state",

with no high transient inflow considered and no values for specific yields and storage coefficients even mentioned. Section 6 of Appendix B on Groundwater Model Development is clear on this:

> "Groundwater modelling was conducted for two phases: pre-mining site conditions for model calibration and mine operations conditions to predict *groundwater discharge rate to the proposed fully developed and dewatered underground mine workings* [MDAG emphasis]. These numerical groundwater flow models consider 3D *steady-state flow conditions* [MDAG emphasis] and implement an Equivalent Porous Media (EPM) approach, which is deemed sufficient for characterizing the overall groundwater flow regime at the scale of this analysis."

Thus, groundwater inflows in the years of active mining during Advanced Exploration have been clearly underestimated by considering only steady-state inflows after the proposed workings are "fully developed". Also note the ambiguous and unjustified "deemed sufficient" for the overall "EPM" modelling of groundwater at the Great Bear Project.

Table 6-3 showed that pre-mining single-value "measured interpreted" baseflows at two locations agreed with the Simulated Baseflow reflecting only long-term steady-state conditions by 14% or better. These single-value baseflows were 2,281,000 L/day and 847,000 L/day, which are less than the total groundwater that would be pumped from the mine during Advanced Exploration. Thus, a concern arises on whether baseflows could be significantly decreased by this pumping during Advanced Exploration. The main report (see comments above in Section 9.1 of this MDAG review) says the (underestimated) pumping effect would be minimal on most statistical values of flow in Dixie Creek. It is not emphasized that pumping would substantially reduce baseflow, with differing water quality and temperature than the surface water, and would be even more significant during droughts.

Figure 6-6 shows that the pre-mining Simulated Groundwater Levels were often 5 to 10 m higher than Observed Groundwater Levels, showing a strong bias towards overestimated (higher) simulated groundwater levels. It is not clear if this suggests simulated hydraulic conductivities may be too low. In any case, this problem manifests in Figure 6-7 where the simulated levels around Great Bear and Dixie Creek are typically around 9 m too high, which incorrectly and falsely indicate Dixie Creek could not be significantly dewatered during pumping because the water table is simulated to be very high. This is probably why Table 7-2 shows that the substantial yet likely underestimated partial dewatering of Dixie Creek Tributary (TL-3) and baseflow of Dixie Creek is 55% and 34%, respectively, and these dewatering percentages could be much higher if modelling were more accurate.

Of note, Table 7-1 indicates dewatering of Dixie Creek is only 1% because it uses the average annual flow that includes the sum of all storm events. It does not consider lost baseflow during dry times when aquatic life, vegetation, and water quality can be more severely degraded. Again, the simulated groundwater levels around Dixie Creek and Great Bear are often modelled around 9 m too high and thus actual dewatering of creeks and lakes could be much higher than stated in this groundwater report. In this case, Section 10 incorrectly states and underestimates based on the modelling that:

> "At the end of the AEX project, when dewatering is at its maximum, the model simulates a baseflow reduction for the Dixie Creek of 8.5% of the estimated 7Q20 (10,368 m^3/d) and 1% of the average annual flow (114,912 m^3/d), which is unlikely to change the nature of the flow

regime in the creeks."

In Section 7.1 on Groundwater Inflow Rate and Zone of Influence:

> "... the simulated long-term groundwater inflow rate into underground mine workings is 1,920 m^3/d [1,920,000 L/day]. This estimate of groundwater inflow into the fully developed mine does not consider uncertainty, seasonal variations or any loss from aquifer storage."

This simulated inflow is consistent with the estimated 2,000,000 L/day requested "taking" in the main report and in Table 8-1. However, the occasional contingency of 6,500,000 L/day which is apparently from "uncertainty, seasonal variations or any loss from aquifer storage" is relatively major. It highlights the expected variability of withdrawals and discharges of water into the surrounding environment during Advanced Exploration. Moreover, the reference to "aquifer storage" highlights the failure of the modelling to consider higher-inflow transient conditions which would be most important in the early several years of Advanced Exploration.

However, even ignoring the important high-flow transient conditions, Table 7-1 shows that the steady-state 2,000,000 L/day can be easily exceeded by non-base-case conditions like three-times-higher hydraulic conductivity of bedrock and by the water-conducting LP Shear Fault 1.

Section 7.1 explains:

> "The model-predicted Zone Of Influence (ZOI), defined here as 1 m drawdown of head in the glacial till unit is shown in Figure 7-1. The ZOI is predicted to extend about 1.2 to 2.5 km from the centre of the AEX site to surrounding environs."

Using the 1 m drawdown contour is not appropriate here, because modelled groundwater levels are already around 9 m too high and because Figures 4-9 and 4-12 show that some shallow groundwater levels can vary by 1 m naturally. Thus, the Zone of Influence could turn out to be much larger and thus affect lakes and creeks. In any case, even a 1 m decrease in groundwater level beneath a creek or lake can lead to substantial dewatering.

Figure 7-1 shows Simulated Drawdown Contours in Glacial Till. However, drawdown is only shown as a maximum of around 36 m, which is obviously not correct for dewatered drifts up to 600 m deep. Moreover, the maximum drawdown of 36 m in the overburden means most of the pores of the overburden would be primarily drained into the mine, which occurs during the ignored transient conditions.

The apparent explanation for the discrepancy between the maximum 36 m drawdown and the dewatered workings 600 m deep is that the drawdown in the bedrock is not shown, but would locally obviously be around 600 m. This 600-m drawdown would likely create a relatively huge drawdown zone in bedrock around the Advanced Exploration and the proposed mine extending for many kilometers around. This would be much larger than in the Zone of Influence in the overburden shown in Appendix B Figure 7-1. This justifies an impact assessment of this proposed dewatering since many impacts of the dewatering have been ignored or underestimated.

9.3 Appendix C and Its Several Draft Monitoring Programs

Appendix C contains draft monitoring programs. The "Working Draft" AEX ISW Groundwater Monitoring Plan, like many other Great Bear documents, ignores the overburden that likely has ML-ARD potential and can seriously contaminate water. This lack of consideration for potentially contaminating overburden can be seen in Figure 1-7 Water Management Schematic that has no mention or recognition of the overburden stockpile(s). The same is noted in Figure 1-6 of both the "Draft" ECA ISW - Advanced Exploration Surface Water Monitoring Plan Draft and the "draft" AEX ECA ISW Aquatic Resources Monitoring Plan in Appendix C.

9.4 Appendix D

Appendix D Consultation Records is missing from this file.

9.5 Summary

In summary of this PTTW (Permit To Take Water) Application for Dewatering, Final Draft, and its several important appendices from October 2023, there are alarming errors and ambiguities that should preclude approval of PTTW. These should also trigger a detailed impact assessment, which this PTTW report conversely says is not needed for Advanced Exploration at Great Bear.

In the introduction to the main PTTW report, the only numerical water withdrawal mentioned is up to 250 m^3/day (250,000 L/day) from Dixie Creek. Thus, it is stunning because the actual total water withdrawal from the local groundwater/surface-water balance would be at least 3,203,000 L/day every day and reaching up to 7,703,000 L/day on some days as a contingency. Even these values are unrealistically low as explained here.

The errors begin with groundwater modelling that is based on long-term "steady state conditions" after the mine is "fully developed" and dewatered, and not on the correct, higher-inflow "transient conditions". Thus, inflow, pumping, and dewatering are significantly underestimated by the groundwater model and the PTTW Application. Additionally, there are problems with unrealistically low estimated effects on partial dewatering of Dixie Creek and other creeks and rivers. For example, simulated groundwater levels are modelled around 9 m higher than measured around the mine and Dixie Creek, which artificially and incorrectly prevent additional dewatering of Dixie Creek.

Groundwater levels are shown to be drawn down during dewatering to a maximum of only 36 m even though the dewatered workings will be 600 m deep. This reflects (1) nearly fully dewatering of the shallow overburden and (2) the lack of admission on the likely huge drawdown and much larger "Zone of Influence" in the rock beneath the overburden.

Baseflows into Dixie Creek and other waterbodies can be critical to aquatic, benthic, and terrestrial ecosystems because of groundwater's typically different water quality and temperature compared to water already flowing at the surface. This becomes more critical during droughts when baseflow

may be the main source of surface flows. The PTTW Application ignores the fact that more than 34 to 55% of existing baseflow would be lost during Advanced Exploration. It instead points out that the loss to groundwater would be only 2.4% and less of total flow depending on the chosen surface-flow statistic.

Overburden is routinely ignored in this PTTW document and its appendices, despite the proposed hundreds of thousands of tonnes of overburden likely having at least some ML-ARD potential and capacity to degrade water quality. In fact, some of the underground dewatering would be sprayed on the overburden for dust suppression, which in turn could lead to contaminated runoff across and off the site.

10. Draft (?) Detailed Project Description (November 2023)

In June 2023, Kinross Gold released the [final] Initial Project Description for the Great Bear Gold Project. Five months later, Kinross Gold issued the Detailed Project Description, where the first cover page showing "Kinross" says "DRAFT", but the second cover page for WSP E&I Canada Limited does not say "Draft".

The Kinross/WSP documents reviewed so far for proposed exploration and proposed mining are a mess with confusions over draft, preliminary, initial, and final. There is no reliable way to know what information issued by WSP and Kinross is considered final, reliable, and still applicable. In my opinion, all reviews for Great Bear should stop until Kinross Gold and WSP identify the final designs and plans for proposed exploration and proposed mining. Only then should they issue the final documents, signed and approved by qualified professionals.

Because the Initial Project Description was followed five months later by this perhaps-draft-perhaps-not-draft Detailed Project Description that apparently includes responses to Initial concerns, only the latter document is reviewed here.

10.1 Section C.3.3 Proposed Mine Facilities and Infrastructure

Section C.3.3 and Table C.1 provide a detailed list of all proposed mine facilities, many of which would be created during Advanced Exploration, which as explained above is closer to a first phase of mining. Many of the listed facilities require ML-ARD assessment including all under the headings of Underground and Open Pit Mine including mine walls and sumps, Stockpiles including overburden and waste rock, Tailings and Site Water Management including ditches, Aggregate Supply, Waste Management, Fuels and Reagents, all access roads and haul roads, all excavations and foundations for buildings, facilities, pipeline corridors, upgrades to bridge crossings, and the core shack including core-storage areas. Because these ML-ARD assessments are not completed at this time, it is prudent to conduct an impact assessment on all these components.

The Stockpiles section says:

> "Stockpiles will be created on the surface near the mine to store ore, mine rock, and overburden / organics resulting from site and mine development. Preliminary storage capacities of the stockpiles for the Project are the following, subject to revision as a result of ongoing exploration and technical studies:
>
> - Run of mine (i.e., uncrushed rock as transported from the mine) ore stockpile: approximately 0.1 to 0.5 million tonnes (Mt)
> - Low grade ore stockpile: approximately 5 to 20 Mt
> - Mine rock stockpile(s): approximately 210 Mt
> - Overburden / organics stockpile: approximately 40 Mt."

Thus, upon full mining, there would hundreds of millions of tonnes of mine waste, with most of it likely remaining on the surface and requiring perpetual maintenance. Additionally, low-grade ore

stockpiles are sometimes left on site after closure as waste-rock dumps. Because of this, some jurisdictions require financial assurances on perpetual maintenance of the low-grade dumps until/if they are processed. This should also be done for the Great Bear Project.

> " Based on the scale of the stockpiles and the environmental baseline studies which are in progress, it is expected that one or more of the Project stockpiles will overprint minor creeks which may contain fish."

Thus, there will be "overprint" impacts through destruction of fish, fish habitat, and associated water quality.

The Ore Processing section says:

> "Ore processing will entail several stages of conventional mineral processing such as grinding and classification, and cyanide leaching to separate the gold / silver from the gangue leading to production of doré bars."

Thus, the processing will add contaminants including cyanide and accelerated leaching of metals and other elements that will contaminate the water in the process, in the tailings impoundment, and in the fugitive seepage that will flow into the environment.

Also:

> "There are no sources of mercury from the ore processing."

This appears impossible because the ore rock going in, and the tailings and concentrate coming out, of ore processing should and will contain some level of mercury. The processing could even increase the solubility or leaching rate of mercury and other elements. Therefore, this appears to be an error unless Kinross Gold can prove the tailings and concentrate from the ore processing contain absolutely no mercury. This is highly unlikely if not impossible to prove.

The section on Tailings Management explains:

> "The primary by-product of ore processing is tailings. Tailings consist of ground rock and associated process effluents that result from the processing of ore. Tailings will be treated for cyanide destruction before storage. As part of the ongoing geochemistry investigations it was determined that the tailings may be potentially acid generating, Kinross is investigating the potential to desulphurize the initial tailings stream resulting in a non acid generating flotation tailings, and a smaller quantity of sulphide tailings that would be managed in a manner to mitigate their acid generating potential."

Cyanide destruction is rarely perfect and sometimes simply converts the cyanide to thiocyanide or cyanate which can then revert to cyanide after release to the environment. Because the details of Great Bear's cyanide destruction are not given, it is prudent to assess it for potential environmental impacts.

Tailings Management further says:

> "Tailings will be transferred from the processing plant to an onsite surface management facility as a slurry, or potentially as a filtered cake. A quantity of the tailings will also be sent to a paste backfill plant where they will be mixed with a binder (such as cement) to increase their strength, so that they can be returned to the underground workings to provide additional underground stability. Tailings could also potentially be stored in the open pit after mining

is complete.

Tailings paste backfill, dewatered filter-cake tailings, and the relocation and in-pit disposal of tailings each could have unique adverse impacts on water quality and this should be assessed by Kinross Gold.

> "Further detail on tailings management facility, including dam designs as applicable, will be developed as engineering progresses for the Project. The facility will be designed in accordance with all regulatory requirements including the Canadian Dam Association Dam Safety Guidelines as applicable."

Thus, the details for evaluating potential environmental impacts will not be available until "engineering progresses", which is consistent with the ML-ARD work which will not be completed for at least a few years.

Notably, this section on Tailings Management has no detailed description of water management including any water recirculation. This is a major omission that precludes a reliable assessment of impacts from how much water would be needed daily to run this proposed mine.

The section on Buildings and Yard Areas states:

"The following new permanent facilities are planned for the Project:

- Process plant and crusher / conveying system
- Mine office / dry / maintenance / wash bay complex
- Cold and warm storage buildings
- Reagent storage facilities
- General laydown areas and parking
- Additional core shack, laboratory and outbuildings
- Accommodations / camp
- Explosives storage facilities.

These will be supported by related road, piping and power infrastructure as needed."

The disturbed rock or overburden used in any of these Areas requires an ML-ARD assessment as explained in the 2009 federal ML-ARD Prediction Manual (Price, 2009).

The section on Water Management Facilities and Drainage Works explains:

> "Kinross proposes to establish an integrated water management system for the site to manage contact water from the underground mine, open pits and surface facilities. The underground mine will intercept groundwater, while the open pit will collect groundwater, runoff and direct precipitation. Mine water from the required dewatering of the underground mine and open pit, to enable mining to occur will be collected in sumps and pumped to the surface for additional management. The mine water management and treatment infrastructure developed for the AEX program is expected to be re-used at the beginning of operations and will potentially be incorporated into the overall integrated water management system for the operating mine.
>
> "Precipitation and surface runoff that comes into contact with mine-related facilities on surface will be collected in ditches and collection ponds designed. As needed, the water will be directed to the integrated water management system for treatment and discharge with

other site contact water.

> "The integrated water management system and associated effluent treatment plant will be designed and operated to ensure that effluent from the site meets all regulatory requirements and can be discharged to the environment. Effluent will be discharged to the Chukuni River a large watercourse with high assimilative capacity. This will allow continued use of the pipeline corridor established for the AEX program. The additional infrastructure required for the mine has not yet been determined."

This section on Water Management Facilities and Drainage Works does not explain the storm return periods for which the drainage works would be sized. Nor does it specify the design return period for the post-closure water management, such as the 24-hour 1-in-200-year precipitation or the Probable Maximum Flood. This is a major omission that precludes a reliable assessment of impacts from storm events that could lead to spills of contaminated site water, and thus confuses the decision on whether an impact assessment should be conducted.

Under Access and Site Roads:

> "A network of roads of will be established within the site as needed, minimizing water crossings. New roads will be constructed of aggregate or non-potentially acid generating mine rock. New major road and watercourse crossings are not expected for the Project, although minor crossings and cross drainages may be needed. The water pipeline corridor which will be developed for the AEX program, and potentially expanded with additional pipelines for the mine, includes an access road to allow for pipeline inspections, environmental monitoring and maintenance, and is expected to cross four headwater creeks / low-lying swales, likely as culverts (Figure C.1 and Figure C.2). The existing prefabricated truss bridge across Dixie Creek may be upgraded."

Any surface and subsurface disturbance including new roads require ML-ARD assessments before an impact assessment can be done according to the 2009 federal ML-ARD Prediction Manual (Price, 2009).

The Section on Aggregate Operations contains a serious error:

> "Aggregate will be required to develop the Project. The primary source of material is proposed to be *nonreactive mine rock and overburden* [MDAG emphasis] from stripping and other construction activities within the site. There are licensed commercial aggregate pits nearby (along Tuzyk's Road) that also represent a potential source of aggregate for the Project. Discussions with the owners of these aggregate facilities are planned to explore potential commercial arrangements.
>
> "New quarries for crushed rock and sand and gravel pits may be established on the Property if needed under the care and control of Kinross. Locations are not as yet known but may be situated at future development locations (such as within the tailing management area)."

Because there is no such thing as "nonreactive mine rock and overburden", then there will be no aggregate which is "required to develop the Project", which in turn literally means there can be no Great Bear Project or mine. This illustrates how Kinross Gold is submitting perhaps-draft

documents with statements intended to alleviate concerns that are instead false and misleading.

This document is not signed and certified by Qualified Professionals, so at least portions of this Detailed Project Description are more akin to Public Relations than technical accuracy. Grassy Narrows First Nation should be aware of these false statements in important documents supposed to describe accurately and reliably the proposed exploration and proposed mining of the Great Bear site. It is not prudent to decide impacts of proposed exploration and mining based on false technical statements.

10.2 Section C.3.4 Preliminary List of Mine Activities

This section C.3.4 lists many "preliminary" activities during Construction, Operations, and Decommissioning and Closure. While many sound like generally good ideas, they can turn out to be bad ideas and not even possible at the Great Bear Project.

For example, here are some "preliminary" activities:

> "Overburden and organic material from the open pits will be either stockpiled or used for progression reclamation"
>
> "Mine rock extracted from the underground workings and open pits will be stockpiled, re-used as aggregate, or potentially re-used a consolidated rockfill underground"

The Project Definition Document of December 2022 assumed all the mine rock would have strong ML-ARD potential and would substantially contaminate water. Overburden was not even assessed although required by Ontario Regulation 240/00. It is understandable that the initial worst-case scenario may be modified as years go by and as ML-ARD studies are completed according to the 2009 federal ML-ARD Prediction Manual. However, there may be little change from the worst case at the Great Bear Project, but no one knows at this time. Thus, these "preliminary" activities can cause wider and worse impacts; no one knows at this time. Nevertheless, this perhaps-draft Detailed Project Description lists them anyway without pointing out their potential for adverse impacts.

This section also says,

> "As operations continue the open pit will have a progressively larger surface area and will become deeper"

The proposed pits are a concern to me as I do not see them justified by Kinross Gold. In fact, Figure C.5 shows that most of proposed pits and excavations are not needed to access most of the ore. Thus, there seems to be another, unstated reason for them, but I cannot see what it is.

10.3 Section C.3.5 Preliminary Decommission Approach

This section says:

> "Decommissioning and final closure of the Project site will be governed by the Ontario Mining Act, and its associated Regulations and Codes, and will be informed by ongoing engagement with Indigenous Nations and potentially affected stakeholders. The Act requires

> that a Closure Plan be filed for mining project before construction, and that financial assurance be provided so sufficient funds are in place to carry out the decommissioning activities.
>
> "A preliminary description of the proposed decommissioning and reclamation measures is provided in the text that follows. The preliminary measures are subject to consultation, additional engineering and regulatory review. The active phase of decommissioning and reclamation is expected to be completed within approximately three years of the end of operations. Environmental monitoring will continue after reclamation is completed, until such time as the closure objectives as determined in the Closure Plan have been achieved."

It is important to note that this preliminary closure plan, which should include early and unexpected closure but does not, will determine the initial financial security. Thus, all potential major sources of contamination should be identified and costed now, but this is far from the case.

Many serious long-term concerns are omitted and thus cannot be added at this time to the cost of the initial financial assurance. For example, the section on the Underground Mine does not mention the costly and serious water-quality degradation that would likely accompany the backfilling of "PAG" rock into the mine, where the rising, flooding water can become seriously contaminated beyond that seen at the surface. This seriously contaminated flooding water would likely eventually reach an equilibrium level where it would begin flowing out into the surrounding groundwater system and the environment years after closure. This would require long-term or perpetual pumping and treatment of groundwater, which could substantially or enormously raise the financial assurance.

Alternatively, the "PAG" rock (and overburden) could be kept in a stockpile at the surface where its ongoing seepage of infiltrating water through some type of cover would require perpetual collection and treatment. This section implies the ML-ARD would stop by incorrectly saying:

> "Reclamation measures will be designed to mitigate acid mine drainage / metal leaching concerns as needed. This may include design and placement of an appropriate cover over the mineral waste."

ML-ARD is not mitigated cheaply and permeable covers do not stop infiltration but may reduce it if well maintained in perpetuity, still leading to perpetual maintenance and water treatment. Very expensive impermeable covers may virtually encapsulate and isolate the contaminating rock and overburden if carefully maintained in perpetuity, which also includes additional costs for perpetual maintenance and repair.

Or perhaps as Section C.6 on Potential Alternatives states, the mine rock would be used as "reclamation material" where it could contaminate more of the site. Or the mine rock would be placed into "storage in depleted open pit". In the pits, the backfilled mine rock would contaminate inflowing water that would eventually fill and flow into the surrounding environment, or eventually drain down into the underground workings where the second paragraph above explains the fate of the underground water.

One way or the other, the closure cost only for the rock and overburden alone will likely be much higher than envisioned in this perhaps-draft Detailed Project Description.

There are other examples like this that are not recognized and costed in this Section C.3.5.

Therefore, whatever the current estimated cost of financial assurance based on Section C.3.5, it should be raised substantially higher. This would also cover the expense should early or unexpected closure occurs, which is credible and often expected but is not mentioned or considered in this Great Bear document.

10.4 Section F Potential Effects of The Project

Section F on potential effects of the project during Construction, Operations, and Closure starts with Table F.1 Preliminary List of Change to the Environment under Federal Jurisdiction.

The row of Table F.1 for the Fisheries Act during the Construction Phase says:

> "Alteration, disruption and destruction of fish and benthic fauna habitat from direct disturbance (including potentially from overprinting by mine rock and tailings management facilities), blasting and mine dewatering" with the Preliminary Area of Influence only "Project footprint"

For mine dewatering, the ongoing drawdown of groundwater and ongoing dewatering of surface waterbodies does not stop immediately as the pumps are turned off at the end of Operations, but can continue for many years afterwards through Closure. Also, the Area of Influence could be much greater than the Project Footprint (see Section 9.2 of this MDAG review). However, Operations and Closure does not mention this long-term ongoing impact. This illustrates how "Preliminary Changes" are only partially recognized in this Detailed Project Description, and important ones are not mentioned and considered.

Additionally, for Closure under the Fisheries Act Table F.1 says:

> "Potential for creation of fish habitat in new pit lakes, expected to be re-connected to the Dixie Creek system"

This shows a lack of understanding of water-quality impacts and ML-ARD, similar to the Great Bear "nonreactive mine rock and overburden" that does not exist (see Section 10.1 of this review). It sounds good to non-technical readers to say the pit lakes will be fish habitat and "re-connected" to Dixie Creek although they are not currently connected. On the other hand, technical readers know this is highly unlikely considering the type of rock and ML-ARD likely to come from Great Bear rock, pit walls, and underground mine walls. These Great Bear pits as proposed, long after Closure, should not be expected to meet the requirements of the Fisheries Act.

Table F.2 Preliminary Summary of Potential Environmental Effects says:

> "- Underground mine and open pit dewatering will affect the local groundwater levels and may affect surface water flows
> - Groundwater quality is not expected to be affected"
>
> "Preliminary Areal Extent:
> - Dewatering may result in a depression in the local groundwater level which is currently under investigation"

Section 9.2 of this MDAG review explains how Kinross Gold's groundwater modelling is aware of, but avoids showing, the substantial lowering of groundwater levels by dewatering to a remarkable depth of ~600 m in the rock, while the overlying overburden is virtually fully dewatered to its base. This dramatic lowering will be much more than the comfortable sounding word of "local" in the above quotations. It will be much worse than "local". This will also likely have a major impact on groundwater quality, as Section 9 of this MDAG review explains, despite Kinross Gold's unjustified and unreasonable expectation that "Groundwater quality is not expected to be affected".

Furthermore, surface creeks and lakes could be dewatered much more than modelled because modelled groundwater levels are simulated around 9 m higher than measured, reducing the modelled and predicted dewatering below reality. Baseline flows to local surface waterbodies, which are critical to the benthic ecosystem and aquatic life due to their differing chemistry and temperature, will be reduced by 34% and more, but no one yet knows how much more.

Section F.6.1 on Atmospheric Emissions has a major omission that shows the environmental impact from atmospheric emissions would be much greater than stated. Section 8 of this MDAG review has explained that fugitive dust at Great Bear, and any water used to suppress this dust, would have a substantially larger environmental impact than currently recognized and modelled. Thus, impacts from air emissions have been underestimated in this Detailed Project Description that could be used to determine an impact assessment.

Section F.6.2 Liquid Discharges states:

> "Mine water will contain suspended solids from mining and earthmoving activities, ammonia residuals from ammonia-based explosives, and residual hydrocarbons from heavy equipment operation. Leaching of the exposed bedrock within the underground mine and open pit may potentially contribute minor quantities of metals to the mine water."

This is another example of bad science appearing as technical information in this perhaps-draft Detailed Project Description.

- First, underground mine water will also contain dissolved metals and other inorganic contaminants.
- Second, since ammonia is expected to be so high from underground explosives that a special treatment circuit is needed for it, then the always accompanying high nitrate and nitrite that will not be treated but discharged to the environment will also be high and contaminating.
- Third, since underground mine water will contain hydrocarbons, why is there no option to treat these potential organic contaminants?
- Fourth, leaching of mine walls in underground workings and open pits can, and elsewhere have, seriously contaminated the mine water, with the contamination increasing as the area of mine walls increases during mining. This could happen at Great Bear because more than 10 km of underground workings would likely be mined. However, the ML-ARD testwork to predict this under the federal ML-ARD Prediction Manual will be in progress for at least a few years. So, once again this Detailed Project Description misleads by already concluding that the leaching "may potentially contribute minor quantities of metals to the mine water". The reality could just as easily turn out to be "the leaching will contribute substantially high and toxic quantities of metals to the mine water". No one knows yet, not even Kinross Gold and its consultant, WSP.

Some day in a future year, reliable "Modelling will be completed to assess the volume and quality of the water requiring management, which will be used in the design of the integrated water management and treatment facilities on site." At this time, the groundwater requiring management has clearly already been underestimated (see Section 9.2 of this MDAG review). Until then, no one knows with reasonable confidence how much water has to be treated, how severely it will be contaminated, and how thoroughly it will be treated.

The subsection on Process Plant says:

> "Excess process plant water is expected to be pumped with the tailings to a tailings management facility for storage. The tailings and process plant water will contain metals from the processing of metal-containing ore and residual processing reagent products. A cyanide destruction circuit will be established within the process plant to treat residual cyanide concentrations in the tailings and process plant water, prior to pumping to the tailings management facility."

A major aspect of water management and tailings management is the percentage of discharged process water that will be recirculated back to the process to minimize freshwater usage and contamination by "metal from the processing". This issue is not mentioned and thus is a serious omission. Additionally, "cyanide destruction" is not perfect and may not literally destroy cyanide but temporarily mask it until its release to the environment. These important issues are not mentioned either. Thus, this quotation gives the false impression that cyanide and metals will only be "residual" and will be treated to minimize them, but this is simply guessing that is not consistent with ML-ARD testwork so far.

Section F.6.4 on the Environmental Management System does not explain the currently likely scenario that one or more additional contaminants not currently recognized will arise in on-site water (see also Section 11 of this MDAG review). This would require at least months of storage of contaminated water on site until the treatment plant is expanded and updated. Therefore, the on-site storage of months of site-contaminated surface water and groundwater should be a major objective of the Environmental Management System.

10.5 Summary

In summary of this perhaps-draft Detailed Project Description of November 2023, the first cover page by Kinross says this document is "draft", but the second cover page by the authors, WSP, does not say "draft" so perhaps this is the final document. If so, it has not been signed by qualified professionals and thus should be rejected.

In any case, there are so many problems, misleading statements, errors and omission concerning ML-ARD, water quality, and environmental impacts that they cannot all be summarized well here. These problems include the following.

- The false statement that there will be no sources of mercury from the ore processing when in fact the tailings and concentrate from the process will contain mercury. The processing could even cause mercury and other elements to leach more quickly and become more mobile.

- Contrary to the impression given by this Detailed Project Description, cyanide destruction is not perfect and can simply mask the cyanide temporarily in the environment, but the important testwork to determine this has not yet been done for the Great Bear Project.

- Significant impacts on water quality can arise from seemingly benign proposed activities like paste backfill of tailings into the underground mine and dewatered filter-cake tailings, but the potentials for serious impacts are not recognized or not even mentioned in this perhaps-draft Great Bear document.

- Storm events and equipment upsets can lead to relatively large variations and unexpected impacts, day-to-day or even hour-to-hour, during proposed exploration and proposed mining. Instead, these Great Bear documents use averages like monthly which incorrectly assume flows will be the same every day of a month which is far from reality. Environmental impacts and spills can be caused by large variations, as well as longer-term averages, so the environmental risks of proposed exploration and proposed mining at Great Bear remain mostly unknown and not identified.

- Nonsense pseudo-scientific statements are used, like the aggregate required to build the Great Bear Project would be "nonreactive mine rock and overburden" which does not exist. This clearly shows that experienced and qualified professionals were not included in the writing of this perhaps-draft Detailed Project Description. If there is a true commitment to "nonreactive mine rock and overburden" which does not exist, then the Great Bear Project stops now.

- There is a lack of ML-ARD assessments for some site components like aggregate.

- There is a prevalent but likely false belief that "NPAG"rock will have little to no impacts on ML-ARD, water quality, and the environment. However, this has not been proven for the Great Bear Project and is likely wrong based on other minesites around Canada. "NPAG" rock can actually generate more acid than "PAG" rock and still release seriously contaminated levels of many metals and other elements at near-neutral pH.

- The financial assurance to ensure proper and fully paid closure of the proposed Great Bear Project is grossly underestimated based on existing information. Furthermore, the financial assurance should also include contingency costs for early or premature closure but it does not.

- There are likely devastating, expensive, and unrecognized ML-ARD consequences on water quality from the proposed relocation of "PAG" rock into the underground workings after operation.

- The ongoing, unproven, and likely wrong, belief continues that overburden would be environmentally benign, can be used across the site for reclamation, and can be sprayed with water to control dusting when it could instead create contaminating water around, below, and beyond the Great Bear site.

- There are unfounded beliefs that dewatering during exploration and mining would have minimal

effect on the local and regional water balance, and would not significantly dewater surface creeks and lakes including their environmentally important baseflow. These false beliefs are based on flawed groundwater modelling for the Great Bear Project explained earlier in this MDAG review.

- There is a false belief that dust blown off the site during proposed exploration and proposed mining and into the surrounding environment, vegetation, soil, water, and aquatic ecosystems is benign at "background" levels.

- A false belief is stated that only elevated and toxic ammonia, and no other contaminating nitrogen species from explosives that consistently accompany the ammonia, will appear in mine water during proposed exploration and proposed mining.

- There is an unsupported and likely substantially underestimated statement that the mine walls in the pits and underground workings "may potentially contribute minor quantities of metals to the mine water" instead of the more typical significant quantities of metals seen at many other minesites around Canada. This is taken to the likely ludicrous statement that there would be "Potential for creation of fish habitat in new pit lakes, expected to be re-connected [sic] to the Dixie Creek system".

- There is no recognition of the implications, costs, and impacts of storing months of contaminated mine water on the site should one or more "unexpected" yet currently predictable inorganic contaminants and ML-ARD occur on the site water during and after proposed exploration or proposed mining.

11. Water Treatment during Proposed Exploration and Proposed Mining

Most of the contaminated water at the Great Bear Project during proposed exploration and proposed mining would be subjected to water treatment. There would remain some fugitive contaminated water and contaminated dust that would impact the surrounding environment. This fugitive contamination has not been assessed in detail by Kinross Gold, and is even ignored or not recognized in several Great Bear documents as shown above in this MDAG review.

If fugitive contamination turns out to be minimal, then water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts. Therefore, proposed water treatment should be examined and justified in great detail. This has not yet happened for the Great Bear Project.

At this time, I could not find any detailed and professionally certified report on water treatment for proposed exploration and proposed mining. The previous sections of this MDAG review have discussed water treatment as it appeared in some documents, where the current information was found lacking or misleading.

Minewater-treatment plants are not off-the-shelf available at stores like Canadian Tire. This is because their treated effluent concentrations to the environment are very sensitive to the site-specific inflow rate of water and to the inflowing variations in aqueous concentrations of each contaminant element requiring treatment.

These treatment plants can be unstable when exposed to variable flows or to variable inflowing contaminant concentrations, resulting in only partially treated and still-contaminated effluents. Therefore, water treatment for proposed exploration and then again for proposed mining at the Great Bear Project has to be carefully designed, based on well-justified and professionally certified information on surface hydrology, subsurface hydrogeology, ML-ARD, and on-site geochemical source terms.

As shown in the previous sections of this MDAG review, this "input" information into the site-specific and reliable design of water treatment at Great Bear does not exist and will not likely exist for at least a few years. Until then, the available preliminary information is corrupted by errors and missing details. Therefore, it is not possible at this time to reliably define and design the required water treatment at Great Bear, or to estimate effluent concentrations, environmental impacts, and cumulative effects.

To provide some guidance to Grassy Narrows First Nation on aspects of water treatment at the Great Bear Project, it is helpful to review and comment on one of the latest documents that contain some details on possible water treatment. This document is: Great Bear Project Proposed Underground and Open Pit Gold Mine, a PowerPoint presentation made to Asubpeeschoseewagong Netum Anishinabek, dated November 10, 2023

Slide 20 of this presentation is entitled "Water Treatment". It points out that:

> "Contact water discharged to the Chukuni River will be managed to achieve regulatory requirements."

It is important for Grassy Narrows First Nation to recognize that "regulatory requirements" can vary vastly and that the applicable and protective requirements have to be carefully chosen based on site-specific information like flow rates and variations in influent (ML-ARD) and effluent concentrations. Alarmingly, Table 5-6 shown on Slide 20 invokes the "MDMER" or Metal and Diamond Mine Effluent Regulations, which allow toxic levels of metals and other elements. For example, normally toxic levels of 100 ug/L and more are allowed for arsenic and copper, and normally toxic 80 ug/L and more are allowed for lead.

This should be an immediate warning to Grassy Narrows First Nation that Kinross Gold does not intend to treat the site water to safe levels. Instead, treatment will only reduce concentrations to still-toxic levels and then rely on dilution in the Chukuni River to eventually reduce it almost to background levels.

The usage of toxicity dilution in the Chukuni River would create a "mixing zone" for some distance in the river, in which toxicity still exists and for which Fisheries and Oceans Canada would have to authorize the mixing zone. There appears to be some hydrodynamic modelling already done for this mixing zone in the River, but no details like flow rates and their variabilities were provided. Because the previous sections of this MDAG review showed that long-term to perpetual treatment and dilution may be needed for the Great Bear Project, Grassy Narrows First Nation should understand this will represent a very-long-term impact.

Additionally, such long-term ongoing discharge and dilution will add to cumulative effects, about which Grassy Narrows First Nation has expressed serious concerns.

Slides 20 and 21 present additional details on treatment. For example, a special and likely expensive ammonia treatment circuit will be included to treat elevated and toxic ammonia from blasting residues. Remarkably, nitrate and nitrite, which can also be toxic and can stimulate eutrophication in the Chukuni River and Dixie Creek, always accompany ammonia from the blasting residues. However, they are not even recognized here or in other Great Bear documents. This is a serious and unacceptable omission for the Great Bear Project.

Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

Slide 20 also commits to "ultrafiltration" which typically removes all suspended particles coarser than about 0.02 um. Because "dissolved" concentrations include nanoparticles and small particles up to about 0.45 um, this proposed ultrafiltration would also lower the functionally "dissolved" concentrations, but not those of fully dissolved elements. Thus, Great Bear treatment should be capable of approaching CCME (Canadian Council of Ministers of the Environment) safe criteria for aquatic life, but may not meet Grassy Narrows First Nation water-quality criteria (GNFNWQC). CCME aquatic-life guidelines and GNFNWQC could replace the toxic MDMER criteria and significantly reduce or eliminate the mixing zone and cumulative effects in the Chukuni River.

However, none of these details are discussed or mentioned in Great Bear documents.

Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge". In many jurisdictions, treatment sludge like that proposed for the Great Bear Project can reach "hazardous" or "special" waste levels, requiring the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and in sediments including soils and benthic ecosystems.

All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge. This is a major risk for serious environmental impacts that should be addressed in great detail for proposed exploration and proposed mining. I recommend that Grassy Narrows First Nation require intensive studies on the treatment sludge that will remain and be managed somewhere in perpetuity.

In summary for water treatment, Great Bear documents invoke water treatment as the major process that would prevent or minimize environmental impacts of proposed exploration and proposed mining. This is not literally true, because there will be fugitive contaminated water and contaminated dust leaving the site, but this fugitive contamination is ignored or not recognized in many reviewed Great Bear documents.

In any case, water treatment is the last "line of defence" between the on-site ML-ARD and contamination and the off-site impacts, and thus requires intensive study and characterization. However, at this time, water treatment for proposed exploration and proposed mining is ambiguous and contradictory among the documents. This should be expected because the input flows and input contaminant concentrations (ML-ARD) will not be known reliably for at least a few years. Nevertheless, there are serious concerns about water treatment now including the following.

- Kinross Gold does not expect to treat site water to non-toxic levels. Instead, treatment would only be down to still-toxic levels based on the Metal and Diamond Mine Effluent Regulations. Thus, Kinross Gold intends to rely on significant dilution of its contaminated effluent within a "mixing zone" in the Chukuni River. Such a mixing zone would include zones of significant toxicity and would require formal authorization from Fisheries and Oceans Canada. In any case, this discharge of effluent would add to cumulative effects, which is a particular concern of Grassy Narrows First Nation.

- Expensive and intensive treatment for ammonia, derived from blasting residues, is proposed. However, toxic levels of nitrate and nitrite, that always accompany the ammonia and which can cause eutrophication and other impacts in the Chukuni River and Dixie Creek, are completely ignored.

- Sulphate concentrations in the treated effluent, which I understand can increase toxic methylation of mercury and other elements like cadmium and arsenic, are not mentioned at all.

- Ultrafiltration may substantially reduce effluent concentrations for those elements not fully

dissolved, mixing-zone size, and cumulative effects. However, there are no details on this ultrafiltration in the reviewed Great Bear documents.

- Mine water treatment plants remove metals and other elements from the water, by creating concentrated and toxic treatment waste commonly called "sludge", which can reach "hazardous" and "special" waste levels in some jurisdictions. Thus, treatment sludge requires the most careful and secure handling and long-term storage under contaminated-sites regulations. Spills of this sludge can result in toxic conditions in water and sediments including soils and benthic ecosystems. All the Great Bear documents I have reviewed so far are completely silent on the annual volumes, handling, storage, long-term protection, and potential environmental impacts of treatment sludge that will remain and be managed somewhere in perpetuity.

Re: Great Bear Resources Ltd. ("Great Bear") – Great Bear Gold Project ("Project") – Response to Asubpeeschoseewagong Netum Anishinabek ("ANA") Request for Review Panel

We are writing in response to the letter dated 17 June 2024 ("**Request Letter**") from ANA to the Impact Assessment Agency ("**IAAC**") requesting a review panel pursuant to section 36 of the *Impact Assessment Act* ("**Act**") to review the Project.

For the reasons set out in this letter, Great Bear submits that a review panel is not necessary for the assessment of the Project under the Act. A thorough, comprehensive impact assessment ("**IA**") can be undertaken through the IAAC-led process. The IAAC-led process is also adaptable to respond in detail to specific issues that may arise related to Indigenous community interests.

1. Section 36(2) establishes the Minister's decision criteria

The Minister's authority to refer an impact assessment to a review panel is set out in section 36(2) of the Act, which reads as follows:

> 36(2). The Minister's determination regarding whether the referral of the impact assessment of the designated project to a review panel is in the public interest must include a consideration of the following factors:
>
> (a) the extent to which the effects within federal jurisdiction or the direct or incidental effects that the carrying out of the designated project may cause are adverse;
>
> (b) public concerns related to those effects;
>
> (c) opportunities for cooperation with any jurisdiction that has powers, duties or functions in relation to an assessment of the environmental effects of the designated project or any part of it; and

(d) any adverse impact that the designated project may have on the rights of the Indigenous peoples of Canada recognized and affirmed by section 35 of the Constitution Act, 1982.

The circumstances of this Project assessment do not warrant a panel review based on a reasonable consideration of any of the relevant criteria in section 36(2). The ANA request focusses on potential impacts that fall under section 36(2)(d), which we respond to in section 4.

2. Mining activity in the Red Lake area is common, and the effects are well-understood.

The Project is in the Red Lake District in Ontario, a prolific mining district with an almost 100-year mining history. Given the large number of mining projects that have operated in this area, the geological, environmental, and social characteristics of the area are well-studied and understood. The local communities derive many benefits from the mining in the area, including employment and contracting to support those communities, and support mining.

Mining activities in the Red Lake District are subject to stringent environmental regulations and oversight by federal and provincial authorities. Accordingly, mining operations adhere to applicable environmental standards and manage any risks to local ecosystems and communities to appropriate standards.

Indigenous communities in the area have experience engaging with mining proponents and have negotiated various agreements and economic collaborations, resulting in community investments, employment opportunities, sustainable development, local land stewardship protocols, and an increase in positive, equitable relationships.

The existing record within the relevant provincial and federal regulatory agencies establishes a solid foundation to provide additional context for the Project-specific information that Great Bear will file for this IA.

3. Local Indigenous communities support mining if their interests are met

Great Bear has engaged with local Indigenous communities throughout the federal environmental assessment process thus far. Because of Great Bear's meaningful consultation and engagement, Lac Seul First Nation ("**Lac Seul**") and Wabauskang First Nation ("**WFN**") have indicated that they are open to the Project if the Project meets their interests.

Lac Seul and WFN have supported the Advanced Exploration program preceding the Project, and are engaged in negotiations with Great Bear for an agreement on the mine phase of the Project which would establish the basis upon with the Project would proceed with their support.

The Minister and IAAC must assess and reconcile the interests of Great Bear and all the local communities that will be affected by the AEX Permit and the Project. [1]

[1] See the *Ermineskin Cree Nation v. Canada (Environment and Climate Change)*, 2021 FC 758 (CanLII) case, in which the Federal Court decided that the Crown must consult with and consider the impact on the economic rights and benefits of Indigenous communities who have economic accommodation agreements.

4. The location, nature, and scale of the Project do not create the potential for adverse impacts that warrant the appointment of a Review Panel

In its letter to the IAAC, ANA cited various mine projects that had been referred to an independent review panel. Each of these projects had unique circumstances and potential impacts that are not analogous to the Great Bear Project. Specifically, those projects had circumstances that added to the complexity of their assessment, including the following: unique environmental conditions; a larger scale and scope of the construction or operation; a larger operational footprint or facilities; or local opposition.

It is more relevant to consider the Project on its own merits and against projects in the same region or Ontario. As noted in section 3 above, the region is a prolific mining region with many mine projects. Compared to other projects in the region, the Great Bear Project has less potential for adverse effects for the following reasons:

- The geographic footprint is relatively small.
- The construction and operation will involve well-understood practices that do not involve any complications or novel features.
- The potential environmental effects are limited in nature and scale and can be minimized by reasonable mitigation measures.
- The mining and processing will occur on the same site.
- The logistics to support the operation will be limited in nature and scale.
- The construction and operation will employ leading industry practice.

Other Ontario projects that have been larger in nature, scale and complexity have been assessed without the need for an independent review panel, including the following examples:

- The Greenstone Gold Project near Geraldton involved moving a highway, diverting a fish-bearing stream, a brownfield site with contaminated arsenic issues, a much larger processing plant, and required the relocation of historical tailings into the newly constructed tailings facility.
- The Côté Gold Project near Sudbury involved moving and draining streams and lakes, and a has much larger processing plant than what is planned for the Great Bear Project.
- The Magino Gold Project near Wawa involved moving and draining streams and a lake.
- The Detour Gold Project near Cochrane involved moving and draining streams and lakes, and a much larger processing plant.

The projects cited by ANA in other regions also involved elements that differ from the Great Bear Project. For example:

- The Marathon Platinum Group Metals and Copper Mine Project was an open-pit mine for platinum group metals and copper in Ontario. It involved substantial surface disturbance and

potential effects on the environment, including effects on wetlands and water bodies, water quality, aquatic ecosystems, and wildlife habitats. Indigenous communities raised issues regarding the adequacy and meaningfulness of consultation processes, as well as voiced concerns about the potential impacts of mining activities on culturally significant sites, archaeological resources and sacred areas within the project area.

- Suncor Base Mine Extension Project (Alberta)
- Rose Lithium – Tantalum Mine Project and the James Bay Lithium Mine Project (Quebec)
- The Grassy Mountain Coal Project in Alberta was large-scale open-pit coal mine that involved substantial changes to the landscape and local ecosystems and raised concerns about potential impacts on water quality, wildlife habitat, and Indigenous rights.
- Robb Trend Coal Mine Expansion Project (Alberta)
- Frontier Oil Sands Mine Project (Alberta)
- Jackpine Mine Expansion Project (Alberta)
- Pierre River Mine Project (Alberta)
- The Prosperity Gold-Copper and New Prosperity Gold-Copper Mine Projects in British Columbia was an open-pit gold-copper mine located in the Fish Creek Watershed, a part of the Fraser River watershed. The area is ecologically sensitive and supports critical spawning and rearing habitats for salmon species, and the project's development would have involved significant disturbances to the local environment, including the potential for acid mine drainage and impacts on water quality. Local communities, environmental organization, and Indigenous communities raised concerns about the potential for long-term environmental damage, risks to local water resources, impacts on recreational and tourism activities, and overall sustainability of the proposed development in the area.

5. The IAAC-led IA is comprehensive and sufficient

The IAAC-led IA is comprehensive and adaptable to meet the needs of the participants. It is more than sufficient to assess any potential environmental, social, health, cultural, or economic impacts of the Project. IAAC can call on expertise from the other federal agencies as needed and work collaboratively with the provincial agencies with expertise.

IAAC has expertise and experience to consult with and respond to all reasonable concerns raised by Indigenous and local communities.

6. Concluding comments

Great Bear seeks to establish a positive, collaborative relationship with the local Indigenous communities and will respond to all reasonable interests. Great Bear believes it can undertake all phases of the Project in a manner that respects those interests through good practice in the design and implementation of the Project, incorporating input from the Indigenous communities.

Great Bear follows industry best practices, adhering to all relevant and applicable federal, provincial, and local regulations governing mining activities. A key tenet of Great Bear's operations is its commitment to meeting or exceeding environmental standards through their environmental management plans, mitigation measures and monitoring protocols.

Great Bear would be pleased to elaborate on any of the points in this letter.

We look forward to your response.

Re: Great Bear Resources Ltd. ("Great Bear") – Great Bear Gold Project ("Project") – Response to Asubpeeschoseewagong Netum Anishinabek ("ANA") Request for Review Panel – Supplemental Comment

For the reasons set out in Great Bear letter dated 9 July 2024, Great Bear maintains that a Review Panel is not required for this Project.

We understand that Lac Seul First Nation ("**LSFN**") and Wabauskang First Nation ("**WFN**") have filed or will file a submission in which they also explain that they also do not see a Panel review as necessary.

LSFN and WFN explain that they have designed an Anishinaabe-led Assessment ("**ALA**") process to complement an Agency-led review of the Great Bear Project, rather than a Panel review. Great Bear has agreed to assist LSFN and WFN on this ALA and will respect the outcome of that review.

Great Bear would be pleased to elaborate on any of the points in this letter.

Regards,

NEWS RELEASE

Kinross completes Great Bear Preliminary Economic Assessment

Annual production over 500,000 ounces[1]
Impressive margins with low AISC[2] of ~$800/oz
Drilling beyond PEA inventory shows high-grade mineralization at depth

Toronto, Ontario – September 10, 2024 – Kinross Gold Corporation (TSX: K, NYSE: KGC) ("Kinross" or the "Company") today is pleased to provide an update on the Great Bear project (the "Project"), located in Red Lake, Ontario, Canada.

This news release contains forward-looking information about expected future events and financial and operating performance of the Company. We refer to the risks and assumptions set out in our Cautionary Statement on Forward-Looking Information located on page 13 of this release. All dollar amounts are expressed in U.S. dollars, unless otherwise noted.

Kinross has completed a Preliminary Economic Assessment (PEA) for the Great Bear project which supports the Company's acquisition thesis of a top tier high-margin operation in a stable jurisdiction with strong infrastructure. Based on mineral resources drilled to date, the PEA outlines a high-grade combined open pit and underground mine with an initial planned mine life of approximately 12 years and production cost of sales[3] of $594 per ounce. The Project is expected to produce over 500,000 ounces per year at an all-in sustaining cost (AISC)[2] of approximately $800 per ounce during the first 8 years through a conventional, modest capital 10,000 tonne per day (tpd) mill.

Kinross has also released an updated mineral resource estimate increasing the inferred resource estimate by 568koz. to 3.884 Moz. which is in addition to the existing M&I resource estimate of 2.738 Moz[4]. The mineral resource estimate and PEA for the Great Bear project are available here.

CEO Commentary:

"This PEA marks an important milestone for Great Bear and reaffirms our view of it as a high-quality asset with robust economics and a clear path to become a world class operating mine," said Paul Rollinson, Chief Executive Officer of Kinross Gold Corporation. "The Project represents a strong combination of high-margin production and modest capital requirements, with the opportunity for significant resource growth in the future.

"This PEA represents the first view of unlocking Great Bear's full potential. Based on surface drilling to date, the PEA provides an initial snapshot in time of the Project. The ongoing drilling to depth has already shown multiple wide, high-grade intercepts beyond the current resource used in the PEA. This deep drilling from surface demonstrates the continuation of mineralization at depth and the upside potential for further resource and mine life additions in the future as we progress exploration from depth.

"These positive results are underpinned by a strong mining jurisdiction with a skilled labour pool and solid regional infrastructure. We have both the financial and technical resources to advance the development of this exciting new Project in our portfolio."

[1] *Annual production over 500,000 ounces for the first 8 years.*
[2] *AISC is a non-GAAP financial measure. The definition and purpose of this non-GAAP financial measure is included on page 11 of this news release. Non-GAAP financial measures and ratios have no standardized meaning under IFRS and therefore, may not be comparable to similar measures presented by other issuers. Please see average production cost of sales in the table entitled "PEA study financial highlights" for the related estimated GAAP financial measure.*
[3] *"Production cost of sales per ounce" is defined as production cost of sales divided by total ounces sold. In the PEA, production costs of sales is referred to as production cash costs.*
[4] *See the table below titled "Great Bear Summary of project mineral resources" for grade and quantity of mineral resource estimate.*

Kinross Gold Corporation
25 York Street, 17th Floor
Toronto, ON Canada M5J 2V5

Key PEA Highlights:

- The Great Bear PEA demonstrates a top-tier high margin operation in a stable jurisdiction in Ontario, Canada. The Project is located within the prolific Red Lake Greenstone Belt 24 kilometres from Red Lake, a town with a long history of mining, significant infrastructure including a paved highway and provincial power lines, and access to experienced, skilled labour.
- The results from the PEA affirm that Great Bear has the potential to be a cornerstone asset with a top tier production profile, low costs, and significant value.
- The PEA mine plan demonstrates an excellent estimated internal rate of return (IRR) and after-tax net present value (NPV) at a range of gold prices.

PEA study physical highlights[5]	
Annual production (koz. / first 8 years)	518
Annual production (koz. / life of mine average)	431
Life of mine production (Moz. Au)	5.3
Mill Processing rate (tpd)	10,000
Underground peak mining rate (tpd)	6,000
Life of mine tonnes processed (million tonnes)	44.6
Average grade processed (g/t Au)	3.87
Average recovery rate (% Au)	95.7

PEA study financial highlights	
Average production cost of sales (per Au oz.)[3,6]	$594
Average all-in sustaining costs (per Au oz.)[2,6]	$812
Total initial construction capital cost (US$ millions)	$1,181
Total capitalized mine development (US$ millions)	$248
Total initial project capital (US$ millions)	$1,429

Great Bear IRR and NPV estimates based on gold price[7,8,9,10]	$1,900/oz.	$2,500/oz.
IRR	24.3%	35.5%
NPV	$1.9 billion	$3.3 billion
Payback period (years)	2.7	1.7

[5] The PEA is preliminary in nature and is based, in part, on Inferred Mineral Resources. Inferred Mineral Resources are considered too geologically speculative to have the economic considerations applied to them that would enable them to be categorized as Mineral Reserves. There is no certainty that the economic forecasts on which the PEA is based will be realized.
[6] Average production cost of sales and average AISC represent costs for projected production for the life of mine.
[7] The economic analysis of the project was carried out using a discounted cash flow approach on a pre-tax and after-tax basis, based on a long-term gold price of $1,900/oz in USD and cost estimates prepared in CAD.
[8] An exchange rate of 0.74 USD per 1.00 CAD was assumed to convert CAD market price projections and particular components of the capital cost estimates into USD.
[9] The IRR on total investment that is presented in the economic analysis was calculated assuming 100% equity financing except open pit fleet, though Kinross may decide in the future to finance part of the project with debt financing.
[10] The NPV was calculated from the after-tax cash flow generated by the project, based on a discount rate of 5% and a valuation date of January 1, 2026.

Toronto, ON Canada M5J 2V5

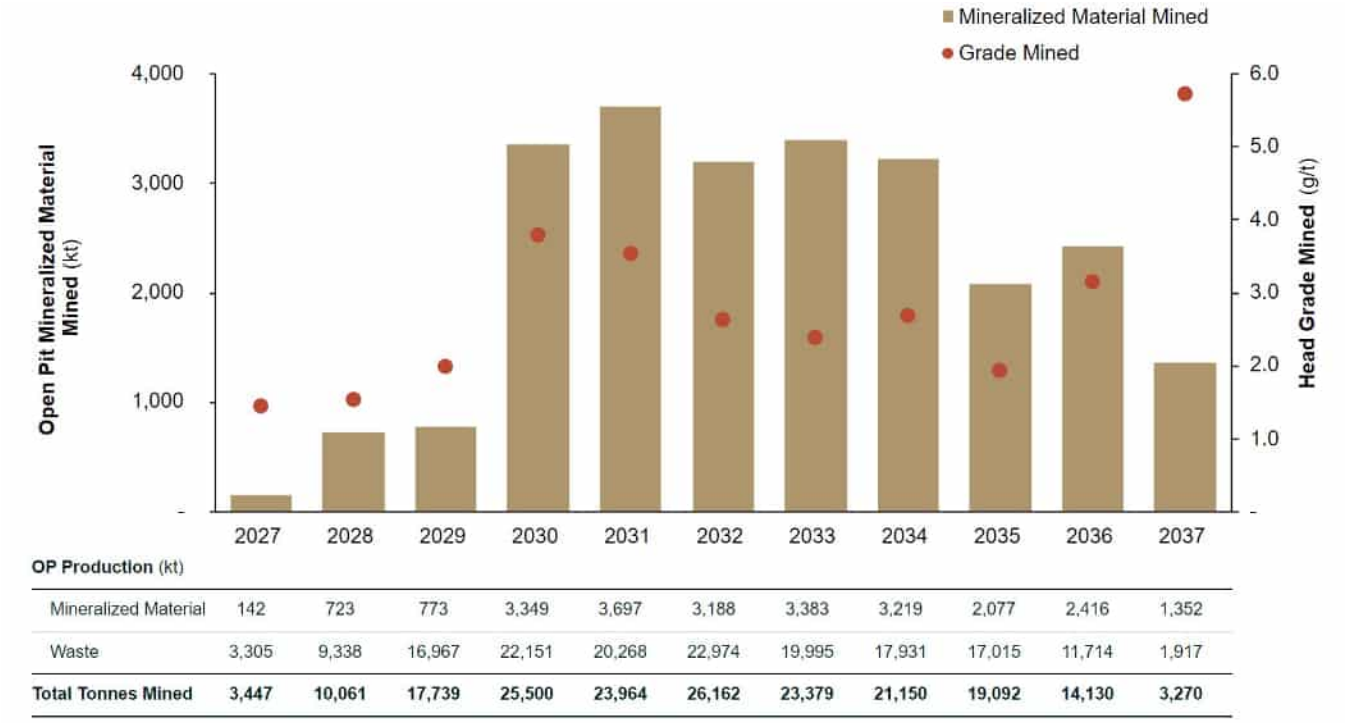
Mine Plan

The initial mine plan outlines concurrent open pit and underground mining over the first 8 years followed by combined underground mining and stockpile processing in years 8 to 12. The decision to mine the open pit and underground concurrently from the start provides significant production flexibility and time to continue exploration drilling from underground to further expand the resource and mine life.

The PEA demonstrates an initial life-of-mine (LOM) of approximately 12 years with total production of approximately 5.3 Moz. of gold. However this represents a point in time estimate of the mine plan and is only a window into the long-term potential of the asset given the limitations of drilling at depth from surface. Exploration drilling at depths up to 1,600 metres has already demonstrated continuation of high-grade mineralization with strong widths well below the current PEA inventory, highlighting the upside potential of this asset.

The high-grade open pit will be mined with a dual fleet strategy to provide selective mining of the high-grade material and lower cost mining of the waste, mining a peak of 26 million tonnes of material, and providing a peak of 9,000 tpd of mineralized material.

Figure 1: Open Pit mining plan



OP Production (kt)	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037
Mineralized Material	142	723	773	3,349	3,697	3,188	3,383	3,219	2,077	2,416	1,352
Waste	3,305	9,338	16,967	22,151	20,268	22,974	19,995	17,931	17,015	11,714	1,917
Total Tonnes Mined	**3,447**	**10,061**	**17,739**	**25,500**	**23,964**	**26,162**	**23,379**	**21,150**	**19,092**	**14,130**	**3,270**

For the underground, the primary mining method is long hole open stoping with paste backfill and cemented rock fill. First stope production is expected to begin in 2029, subject to permitting, and to continue for 12 years with a peak production rate of 6,000 tpd, with potential to expand beyond this run rate as extensions to the underground resource are targeted. At peak, the underground will have a mining rate of 6,000 tpd between 2035 and 2038, producing an average of 327koz. per annum.

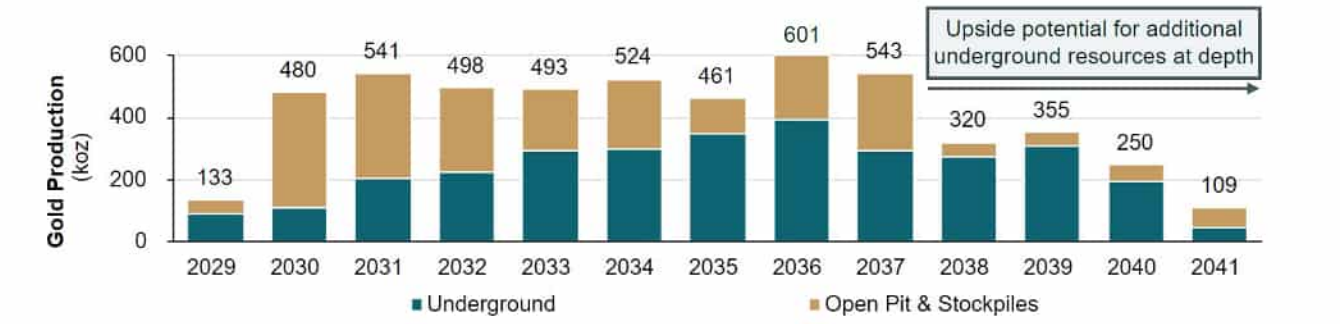
Kinross Gold Corporation
25 York Street, 17th Floor
Toronto, ON Canada M5J 2V5

Figure 2: Underground mining plan

	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038	2039	2040	2041
U/G Production *(ktpd)*	1.5	2.3	3.5	3.9	5.1	5.1	6.0	6.0	6.0	6.0	5.2	3.5	1.1
U/G Milled Grade *(g/t)*	4.7	4.4	5.2	5.1	5.1	5.2	5.2	5.7	4.3	4.1	5.2	4.9	3.7
O/P & SP Milled Grade *(g/t)*	3.0	4.6	4.6	4.0	3.7	4.1	2.5	4.7	5.5	1.1	0.9	0.8	0.7
Avg. Milled Grade *(g/t)*	**4.0**	**4.6**	**4.8**	**4.4**	**4.4**	**4.6**	**4.1**	**5.3**	**4.8**	**2.9**	**3.2**	**2.2**	**1.0**

The combination of the open pit and underground production in the years 1 to 8 will allow for processing of higher-grade material and stockpiling of the remaining feed to supplement underground production in the latter years of the mine life. This strategy drives a milled grade of 4.6 g/t in years 1 to 8 and an average production of 518koz. per annum over these years.

Figure 3: Concurrent Open Pit and Underground Gold Production



Kinross Gold Corporation

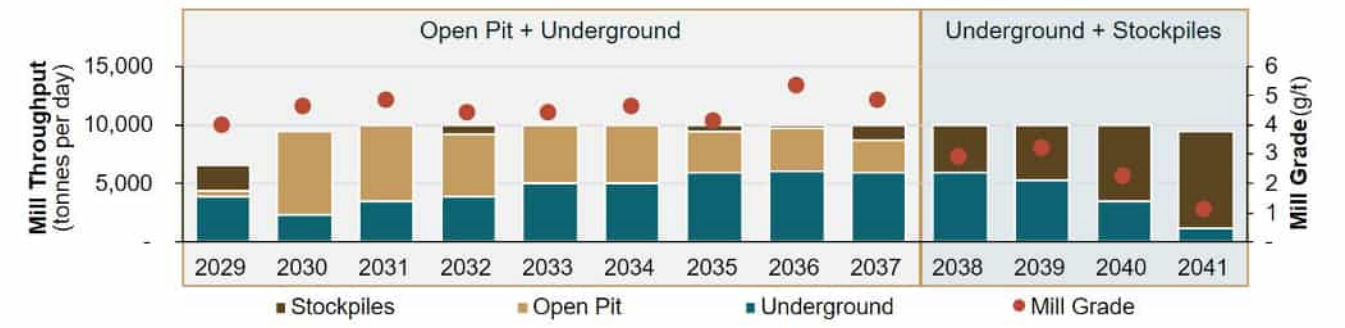
Toronto, ON Canada M5J 2V5

Figure 4: Mill Throughput



Open pit mining operations	
LOM material mined	187.9 Mt
LOM plant feed mined	24.3 Mt
Average grade	3.0 g/t Au
Strip ratio	6.7 (waste: plant feed)
Peak mining rate (all materials)	26.2 Mtpa
Mining unit cost (including capitalized mining)	$3.59 ($/t mined)
Underground mining operations	
LOM plant feed mined	20.3 Mt
Average grade	4.9 g/t Au
Steady State Mining Rate (plant feed)	6,000 tpd
Mining unit cost (excluding capitalized mining)	$68.70 ($/t processed)

Mill, Processing and Tailings Design

For the PEA, a conventional milling circuit for free milling mineralization was selected, targeting an average processing rate of 10,000 tpd. This scale of plant configuration simplifies construction, drives high margins and production scale in the early years with selective processing of higher-grade material when mining both open pit and underground, and avoids oversizing the mill for a potential underground only scenario in the latter years of the mine life at Great Bear.

Kinross has completed a comprehensive metallurgical test work program including detailed chemical head analysis, mineralogy, gold deportment, comminution, and leaching and gravity recovery testing across a selection of composite samples. The results of the test work program indicated clean metallurgy with no deleterious elements and very strong recoveries, with average LOM recovery of 95.7% projected in the PEA. The clean metallurgy and conventional circuit are expected to further de-risk project construction and execution.

Based on the metallurgical test results, Great Bear's processing plant has been designed as a conventional circuit with a proposed flowsheet including semi-autogenous grinding (SAG) and ball milling, pebble crushing, gravity concentration, leaching followed by carbon-in-pulp adsorption (CIP), elution, electrowinning, and smelting to produce gold doré.

Kinross Gold Corporation
25 York Street, 17th Floor
Toronto, ON Canada M5J 2V5

Key Processing Data	
Mill processing rate (tpd)	10,000
Total plant feed (Mt)	44.6
LOM avg. feed grade (g/t Au)	3.87
LOM contained gold (Moz)	5.5
LOM avg. recovery (% Au)	95.7
LOM recovered gold (Moz)	5.3

Kinross has invested substantial effort into early technical studies and design for tailings processing and management facilities at Great Bear leveraging the best available technologies to ensure the highest environmental standards.

As a result, the PEA design includes the addition of a desulphurization flotation circuit to remove sulphides and render the tailings non-acid generating, and a rigorous design criteria for all tailings storage facilities at the site.

As well, the LP Viggo Pit has been pulled forward to be mined during project construction in order to provide a robust in-pit tailings storage facility for the sulphide concentrate from the desulphurization flotation circuit, eliminating the need for a dam to impound the sulphide concentrate.

Capital Expenditure

The total initial construction capital is forecasted at $1.2 billion. Capitalized mine development prior to commercial production is expected to be approximately $250 million, comprised of $105 million related to open pit mining and $143 million related to underground capital development which will support higher production in the early years. The majority of the capitalized open pit mining is driven by the strategic decision to pull forward mining of the Viggo pit during construction to provide low-cost construction rock, early mill feed and a robust in-pit solution for the tailings concentrate.

Within the construction capital, the site development, water treatment and infrastructure area includes the truck shop, admin facilities, and camp. It also includes state of the art water treatment including ultra-filtration and a robust site-wide water management strategy to ensure the highest environmental standards.

Additionally, the capital estimate includes indirect and contingency costs, where indirect and owner costs are 40% of total direct costs and the contingency is 22%, providing further confidence in the PEA's total estimate.

The Project's capital requirements are expected to be manageable for Kinross and are forecasted within the Company's planned annual capex profile in the range of $1 billion. Kinross is confident it can continue to prioritize its investment grade balance sheet and comfortably fund Great Bear, along with other planned capital spending.

25 York Street, 17th Floor
Toronto, ON Canada M5J 2V5

Great Bear capital cost estimates *(US$ millions)*		
Direct Capital Costs		
	Mine equipment	$85
	Site development, water treatment and infrastructure	$239
	UG Infrastructure	$49
	Processing	$217
	Power	$47
	Tailings management facility	$52
	Total Direct Costs	**$689**
	Indirect	$276
	Contingency	$216
Total Initial Construction Capital Cost		**$1,181**
	Capitalized open pit mining	$105
	Capitalized underground development	$143
Total Capitalized Mine Development		**$248**
Total Initial Project Capital		**$1,429**
Life of Mine Sustaining Capital		**$1,034**
Total Growth Capital		**$97**[11]

Next Steps and Permitting

Kinross is continuing to progress work in several areas across the Project, for both the advanced exploration program (AEX) and the Main Project. Both the AEX and Main Project remain subject to permitting, which continues to advance. The AEX permitting is a provincial process and Kinross is working closely with the authorities on finalizing the permits. The Main Project's permitting is mainly a federal permitting review process driven by the Impact Assessment Agency of Canada (IAAC), with some provincial permitting components. Kinross was pleased to recently receive the Tailored Impact Statement Guidelines from IAAC, which will assist with completing the draft Impact Statement.

For the AEX, detailed engineering, execution planning, and procurement continues to progress well. The Company is targeting to commence surface works in 2024, subject to receiving provincial permits.

For the Main Project, Kinross expects to advance engineering definition and execution planning following the selection of design partners later this year. Work on permitting of the Main Project is ongoing and will require federal review under the Impact Assessment Act. An Impact Statement is currently in process and is expected to be submitted to the IAAC next year.

Kinross has actively engaged and consulted with Indigenous communities and organizations and has commenced negotiations of a Project Agreement with its First Nations partners, Lac Seul and Wabauskang, on whose traditional territories the Great Bear project is located.

11 The long-term power supply strategy for the Project is to obtain enough power supply from the Ontario power grid to avoid self-generation and the use of natural gas. To secure the necessary grid power supply, Kinross estimates it will need to make a capital contribution of approximately $97 million.

Kinross Gold Corporation
25 York Street, 17th Floor
Toronto, ON Canada M5J 2V5

Resource update and exploration

The Mineral Resources[12] at the property have been estimated for three zones: LP, Hinge, and Limb. As of April 2, 2024, approximately 568,000 ounces of inferred resources have been added from the LP zone to the total resource compared to year end 2023, bringing the total inferred resource to 3.9 Moz., in addition to 2.7 Moz. of M&I resources.

Mineral resources have been calculated at a gold price of $1,700 and the open pit reflects a $1,400 pit shell. The open pit cutoff grade is 0.55 g/t and the underground cut off grade of is 2.3 g/t for the main LP zone. The $1,400 pit shell has been chosen as this represents the optimal trade-off point at which underground extraction below the pit shows higher potential margins then deepening the open pit.

Great Bear Summary of project mineral resources[13,14,15,16,17,18]
(as at April 2, 2024)

Classification	Tonnes (000)	Grade (g/t Au)	Gold Ounces (000)
Measured	1,556	3.04	152
Indicated	28,711	2.80	2,586
TOTAL M&I	**30,267**	**2.81**	**2,738**
Inferred	**25,480**	**4.74**	**3,884**

Given the Company's current understanding of the orogenic system, and the significant high-grade extensions realized at the main LP zone, Kinross expects the strong grades to continue as drilling extends deeper. To date, Kinross has completed more than 420 kilometres of drilling on the property and results have been very strong, supporting the Company's view that high-grade mineralization extends at depth and indicating the potential for resource growth over time.

Kinross' 2023 and 2024 exploration program resulted in the addition of significant ounces at improved grades compared with the initial project mineral resource declared at year end 2022, with the bulk of additions in the high-grade underground between 500 metres and 1 kilometre.

This recent drilling, highlighted by the deepest hole drilled on the property to date, which returned 3.8 metres at a grade of 9.5 g/t at nearly 1.6 kilometres vertical depth at the LP zone, demonstrates the impressive continuity of this system. Exploration drilling at Great Bear continues to see success beyond the PEA inventory. Drill holes BR-888 and BR-888C2 are the deepest drill holes on the property to date and have intersected high grade mineralization 1,600 metre vertically below surface.

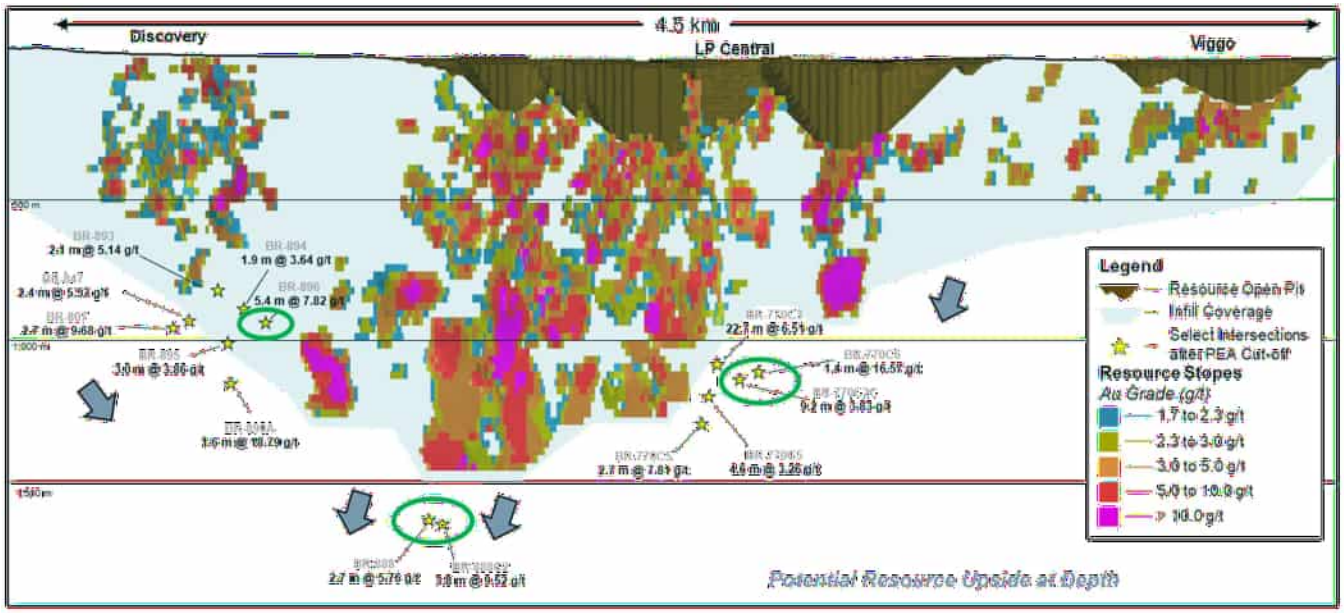
Furthermore, exploration drilling at both the Discovery and Yauro zones have also intersected mineralization beyond the PEA inventory. Drill hole BR-770C3 intersected 22.7 metres at 6.51 g/t at Yauro and BR-896 intersected 5.4 metres at 7.82 g/t at Discovery. These drill holes demonstrate the successful expansion of mineralization through drilling, not just at depth, but along strike and linking zones.

---

[12] Mineral Resources are stated in accordance with CIM (2014) Definitions as incorporated by reference into NI 43-101. Mineral Resources are estimated for the LP zone and satellite Hinge and Limb zones and have an effective date of April 2, 2024.
[13] Mineral resources estimated according to CIM (2014) Definitions.
[14] Mineral resources estimated at a gold price of $1,700 per ounce.
[15] Open pit mineral resources are reported within optimized pit shells at a cut-off grade of 0.55 g/t Au.
[16] Underground mineral resources are reported within underground reporting shapes at cut-off grades of 2.3 g/t Au for the LP zone, 2.5 g/t Au for the Limb zone, and 2.4 g/t for the Hinge zone. An incremental cut-off grade of 1.7 g/t Au was used at the LP zone for areas that do not require additional development.
[17] Mineral resources that are not mineral reserves do not have demonstrated economic viability.
[18] Numbers may not add due to rounding.

Kinross Gold Corporation
25 York Street, 17th Floor
Toronto, ON Canada M5J 2V5

Figure 5: Resource Growth - continuing to see high-grade intercepts outside of the PEA inventory



The PEA represents a point in time estimate and is only a window into the long-term potential of the asset given the indications of continued mineralization at depth. As a result, the Company is focused on progressing the AEX to begin drilling underground to continue unlocking the full potential of the asset.

In 2024, the Company will continue to focus drilling to link zones at depth at LP and further directional work at Hinge and Limb. Exploration will also focus resources on brownfield exploration work on the newly expanded ~120 square kilometre land package to look for additional open pit and underground opportunities.

Great Bear Technical Presentation details

In connection with this news release, Kinross will hold a conference call and audio webcast on Tuesday, September 10, 2024, at 9:00 a.m. EDT, followed by a question-and-answer session. To access the call, please dial:

About Kinross Gold Corporation

Kinross is a Canadian-based global senior gold mining company with operations and projects in the United States, Brazil, Mauritania, Chile and Canada. Our focus is on delivering value based on the core principles of responsible mining, operational excellence, disciplined growth, and balance sheet strength. Kinross maintains listings on the Toronto Stock Exchange (symbol: K) and the New York Stock Exchange (symbol: KGC).

APPENDIX A

Non-GAAP financial measures

The Company has included certain non-GAAP financial measures in this document. These financial measures are not defined under IFRS and should not be considered in isolation. The Company believes that these financial measures, together with financial measures determined in accordance with IFRS, provide investors with an improved ability to evaluate the underlying performance of the Company. The inclusion of these financial measures is meant to provide additional information and should not be used as a substitute for performance measures prepared in accordance with IFRS. These financial measures are not necessarily standard and therefore may not be comparable to other issuers.

All-in sustaining cost

All in sustaining cost is a non-GAAP financial measure calculated based on guidance published by the World Gold Council ("WGC"). The WGC is a market development organization for the gold industry and is an association whose membership comprises leading gold mining companies including Kinross. Although the WGC is not a mining industry regulatory organization, it worked closely with its member companies to develop these metrics. Adoption of the all-in sustaining cost metric is voluntary and not necessarily standard, and therefore, this measure presented by the Company may not be comparable to similar measures presented by other issuers. The Company believes that the all-in sustaining cost measure complements existing measures and ratios reported by Kinross.

All-in sustaining cost includes both operating and capital costs required to sustain gold production on an ongoing basis. Sustaining operating costs represent expenditures expected to be incurred at Great Bear that are considered necessary to maintain production. Sustaining capital represents expected capital expenditures comprising mine development costs, including capitalized waste, and ongoing replacement of mine equipment and other capital facilities, and does not include expected capital expenditures for major growth projects or enhancement capital for significant infrastructure improvements.

Cautionary statement on forward-looking information

All statements, other than statements of historical fact, contained or incorporated by reference in this news release including, but not limited to, any information as to the future financial or operating performance of Kinross, constitute "forward-looking information" or "forward-looking statements" within the meaning of certain securities laws, including the provisions of the Securities Act (Ontario) and the provisions for "safe harbor" under the United States Private Securities Litigation Reform Act of 1995 and are based on expectations, estimates and projections as of the date of this news release. Forward-looking statements contained in this news release include, without limitation, statements with respect to: the calculation of mineral resources at the project and the possibility of eventual economic extraction of minerals from the project; the identification of future mineral resources at the project; the Company's ability to convert existing mineral resources into categories of mineral resources or mineral reserves of increased geological confidence; the projected yearly gold production profile from both open pit and underground operations, all-in sustaining costs, mill throughput and average grades; future plans for exploration drilling; the projected economics of the project, including total gold sales, margins, taxes, average annual production, the net present value of the project, the internal rate of return on the project, project payback period, average yearly free cash flow, life of mine unit costs, projected mine life, the total initial capital and sustaining capital required; the project design, including the location of the tailings management facility, process plant, infrastructure area, stockpile areas, the anticipated advanced exploration site and the proposed open pit and underground mine plans; the project development timeline to production including the Company's work relating to its Impact Statement and permitting future phases of the project and development and construction of and production at the project, including the possibility of constructing either or both of an open pit and underground mines; the timing of and future prospects for exploration and any expansion of the project, including upside associated with the project's land package and via exploration at depth beneath the proposed underground mine; the potential for expanding the initial mineral resource and the potential for identifying additional mineralization in areas of intercepts and conceptual areas for extension and expansion; potential recovery rates or processing techniques; and the Company's plans to construct an exploration decline. The words "believe", "conceptual", "expect", "future", "plan", "potential", "progress", "prospective", "target", "view" and "upside" or variations of or similar such words and phrases or statements that certain actions, events or results "may", "could", "will" or "would" occur, and similar expressions identify forward-looking statements. Forward-looking statements are necessarily based upon a number of estimates and assumptions that, while considered reasonable by Kinross as of the date of such statements, are inherently subject to significant business, economic and competitive uncertainties and contingencies. The estimates, models and assumptions of Kinross referenced, contained or incorporated by reference in this news release, which may prove to be incorrect, include, but are not limited to, the various assumptions set forth herein and in our Annual Information Form dated March 27, 2024 and our full-year 2023 Management's Discussion and Analysis as well as: (1) there being no significant disruptions affecting the activities of the Company whether due to extreme weather events and other or related natural disasters, labour disruptions, supply disruptions, power disruptions, damage to equipment or otherwise; (2) permitting and development of the project being consistent with the Company's expectations; (3) political and legal developments in Ontario and Canada being consistent with its current expectations; (4) the accuracy of the current mineral resource estimates of the Company (including but not limited to ore tonnage and ore grade estimates); (5) certain price assumptions for gold and silver and foreign exchange rates; (6) Kinross' future relationship with the Wabauskang and Lac Seul First Nations and other Indigenous groups being consistent with the Company's expectations; and (7) inflation and prices for diesel, natural gas, fuel oil, electricity and other key supplies being approximately consistent with anticipated levels. Known and unknown factors could cause actual results to differ materially from those projected in the forward-looking statements. There can be no assurance that forward-looking statements will prove to be accurate, as actual results and future events could differ materially from those anticipated in such statements. Forward-looking statements are provided for the purpose of providing information about management's expectations and plans relating to the future. All of the forward-looking statements made in this news release are qualified by these cautionary statements and those made in our other filings with the securities regulators of Canada and the United States including, but not limited to, the cautionary statements made in the "Risk Factors" section of our Annual Information Form dated March 27, 2024, and the "Risk Analysis" section of our full year 2023 Management's Discussion & Analysis. These factors are not intended to represent a complete list of the factors that could affect Kinross. Kinross disclaims any intention or obligation to update or revise any forward-looking statements or to explain any material difference between subsequent actual events and such forward looking statements, except to the extent required by applicable law.

Certain forward-looking statements in this press release may also constitute a "financial outlook" within the meaning of applicable securities laws. A financial outlook involves statements about the Company's prospective financial performance, financial position or cash flows and is based on and subject to the assumptions about future economic conditions and courses of action and the risk factors described above in respect of forward-looking information generally, as well as any other specific assumptions and risk factors in relation to such financial outlook noted in this press release. Such assumptions are based on management's assessment of the relevant information currently available, and any financial outlook included in this press release is provided for the purpose of helping viewers understand the Company's current expectations and plans for the future. Viewers are cautioned that reliance on any financial outlook may not be appropriate for other purposes or in other circumstances and that the risk factors described above, or other factors may cause actual results to differ materially from any financial outlook. The actual results of the Company's operations will likely vary from the amounts set forth in any financial outlook and such variances may be material.

Other information

Where we say "we", "us", "our", the "Company", or "Kinross" in this news release, we mean Kinross Gold Corporation and/or one or more or all of its subsidiaries, as may be applicable.
The technical information about the Company's mineral properties contained in this news release has been prepared under the supervision of Mr. Nicos Pfeiffer who is a "qualified person" within the meaning of National Instrument 43-101.

Grassy Narrows First Nation
c/o Cavalluzzo
474 Bathurst Street, Suite 300,
Toronto, Ontario M5T 2S6
Attn: Grassy Narrows Lands Protection Team

Dear Grassy Narrows Lands Protection Team,

RE: Great Bear Mining Project - Preliminary Technical Review of the Mercury Study Plan dated December 2024

Introduction

Thank you for forwarding the Great Bear Project Mercury Study Plan by WSP Canada Inc., dated December 2024. This Study Plan is a response to the Tailored Impact Statement Guidelines (TISG) from the Impact Assessment Agency of Canada. The TISG requires a detailed investigation of mercury and methylmercury. This investigation includes interactions with sulphate some of which will be generated by proposed future mine wastes at the Great Bear Project at all relevant pH levels.

Grassy Narrows First Nation already has expertise on mercury and methylmercury. Therefore, my technical review here focuses on the portions of Section 3.4 (Methods for Forecasting Future Conditions) involving modelling within my areas of expertise. Section 3.4 begins:

> "The following sections outline the key data inputs and modeling approaches proposed to predict future conditions and potential changes from baseline levels, resulting from the Project's potential contributions to methylmercury production. Sulphate, mercury, and methylmercury concentrations in both mine site drainage and the receiving environment will be influenced by factors such as the geochemistry of ore and mine rock, the quantities and management of stockpiled materials, and the characteristics of the receiving waters."

The proposed models in Section 3.4 involve geochemistry including Metal Leaching and Acid Rock Drainage (ML-ARD or geochemical source terms), groundwater flow, and water quality as discussed in the following subsections of the Mercury Study Plan.

3.4.1 Geochemical Characterization
3.4.2 Groundwater Modelling
3.4.3 Mercury and Methylmercury Water Quality Modelling

As explained below, the proposed methods and models in these subsections of Section 3.4 are incorrect, misleading, and/or unacceptably ambiguous for assessing and predicting mercury and

sulphate on, beneath, and around the Great Bear Project. I expect the general effect of the proposed methods and models for the Mercury Study Plan will be to underestimate the leaching and transport of mercury, sulphate, and other metals and elements at the Great Bear Project.

Geochemical Characterization

Subsection 3.4.1 explains the methods that will be used to predict the aqueous concentrations and solid-phase levels for dozens of potential contaminants at the Great Bear Project, including sulphate, ML-ARD, and water quality at near-neutral pH.

This Study Plan states,

> "The sampling approach and testing methods for the geochemical investigations comply with ... guidance found within the Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND, 2009), which represents best practice and industry standard approaches and methodologies for ML/ARD sampling and characterization in Canada."

Kinross committed to the same approach and testing for Advanced Exploration at the Great Bear Project years ago, but fails to follow guidance in this federal Prediction Manual of best practice and industry standards[1]. Where Kinross did follow some guidance and detected potential for significant water-quality degradation and ML-ARD, Kinross decided this serious potential was not relevant to its Great Bear site. Where Kinross admitted to not following the guidance and using a non-recommended procedure that was cheaper, Kinross' rationale was that the non-recommended procedure was mentioned in the federal Prediction Manual as not recommended and thus Kinross was indeed following the federal Prediction Manual.

Kinross has committed to conducting many of the tests for geochemical characterization in this Subsection 3.4.1 as it did for Advanced Exploration at the Great Bear Project. However, as of early 2025, Kinross has not released most of the results for any geochemical testing.

Section 3.4.1 continues Kinross usage of the wrong analytical methods as it did for Advanced Exploration[1]. For example, Section 3.4.1 lists:

> "Solid phase elemental content analysis by aqua regia digestion and inductively coupled plasma-mass spectrometry scan"

However, Kinross fails to explain to non-technical readers that this will underestimate the amount of mercury in Great Bear mined materials including the walls of underground workings and pits, waste rock, overburden, soil, and tailings.

[1] MDAG. 2024. Review of Kinross Gold Responses to Grassy Narrows First Nation Concerns for Advanced Exploration, Concerning Metal Leaching, Acid Rock Drainage (ML-ARD), On-Site Contamination of Water, Fugitive Dust, and Hydrogeology in the ECA, PTTW, and Closure Plan Responses. Report for Grassy Narrows Lands Protection Team, dated September 5, 2024. 48 p.

This is because "aqua regia digestion" dissolves and analyzes only part of the mercury and many other elements in Great Bear mine materials, leaving behind an undetected and unknown amount of additional mercury and other elements. This is not appropriate under conditions and pathways such as fugitive dust to the environment, local-scale acidic conditions, animal inhalation, and comparisons to crustal abundances, which require "total digestion" of all mercury in a sample rather than only part of the mercury from partial "aqua regia digestion". Thus, based on the listing of methods in Section 3.4.1 for mercury, sulphate, and other elements, it is easy to overlook or miss the facts that these proposed methods are not appropriate, reliable, and safe for the Mercury Study.

Therefore, Grassy Narrows First Nation should understand that this Mercury Study Plan contains a program for Geochemical Characterization that matches that for Advanced Exploration, but Kinross has not been able to fulfill this program for Exploration to date after about two years of trying. Also, this geochemical characterization will use invalid and/or ambiguous methods that will underestimate the severity of mercury and sulphate issues at the Great Bear Project. As a result, I expect that Kinross will underestimate the important geochemical input that is critical for a reliable outcome from the proposed Mercury Study. If Kinross corrects the geochemical methods in the Mercury Study Plan to those appropriate to the Great Bear Project, then Advanced Exploration should be stopped because it is already based on invalid and/or ambiguous methods.

Groundwater Modelling

In Subsection 3.4.2, the Mercury Study Plan contains a description of the groundwater modelling that will be used to predict the flow of groundwater and likely the additional mercury loadings to the water-quality model discussed below. Similar to the Geochemical Characterization above, the procedure proposed for groundwater modelling is about the same as used for Advanced Exploration that is seriously flawed[1].

There are many errors in Kinross' modelling of groundwater flow at the Great Bear Project. Many reflect technical details that require relatively long explanations[1]. For example, groundwater modelling at the Great Bear Project apparently shows a high mound of free-standing groundwater above the land surface near Dixie Creek. This artificial and obviously wrongly modelling incorrectly restricts groundwater with mercury, sulphate, and other elements from travelling off the Great Bear site and into the surrounding environment around Dixie Creek.

Perhaps the easiest error to understand with Kinross' groundwater modelling, for both Advanced Exploration and the Mercury Study Plan, is the difference between "transient" and "steady state" groundwater modelling. Similar to surface water and many other environmental processes like temperature and rainfall, subsurface groundwater flow can shift and change daily, seasonally, yearly, over decades, and even longer due to climate change. Thus, the earth's environment is inherently "transient" through time, which can be important for defining flows and loadings of mercury, sulphate, and other elements.

Kinross does not model groundwater at the Great Bear Project using naturally transient conditions. Instead, Kinross only models groundwater at Great Bear with "steady state" conditions, where groundwater flows and loadings are constant all the time, every day, every season, every year, every decade, etc. For Advanced Exploration, at what point in the future was groundwater modelled? No one can say, but the obvious assumption is that it represents conditions a long time into the future. No one can say because Kinross continues to refuse transient modelling.

Groundwater modellers for Great Bear have stated that transient modelling is not needed despite having no transient data, no transient measurements, and no transient modelling[1]. I suspect that Kinross is strongly opposing transient groundwater modelling because it requires additional site measurements and parameters apparently not measured at the Great Bear Project.

Transient groundwater modelling at the Great Bear Project is seriously needed to understand better the impacts and effects on (1) groundwater inflows around the mine and (2) groundwater movement throughout all hydrogeologic layers and surrounding environment, as time passes. Kinross has pointed out that the effects of drought and climate change cannot be estimated, which is because only steady-state modelling was conducted.

Because steady-state modelling of some distant future but unknown time was modelled for Advanced Exploration, this is obviously the modelling that would also apply to proposed mining in the Mercury Study Plan. However, the steady-state modelling for Advanced Exploration was likely wrong but Kinross has not released the additional information from its steady-state model to confirm this.

During proposed exploration and later mining, groundwater will be drawn from all depths into the underground mine at least 500 meters (0.5 km) deep vertically. However, Kinross will release only the drawdown map for the uppermost 36 m of overburden, and not the remaining ~500 m vertical thickness of rock. This incorrectly implies (1) drawdown happens instantaneously for long lateral distances throughout the Great Bear site and (2) transient conditions are minor because they will only be up to 36m vertically.

In situations where groundwater levels will fluctuate more than 500 meters vertically, non-steady "transient" modelling is certainly needed. In fact, groundwater levels, forced by Kinross pumping, varying by roughly 500 m vertically (varying by roughly 0.5 kilometers below the land surface) at the Great Bear Project is one of the best examples of where transient groundwater modelling is critical for reliable and realistic flow directions and associated loadings of mercury, sulphate, and other elements. The proposed open pits at Great Bear will also lead to significant transient groundwater flows and geochemical loadings like mercury and sulphate closer to the land surface but are ignored by Kinross.

Additionally, Kinross misleads by indicating shallow contaminated groundwater will not escape to the environment but would be drawn into the pumped-down underground mine[1]. This is false at early times and only becomes reasonable after unknown longer times as steady-state conditions are approached. The lack of transient modelling prevents anyone from proving how long it will take to

reach steady-state conditions and prevent contaminated groundwater from escaping.

Based on this error alone of steady-state groundwater modelling, Section 3.4.2 of the Mercury Study Plan is remarkable in that it simply states,

> "These numerical groundwater flow models [of FEFLOW 7.2] consider three dimensional steady-state flow conditions and implement an equivalent porous media approach which is deemed sufficient for characterizing the overall groundwater flow regime at the scale of this analysis."

This is wrong, because FEFLOW 7.2 can also simulate transient conditions. Kinross is misleading readers here by not revealing the full capability of this groundwater model including transient modelling needed for the Mercury Study and for general impacts of the Project. In any case, it is clear that steady-state, always-the-same-and-not-varying groundwater modelling, for conditions at some distant but unknown time, will be used to unreliably simulate the critical groundwater pathways and loadings for mercury and sulphate at the Great Bear Project.

Furthermore, the second part of the quotation above on "equivalent porous media" deceptively hides another important flaw. Groundwater moving through irregular and scattered cracks (fractures) in Great Bear rock will be instead incorrectly modelled as smoothed layers like sand and gravel. Kinross has cryptically "deemed sufficient" this unrealistic modelling based on no data and no evidence that groundwater flow through fractured rock at Great Bear is like groundwater flow through sand, gravel, silt, etc. Without proof otherwise, the porous-media modelling planned for the Mercury Study is not "sufficient" and is plain wrong and misleading.

Therefore, Grassy Narrows First Nation should understand that this Mercury Study Plan contains a program for Groundwater Modelling that matches that for Advanced Exploration. The current groundwater modelling is unreliable and likely wrong in light of many incorrect and unjustified assumptions made by Kinross. The Mercury Study Plan shows these errors will be continued, including the false assumption that groundwater flow will be steady state during mining, being the same every day, every season, every year, every decade, etc. As a result, I expect that Kinross will underestimate the important groundwater flow leaving its Great Bear site. Along with problems with the proposed Geochemical Characterization discussed above, this will underestimate the loadings of mercury, sulphate, and other elements leaving the Great Bear site. This will preclude a reliable outcome from the proposed Mercury Study. If Kinross corrects the proposed groundwater modelling in the Mercury Study Plan, then Advanced Exploration should be stopped because it is already based on the misleading and wrong modelling.

Water-Quality Modelling

Section 3.4.3 on water-quality modelling explains that the model called GoldSim will be used for water-flow and water-quality modelling at the Great Bear Project. Here are some statements from Section 3.4.3 about the GoldSim model.

- GoldSim will "stimulate [sic] the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project".

- "The GoldSim model domain includes waterbodies potentially impacted by the Project within the PA, LSA and RSA."

It is not clear from these statements that GoldSim is not like models such as groundwater (see above) that simulate the movement and chemistry of waters (1) across a site-wide grid of mathematical elements or (2) along a grid of mathematical elements along lake or a creek like Dixie Creek where groundwater can alternately enter and exit the surface waterbodies over short distances.

Instead, GoldSim uses user-defined "compartments" or "conceptual boxes" such as one for the western portion of Dixie Creek near the Great Bear site and another for the eastern portion near the site. The human modellers then conceptually connect these two boxes and any other selected boxes in the GoldSim model to create "nodes". Then the modellers choose the inputs, outputs, and internal conditions and processes that they think apply to each box and node. This should include variable and transient conditions that exist at the Great Bear site over days, seasons, years, and decades, but we already know from the proposed groundwater modelling that transient conditions for at least one important pathway for mercury and sulphate will be ignored and thus will not reliable (see above).

Now it is clearer what Kinross means by saying,

> "Sulphate, mercury and methylmercury predictions will be generated for waterbodies represented by model nodes shown in Figure 3-2."

Thus, predictions for mercury and sulphate will be generated only at "nodes" that do not literally simulate waterbodies in their environmental complexity, but simply represent the "boxes" and "nodes" and internal conditions that Kinross chooses to assume, estimate, and simulate.

Figure 3-2 in the Mercury Study Plan shows that the Chukuni River will be modelled only at two nodes: CHK-1 immediately above the property boundary and CHK-2 immediately below the boundary. Therefore, everything above the property boundary in the Chukuni River will be simulated as a single "node" or "box" for which the modellers will define all the upstream physical, geochemical, and water-quality properties, likely with many simplifications and/or assumptions. Then the physical and chemical contributions from Dixie Creek Node DIX-5 will be "mixed" with Node CHK-1 to obtain predicted flows and concentrations at Node CHK-2, subject to currently unstated simplifications and/or assumptions possibly like adsorption on river-bed sediments or biological processes to remove additional mercury and sulphate from the water at CHK-2. Because of this "node" approach, important details like an initial dilution zone (a mixing zone) in the Chukuni River between Nodes CHK-1 and CHK-2 cannot be simulated in sufficient detail. This gives you some idea how the GoldSim model will "simulate" water flow and water quality at, beneath, and around the Great Bear site.

The GoldSim model for the Great Bear Project can be easily manipulated by the modellers but this is hidden from external inspection by Grassy Narrows First Nation. For example, the modellers can apply a condition where aqueous concentrations of mercury, sulphate, and other elements are allowed to decrease but are not allowed to increase as water "flows" through the boxes and nodes. Section 3.4.3 promises to "[p]rovide a clear description and rationale for model input parameters and assumptions". This is appropriate and important but in my experience I have never seen this

provided in sufficient detail for any GoldSim model.

Therefore, to understand how the GoldSim water-quality model for the Great Bear Project has been designed and manipulated through all of its boxes and nodes, and thus whether its results and predictions are reasonable, a relatively large amount of information on the GoldSim model will be needed from Kinross. I have not seen this provided in detail before, but it will be required for the Great Bear Mercury Study.

Conclusion

As explained above, the proposed methods and models in the subsections of Section 3.4 of the Mercury Study Plan are incorrect, misleading, and/or unacceptably ambiguous for assessing and predicting mercury and sulphate on, beneath, and around the Great Bear Project. I expect the general effect of the proposed methods and models for the Mercury Study Plan will be to underestimate the leaching and transport of mercury, sulphate, and other metals and elements at the Great Bear Project.

Sincerely,

Kevin A. Morin, Ph.D., P.Geo., L.Hydrogeo.

Re: Preliminary review of the Great Bear Project Mercury Plan, December 2024

1 Introduction

I have been asked to provide a preliminary review the Great Bear Project Mercury Study Plan (WSP, December 2024), and provide an Expert Opinion concerning the adequacy of the plan to protect receiving waters and biota from the direct and indirect effects of the proposed project. As there is little new information provided in this document, a substantial amount of this memo is derived from prior opinions and memos of mine that have reviewed other submissions from the Proponent. These are listed in materials referred.

2 Qualifications

I received my PhD in Geography from McGill University, Montreal, Canada in 1999 with a specialization in hydrology, mercury biogeochemistry, and wetland science. I was subsequently employed as a Professor at the University of Toronto Mississauga campus in Mississauga Ontario, Canada for 10 years, establishing an internationally recognized research program on hydrology and mercury in the environment. In 2010, I was recruited by the University of Western Ontario to the position of Professor and Canada Research Chair in Environment and Sustainability. I am considered an internationally recognized expert in the field of watershed biogeochemistry and the environmental cycling of mercury.

I have authored or co-authored over 100 peer-reviewed scientific papers and book chapters, and have made, or contributed to significant discoveries concerning the role of wetlands on the production and export of methylmercury (e.g. Branfireun et al., 1996; 1998; 1999; 2001; 2005; McCarter et al., 2017). I have been involved in high-impact state-of-the-science publications that have provided significant direction to the mercury research community (Harris et al., 2007; Munthe et al., 2007; Branfireun et al., 2020; Blanchfield et al., 2021). In addition to environmental biogeochemistry, research in my group has broadened to include the impacts of mercury on biota, including migratory birds (e.g. Ma et al., 2018a,b).

3 Summary of Opinions Concerning the Great Bear Project Mercury Study Plan

The Great Bear Project Mercury Study Plan provides a more comprehensive background discussion (Section 1.2) of mercury biogeochemistry than any previous document that I have reviewed from the project Proponent. In Prior submissions, the direct and indirect effects on mercury biogeochemistry of the proposed project have been dismissed, downplayed or ignored, so an increased acknowledgment of the link between sulphate loading from the proposed project from the Proponent is welcome. The presentation of the basics of mercury biogeochemistry is significantly more scientifically correct than the erroneous and misleading prior submissions from the Proponent indicating to me that there is effort being invested to coming up to speed about the current state-of-the-science mercury methylation, which I consider to be a central issue related to the proposed project. Indeed the Proponent acquiesces to the indisputable link between sulphate and mercury methylation, in contrast with the attempts to sew doubt found in prior submissions (Kinross Response to ANA Memo concerning

Great Bear Project AEX ECA Application, August 1, 2024), and goes so far as to acknowledge that arguments to apply site specific knowledge to setting mercury thresholds are valid. Despite this effort, there has surprisingly been no change in the interpretation of baseline data nor the proposed plan for effects monitoring for mercury or methylmercury – I find the same errors in a more attractive wrapper. The facts related to the inadequacy of the background data, sampling frequency, analytical methods, and misrepresentation of the receiving water body receiving effluent (Chukuni River) remain in this document, and evidence-based corrections in prior submissions by ANA have not been acknowledged or addressed, although many are now hidden by vague and over-generalized language. The only salient new information in the Mercury Study Plan is the Proponent's suggested application of a model (GoldSim) to predict changes in mercury and methylmercury as a result of the project. This model is a wholly inappropriate framework for this purpose and cannot provide the information that the Proponent suggests. As such, none of what is presented in this plan addresses the TISG requirement:

"Of particular note, the potential for project contributions to methylmercury production in downstream watersheds requires a detailed and robust analysis. The proponent must submit a study plan to the Agency with sufficient time to facilitate a review by experts and interested parties and to inform the studies undertaken. This includes establishing baseline methodology and effects assessment methodology related to methylmercury as outlined in section 8.6 Groundwater and Surface Water and 8.8 Fish and Fish Habitat."

This requirement is not met because none of the inadequacies of background data or future monitoring that have been previously identified have been addressed let alone acknowledged, and important information from prior documents was omitted which would permit a complete review by experts and interested parties who do not have full knowledge of what has been proposed in prior submissions from the Proponent. As many of these issues have been addressed in prior submissions from ANA, my opinions regarding the Great Bear Project Mercury Study Plan are reiterations of prior concerns with the exception of the discussion of the inappropriateness of GoldSim, which was informed by written and oral testimony that I presented for another case (and was supported by the US Environmental Protection Agency and Army Corps of Engineers).

It is my opinion that:

1) The selective reliance on achieving on and off site water quality that complies with water quality guidelines (CCME) inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota.

2) The background data collected as part of the baseline studies for this project are largely erroneous or their interpretation is flawed, rendering them neither comprehensive nor sufficient to detect whether the project will have measurable impacts on fish mercury levels in the future.

3) The assimilative capacity of the receiving waters (Chukuni River) as a mitigation strategy for excess sulphate loading is not supported by available data. As this is the only measure that has been proposed to address the indirect downstream effect of sulphate-related methylmercury production, there is no evidence that other adverse downstream effects can be avoided.

4) The model that the Proponent indicates will be used to predict changes in mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish (including assessment bioaccumulation / bio-magnification pathways) can technically deliver none of these outcomes.

4 Opinion 1: The selective reliance on achieving on and off site water quality that complies with water quality guidelines (CCME) in inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota.

Section 2.2.1 of the Great Bear Project Mercury Plan States the following:

> Existing baseline mercury and methylmercury concentrations in surface water and groundwater are compared against applicable guidelines for the protection of aquatic life as well as health-based drinking water quality guidelines, including the:
>
> −CCME guideline for total mercury for the protection of aquatic life (26 ng/L)
> −CCME guideline for methylmercury for the protection of aquatic life **(0.04 ng/L (sic)**
> −Canadian drinking water quality for mercury (1,000 ng/L)
> −United States Environmental Protection Agency (US EPA 1997) criterion of 0.05 ng/L for filtered methylmercury in water for the protection of fish-eating wildlife species

Disregarding the fact that the authors of the report surprisingly misstate the CCME guideline for methylmercury (it is 4 ng/L not 0.04, although 0.04 would be more scientifically justifiable), the statement that the data from the proposed project will be "compared against" any criteria is meaningless, because one may compare an apple to an orange; no intent, threshold, nor trigger value is indicated or even implied by this language. Despite quoting the more reasonable US EPA criterion of 0.05 ng/L methylmercury for the protection of fish-eating wildlife, prior documents submitted for this project indicate clearly that the Proponent intends (and has been approved by the Ontario MECP) to apply the CCME guideline the project from a compliance standpoint, so the reader should presume that the CCME values are the regulatory thresholds being applied by this Mercury Plan, rather than merely comparisons. As I have stated in prior opinions, there is no other way to characterize the CCME guideline values for mercury and methylmercury as anything but useless for the protection of fish consumers, and even if discharges or indirect effects were a fraction of these guideline limits there would be significant potential for downstream impairments of aquatic resources. For example, the CCME Criterion for (Total) mercury is 26 ng/L, which is a value (developed from a 1991 protocol) for the **direct** protection of aquatic life. Despite being profoundly outdated, the CCME document provides valuable commentary that is all too frequently ignored when setting regulatory criteria based on this single value, including "*The protocol **does not** address exposure through **food or bioaccumulation** to higher trophic levels*", and "*if the ultimate management objective for mercury is to protect high trophic level aquatic life and/or those wildlife that prey on aquatic life, **more stringent site-specific application** of these water quality guidelines may be necessary*" (CCME, 2003, p.2; **emphasis mine**).

Although the Province of Ontario is silent on the issue of any other water quality guidelines for mercury, other jurisdictions have been more engaged with revising their mercury and

methylmercury based on best available science at the time. British Columbia explicitly acknowledges the limitations of the CCMEs guidelines, stating "It should be noted that the CCME (2000) in developing guidelines for fresh and marine waters did not consider bioaccumulation effects per se, but based their guidelines on **chronic toxicity**. They caution that the guidelines that they have developed 'may not protect wildlife that consume aquatic life'." (British Columbia Ministry of Environment and Lands, 2001; emphasis mine). We may reasonably extend the statement about consumers of aquatic life to humans. Despite the document being nearly as old as the original CCME guidance, BC takes the interesting approach of defining the water quality guideline to protect wildlife for total mercury by scaling it as a function of the percentage of total mercury that is methylmercury, acknowledging that methylmercury is the only form of mercury that bioaccumulates and biomagnifies in wildlife. Their Table 5 indicates that only in environments where methylmercury is largely not being formed would the CCME guideline of 26 ng/L for total mercury be remotely reasonable for fish consumers to be protected. In environments where methylmercury makes up an increasing fraction of total mercury, the allowable amount of total mercury decreases proportionally with the %methylmercury in the system. At 8% of total mercury as methylmercury, the guideline for total mercury is 1.25 ng/L. Even at 8% methylmercury the BC guideline total mercury value is below the detection limit of the technique that the Proponent declares adequate for the purposes of monitoring (DL of ~ 5 ng/L). The Proponent states in this document (as I provided to them in prior submissions) that that % methylmercury in surface waters of the proposed project can exceed 14% (using their own sparse data), translating to a guideline concentration of a mere 0.72 ng/L for the protection of wildlife consuming aquatic life. Despite the BC document being nearly 25 years old, the rationale for their mercury criteria is logical, and recognize the fact that even low levels of mercury in the environment can bioaccumulate and biomagnify to hazardous levels for fish consumers if the landscape has high methylmercury production potential. It is clear that current conditions in surface waters in the project area already exceed this criteria, meaning that **any** cumulative effect would be in exceedance of BC criteria for mercury in freshwater.

I find it impossible to accept any generalized guideline for mercury or methylmercury in aquatic environments, and instead advise site specific assessment for appropriate threshold levels (which the CCME also explicitly does in their 2003 document, but never seems to be considered). An acceptance of this project mercury plan adhering to the CCME guidance for mercury and methylmercury threshold concentrations for direct and indirect effects is effectively a license to impair downstream resources given the low concentrations of mercury identified by the Proponent through limited baseline sampling. Site specific criterion for mercury and methylmercury must be required here, and derived from **appropriate** baseline data – scant little of which currently exist (see Opinion 2).

5 Opinion 2: The background data collected as part of the baseline studies for this project are largely erroneous or their interpretation is flawed, rendering them neither comprehensive nor sufficient to detect whether the project will have measurable impacts on fish mercury levels in the future.

In the context of the protection of fish consumers, nearly all of the background data for total mercury are useless and stated incorrectly. All of the "data" that are reported in Table 2.10 of "Attachment 4 - Surface and Groundwater Technical Supporting Document" (March 2024) for total mercury are not data at all, but the reporting detection limits of the contract laboratory.

The background mercury data in water (with the exception of the handful of appropriate trace mercury and methylmercury analyses that were conducted by Flett Research) **is incorrect**. The data provided for mercury **are not data** – they are detection limits of the inappropriate technique used to do element scans by inductively coupled plasma – mass spectrometry (ICP-MS). ICP-MS in a standard configuration cannot generate data for mercury with appropriate detection limits (despite the Proponent's assertion to the contrary in the Mercury Plan). Moreover, the Proponent treats these detection limit placeholders as data – **these are not data.** If the contract laboratory reported these values as data, then they are not operating in compliance with ISO 17025 protocols. If the Proponent substituted detection limits for samples reported to be below the detection limit by the contract lab, then this is not correct procedure and should be stated as such. In both cases, a serious lack of oversight and understanding of analytical results is clear as **these are not data**. There is also insufficient data for methylmercury in surface water as this critical parameter was only measured sparsely as part of the baseline monitoring program. As a result, there is virtually no background data for mercury in surface waters for the project area, nor is there sufficient monitoring in the proposed plan because the appropriate trace mercury and methylmercury monitoring is only proposed at select locations and at a frequency that is insufficient to detect change over time, and with highly inappropriate threshold levels that are orders of magnitude above the levels at which adverse effects will occur.

Further investigation into the baseline monitoring data provided in Attachment 4 of the AEX-ECA application which contains all of the background data cited by the Proponent in the Mercury Plan also reveals that the **concentrations reported for sulphate were also erroneous** up until May of 2023 when the Proponent either changed analytical methods or laboratories, or incorrect instrument operation was corrected. From 2021-06-03 to 2023-03-30, we find data that are reported with no precision (i.e. no decimal place) and spuriously range from values of 1 to 11. I know of no analytical technique that would report concentrations like this (we see similarly erroneous data for parameters such as Chloride, TSS, TDS). The clearest evidence to me that this data is no better than random is the value of 7 mg/l on 2022-12-15, followed by a value of 1 mg/L four days later on 2022-12-19. Given that there was no appreciable change in river flow over this time, **these data are erroneous and cannot be used**. There is similar randomness in other parameters. The fact that the average concentrations that are reported directly in the Appendix are substantially different for the three stations on the Chukuni River should have been the first indication that there was a data quality problem.

Notably, the data quality changes substantially in May 2023, with two decimal place precision and a much more realistic range of concentrations (4.18 – 6.30 mg/L). Other parameters also show this step change in data quality. There was obviously a change in technique or in the contract laboratory being used that was not documented, which is contrary to best practices at the very least.

Other variables reported are also suspect up until this date as many of the physical parameters (e.g. TDS, TSS) and nutrient data ($N0_2$), contain inexplicable values, change in quality, or are dropped completely (e.g. NO_3-$N0_4$-T). The failure to note and censor these erroneous data is inexplicable – to use them to calculate descriptive statistics is inexcusable. For these variables (including sulphate) there are only 8-9 usable data points for all of the stations reported (including the Chukuni River).

The Mercury Plan makes reference to comprehensive background data about mercury and sulphate that will inform modelling efforts and trigger undefined actions should they change. One cannot numerically model concentrations of "below the detection limit". The reality is that the background data is neither "comprehensive" nor "sufficient" by any reasonable definition, and the approval of a Mercury Plan such as this is license to both proceed blind with respect to the site specific mercury conditions, as well as condone the continued use of an inappropriate analytical approach (despite the Proponent's statement to the contrary) that will reliably generate non-data that cannot capture trends in mercury concentrations across most of the sampling sites in the project area.

6 **Opinion 3: The assimilative capacity of the receiving waters (Chukuni River) as a mitigation strategy for excess sulphate loading is not supported by available data. As this is the only measure that has been proposed to address the indirect downstream effect of sulphate-related methylmercury production, there is no evidence that other adverse downstream effects can be avoided.**

Similar to the comparison to various mercury guidelines discussed above, the Proponent outlines in the Mercury Plan a range of sulphate mitigation measures that are being "considered" to address the issue of sulphate loading to sites of mercury methylation (Section 3.3). The primary mitigation measure outlined is to not discharge sulphate directly into sites with high methylation potential (e.g. wetlands). I am not sure that this constitutes a mitigation measure because of the obvious environmental consequence of doing so. Other measures being "considered" include various tailings management strategies and management of sulphate-bearing runoff. In the middle of the list is the **only** option that has been discussed and justified by the Proponent in all prior submissions:

"Discharging treated effluent to a large receiving watercourse (Chukuni River) that has a high oxygenation level and high assimilative capacity."

This 'mitigation strategy' has been commented on by myself and other experts in prior submissions, however this single sentence contains so much misleading information that it is worth breaking down here, making reference to the much more detailed discussion found in prior expert submissions.

1) **Treated effluent:** Indeed the Proponent has outlined strategies for treating effluent to be discharged to the Chukuni River, however none of the treatment technologies proposed target sulphate at all. Sulphate production from overburden and waste rock could be substantially greater than the Proponent states. Given that groundwater contributes nearly 80% of the total water outflows, 25% of groundwater samples (75^{th} percentile) from many locations in the project area had sulphate concentrations well in excess of 10 mg/L (Appendix B, Table 3 AEX-ECA Application), and the water treatment technology outlined by the Proponent has no capacity to remove sulphate, it would seem that the Proponent's 'expected' case of 10 mg/L sulphate is not just unlikely, but nearly impossible to achieve without even considering the potential for additional sulphate sources due to operations. Indeed without any additional treatment the Proponents 'extreme' case is likely a gross underestimate. With only gypsum saturation ultimately controlling sulphate solubility, sulphate concentrations in the range of 1000-1500 mg/L may be expected and are in fact, typical of many mine sites with oxidizing sulphide minerals like pyrite.

2) **Large watercourse:** This is of course a relative statement however a 20-year median annual discharge of 26.5 m^3/s is objectively a substantial flow. However as I have outlined in prior memos (Branfireun Review of Kinross Response to ANA Memo concerning Great Bear Project AEX ECA Application, August 1, 2024; October 7, 2024), median or mean statistics do not tell the whole story about assimilative capacity, despite the Proponent utilizing the simple numerical average of the entire daily discharge record (which upward biases the value) for all of their dilution scenarios presented in prior submissions to justify assimilative capacity. In the context of dilution of an environmentally relevant chemical, it is more relevant and protective to explore the lower ranges of flow, since it is at these levels that the river has less assimilative capacity and adverse effects are more likely. The 20-year average 25th percentile value is 14.2 m^3/s, meaning that for a full quarter of the year (which would include the relevant summer low flows when biogeochemical activity including methylation would be the highest), flows in the river are equal to or less than this value. The 20-year average minimum flows are only 5.7 m^3/s; more than 5 times lower than the discharge value that the Proponent used to calculate dilution. I argue that this is a more appropriate 'extreme' case discharge value to use, however it is notable that **the record contains a period of zero flow conditions in 2011 – a condition under which effluent discharge would make up 100% of river flow and would be completely undiluted (i.e. the river has zero assimilative capacity)**. 2023 was among the lowest flow years in the last 20, and the central tendency of the river discharge over that period is toward lower, and less variable flow. If the 2023 flow statistics (median, 25th percentile, and minimum flows of 13.5, 6.6 and 3.1 m^3/s are reflective of future drier conditions driven by climate change, then the use of a single value of average flow that is 10x greater than this low flow condition to calculate effluent dilution and demonstrate assimilative capacity is clearly not protective by any definition.

3) **High oxygenation level:** The Proponent has frequently made the argument that oxygenated waters in the receiving reach of the Chukuni River preclude negative effects of sulphate addition because sulphate reduction would not occur. This statement is misleading, as I could visit the most methylmercury contaminated lake in Ontario (Clay Lake) in August, measure surface water oxygen levels and declare it oxygenated. This would be ignoring the anoxic bottom waters and sediments where very high levels of methylmercury are formed. Of course, rivers do not stratify but it is well documented that they can have anaerobic sediments, biofilms and hyporheic zones where sulphate reduction and methylation can occur (despite having a well-mixed water column above). The biogeochemical status of the immediate receiving river reach is actually not the biggest issue here, it is the methylation potential of downstream waters where this well-oxygenated river will deliver sulphate that may be many times in excess of background levels.

Pakwash Lake is the first lake downstream of the proposed effluent discharge, and already has **five** fish species that have restricted consumption advisories due to mercury contamination (https://www.ontario.ca/page/fish-consumption-report?id=50459330) indicating that any further loading of methylmercury, or enhancement of the methylating process either in the lake or upstream would amplify an existing environmental degradation.

Whether the fish species with tissue mercury exceedances in Pakwash Lake immediately downstream of the proposed operation derive their methylmercury from Chukuni riverbank wetlands, river littoral sediments, biofilms or periphyton, anoxic profundal lake sediments, or anoxic hypolimnetic waters during stratification is actually irrelevant – methylmercury is produced in the aquatic environment because it is found in fish in downstream receiving waters

and it is dependent on the activity of sulphate-reducing bacteria, which are dependent on available sulphate. To have that many species with mercury consumption advisories confirms that this is a mercury sensitive environment with high mercury methylation potential.

4) **High assimilative capacity:** The argument was been made that additional sulphate might not enhance methylation in the receiving reach because it is oxygenated, but the Proponent has further argued that the proposed operation will not measurably increase sulphate in the Chukuni River and downstream receiving waters because of the dilution of the operation's effluent by the large flows of the Chakuni River (where dilution is used synonymously with assimilative capacity). All of the above points outline how the Proponent has arrived at the conclusion of high assimilative capacity through the application of erroneous/incorrect data, inappropriate analyses of river flows, and untested estimates of sulphate loading from project effluent, none of which is bounded by uncertainty. I have numerically laid out the potentially dire sulphate concentrations that may arise as a result of low flows combined with higher than stated effluent sulphate concentrations/volumes, should the reader choose to explore this more fully (Branfireun Review of Kinross Response to ANA Memo concerning Great Bear Project AEX ECA Application, August 1, 2024; October 7, 2024).

7 Opinion 4: The model that the proponent indicates will be used to predict changes in mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish (including assessment of bioaccumulation / bio-magnification pathways) cannot technically deliver any of these outcomes.

In the Great Bear Project Mercury Plan Section 3.4.3, the Proponent states that the GoldSim software modelling package will be used to "stimulate ***(sic)*** the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project." Without substantiation, they go on to state that "GoldSim has been extensively and successfully applied to simulate complex water resource management, mining operation, contaminant transport, and waste management projects and represents a robust industry-standard modelling software." Although I do not disagree that GoldSim has been widely applied to various industry problems I cannot speak to its success. I can say that it does not appear to ever have been applied to an environmental mercury speciation scenario. There is a clear reason for this – GoldSim is fundamentally (even with its CT submodel) a non-reactive mass-balance model that cannot incorporate mechanistic sorption/desorption reactions along flowpaths, the biomethylation process, nor the complex interaction between mercury and sulphate. As such, the model proposed can never be successfully applied in the manner that is proposed. A mass balance model *cannot* by definition incorporate mechanistically the input and removal processes for mercury, and *cannot* address the biogeochemical aspects of mercury methylation across the landscape which are at the root of the potential impacts associated with the Great Bear proposal. The reason why mass balance models are used for solutes (and can work for solutes that are conservative in water) is because they are simple to apply quickly and require little parameterization (i.e. are inexpensive to implement). Indeed they can have value to evaluate simple "what if" scenarios. However, being cheaper and easier to use is not sufficient justification for taking a naïve approach to evaluating possible environmental risks in a region of extreme mercury sensitivity, when much more defensible approaches exist, including models for watershed-steam mercury dynamics. On page 17 of the Mercury Plan, the authors state that GoldSim is used because it provides "a clear description and rationale for model input parameters and assumptions." I have seen this language used in other cases that I have opined about, with the implication being that GoldSim is somehow MORE clear in its description and

rationale of input parameters and assumptions than other models (i.e. superior). This seems to be popular but baseless justification, as it implies that it is somehow more transparent than other model frameworks.

The statement that the mass balance models like GoldSim are transparent with respect to data inputs is true, in that it is true that *any* model is transparent with respect to data inputs because one must know what the data inputs are in order to run the model (a non sequitur). What is also true of any model is the adage of "garbage in, garbage out." The definition of input parameters and stated variables is always required in any model, as is the establishment of boundary conditions and mechanisms that reflect the best available science. In the case of the Great Bear Project, we have a virtual absence of useable data for baseline water quality (see above), which means that we are at a loss for values for the very input parameters that are required.

The Great Bear Project Mercury Plan reaches even farther by stating that "Results of GoldSim modelling for surface water and sediment quality, described above, will be used to forecast and assess potential effects on fish mercury concentrations in downstream watersheds. Both small and large-bodied fish will be considered in this assessment." My understanding of GoldSim is that it uses the sediment compartment to model water chemistry, not the other way around, so to suggest that GoldSim can be used predictably for the sediment compartment is unrealistic beyond simple mass transfer, despite the importance of the sediment compartment for net methylation. More problematic is the leap of faith between whatever output is provided by GoldSim and a prediction of methylmercury concentrations in biota. There is no evidence of any such effort being successfully reported in the public domain; if the Proponent has advanced the science in this area then I would welcome an opportunity to review their efforts in this regard as it would mark a major breakthrough in modelling mercury biogeochemistry and biotic uptake. I suspect that this is not the case, since the means by which this is to be accomplished is apparently "changes in fish body burden mercury concentrations is considered to be the forecasted methylmercury concentration in the water column, as determined by the water quality model." I am not sure who "considered" this relationship, however it was not someone with a modest scientific understanding of the controls on fish tissue MeHg concentrations – such a simplistic forecasting relationship does not exist, and this is in addition to the fact that GoldSim cannot predict methylmercury concentrations in the first place.

8 Other Errors, Omissions and Concluding Remarks

There are other problematic statements throughout the Mercury Plan that are used to downplay the potential impacts of the project do not align with scientific facts. The statement "For example, SRB-induced mercury methylation could occur in areas of organic soils peripheral to the rock stockpiles; however, methylmercury production beneath rock stockpiles can be limited by low temperatures at the base of the stockpiles which will inhibit SRB activity." is patently false given that the SRB can be quite active at temperatures just above freezing (e.g. Fortin et al., 2000).

We have all kinds of details on sample handling and Quality Assurance/Quality Control procedures in Section 2.2.1 that convey attention to detail and rigour, however a statement about sampling frequency is carefully worded so that the inadequacy of the water quality sampling is not apparent.

Baseline surface water quality sampling generally occurs monthly to characterize seasonal variability in water quality, providing flow is present and that the monitoring site can be safely accessed. (GBP Mercury Plan, p.5)

This statement fails to identify which solutes will be measured from this 'generally' monthly sampling, however in prior documents, the Proponent has clearly indicated that low detection level mercury and methylmercury sampling will only be done at only **half of the sampling sites**, and are only to be taken **quarterly (4 times per year)**. This low frequency of sampling of the only mercury data of utility is insufficient to statistically detect change until that change is so substantial that its effects would be irreversible. Since all of the other mercury sampling will be subject to an inappropriate analytical technique that will mostly return non-detects, the proposed monitoring programs are effectively designed to avoid change detection and I expanded on this in a prior memo (Branfireun to Esmonde, on Advanced Exploration Program (AEX) Environmental Compliance Approval - Industrial Sewage Works (ECA – ISW) July 5, 2024).

Here, we see the assembly of a house of cards by the Proponent. We have a water quality model that is not capable of predicting mercury biogeochemical processes, and that is dependent on background data and proposed monitoring that is insufficient. The outcome will be the inevitable future conclusion by the Proponent that the combination has led to an inability to adequately predict changes in methylmercury concentrations in fish because of 'uncertainties' in GoldSim output, and 'unforeseen complexities' in coupling abiotic and biotic compartments. The reality is that these uncertainties and complexities are completely foreseeable as outlined here. The consideration of the December 2024 Mercury Plan as anything other than deficient will excuse the Proponent's future failure to predict the impact of the proposed development from a mercury perspective because of the appearance of due diligence at this stage of the process. I conclude that the TISG's requirement that the Proponent provide *a detailed and robust analysis on the potential for project contributions to methylmercury production in downstream watersheds* has not been met based on the information provided in their Mercury Plan.

Water Quality

Ambient Water Quality Guidelines for Mercury

Overview Report — First Update

Prepared pursuant to Section 2(e) of the
Environment Management Act, 1981

Original signed by Margaret Eckenfelder
Assistant Deputy Minister
Environment and Lands HQ Division
February, 2001

Summary

This report is one in a series that establishes ambient water quality guidelines for British Columbia. The guidelines are safe conditions or levels of contaminants, applicable province-wide, which are set to protect various water uses.

This report updates the 1989 BC Environment guidelines for total mercury (THg) by providing revised water quality guidelines to protect aquatic life from chronic effects of mercury. This was deemed to be necessary since the Canadian Council of Ministers of the Environment (CCME) have recently developed guidelines for mercury in the water column to protect aquatic life and in the flesh of aquatic life to protect wildlife. The report also outlines water quality guidelines to protect avian wildlife feeding on aquatic organisms. The updated guidelines are consistent with the CCME tissue residue guideline to protect wildlife from methyl mercury (MeHg) in their diet. The guidelines for livestock, irrigation and recreation, are unchanged from in the 1989 report. The guidelines are summarized in Table 1, Table 2, and Table 3.

Table 1: Summary of Water Quality Guidelines for Mercury

Water Use	30-d av. Conc.* (µg/L THg)	Maximum Conc. (µg/L THg)
Source Drinking Water	See Source Drinking Water Quality Guidelines: https://www2.gov.bc.ca/assets/download/1F11ABD2CBD24EB09A70B89AB50CE6B0	
Wildlife and Aquatic Life (Freshwater Estuarine and Marine)+ When MeHg = 0.5% of THg When MeHg = 1.0% of THg When MeHg = 8.0% of THg	 0.02 0.01 0.00125	None proposed
Irrigation Water Supplies	None proposed	2.0
Livestock Water	None proposed	3.0

* The 30-day average is based on five weekly samples taken in a period of 30 days.
+ If natural levels exceed the guidelines for aquatic life, then any increase allowed above the natural levels should be based on site-specific data.

Table 2: Tissue Residue Guidelines to Protect Wildlife from Mercury Toxicity

The concentration of methyl Hg in fish or shellfish consumed by wildlife should not exceed 0.033 µg/g wet weight.

Preface

THE MINISTRY OF ENVIRONMENT, LANDS AND PARKS (now called Ministry of Water, Land and Air Protection) develops province-wide ambient water quality guidelines for variables that are important in the surface waters of British Columbia. This work has the following goals:

1. to provide guidelines for the evaluation of data on water, sediment, and biota

The definition of a guideline is:

A maximum and/or a minimum value for a physical, chemical or biological characteristic of water, sediment or biota, which should not be exceeded to prevent specified detrimental effects from occurring to a water use, including aquatic life, under specified environmental conditions.

The guidelines are province-wide in application, are use-specific, and are developed for some or all of the following specific water uses:

- Raw drinking and public water supply
- Aquatic life
- Wildlife
- Agriculture (livestock watering and irrigation)
- Recreation and aesthetics

The guidelines are set after considering the scientific literature, guidelines from other jurisdictions, and general conditions in British Columbia. The scientific literature gives information on the effects of toxicants on various life forms. This information is not always conclusive because it is usually based on laboratory work which, at best, only approximates actual field conditions. To compensate for this uncertainty, guidelines have built-in safety factors which are conservative but reflect natural background conditions in the province.

Guidelines are subject to review and revision as new information becomes available, or as other circumstances dictate.

The guidelines apply to the ambient raw water source before it is diverted or treated for domestic use.

The Ministry of Health regulates the quality of water for domestic use after it is treated and delivered by a water purveyor.

Guidelines relating to public health at bathing beaches are the same as those used by the Ministry of Health which regulates the recreation and aesthetic use.

Introduction

Mercury is a non-essential element for plants and animals. However, metallic mercury is widely used in industry for the manufacture of chemicals, electrical equipment, power generation, dental amalgams and metallurgical gold. The mercurial compounds have found applications in paints, drywall compounds, scientific supplies, pharmaceuticals, fungicides and bactricides.

Mercury is found naturally in the earth crust, rocks, minerals, and coal and base metal deposits. Areas of high mercury content associated with zones of instability and volcanic and thermal activity have been found over the globe.

Many natural and anthropogenic sources contribute to environmental mercury loading. In the environment, mercury can exist in both organic and inorganic forms. Methyl mercury (MeHg), the most toxic form of mercury, tends to bioaccumulate and biomagnify in the aquatic food chain. Piscivorous mammals, fish and birds accumulate most of their body burden through diet.

Mercury is known to damage renal, nervous, reproductive, and developmental systems. The chemical form of mercury and route of entry are important determinants of its toxicity. Ingestion of inorganic mercury is primarily responsible for erosion of intestinal tracts and kidney damage in both animals and humans. Methyl mercury and short-chain organic mercurials destroy neuronal cells in areas of central nervous systems concerned with sensory and co-ordination functions.

In British Columbia, economic grade deposits of mercury are commonly associated with sedimentary rocks such as limestone and sandstone of the Palaezoic to Recent age. The province's richest mercury deposits are in the Pinchi Lake fault zone which extends from Fort St. James northwest to the Omineca River. Other major areas of mercury mineralization in British Columbia include Kamloops Lake, Bridge River, and Yalakom River.

The concentration of mercury in natural waters is generally low. However, elevated concentrations of mercury have been reported in British Columbia in areas contaminated by the industrial activity (e.g., Squamish) and where extensive mercury mineralization has occurred.

Historical mercury concentrations should be viewed with caution. Results from cleaner laboratory analytical methods with lower detection limits show that background mercury concentrations are lower than previously thought. Older high values may be the artifacts of high detection limits and artificial contamination during measurement.

Recommended Guidelines

Table 1 summarizes all guideline values including those that have been updated. This was deemed to be necessary since the Canadian Council of Ministers of the Environment (CCME) have recently developed guidelines for mercury in the water column to protect aquatic life and in the flesh of aquatic life to protect wildlife. There is obviously a need to reconcile all these guideline values in one document for the benefit of resource managers.

1. SOURCE DRINKING WATER

See the Source Drinking Water Quality Guidelines: Guideline Summary Document

https://www2.gov.bc.ca/assets/download/1F11ABD2CBD24EB09A70B89AB50CE6B0

2. AQUATIC LIFE (FRESHWATER, ESTUARINE AND MARINE)

These guidelines replace the 1989 BC Environment guidelines for fresh, marine and estuarine waters.

(a) The 30-day average guidelines for marine, estuarine and fresh waters are the same, due to the facts that:

- the bioaccumulation potential of mercury in marine and freshwater food chain is similar; and
- both are based on the 1999 CCME recommended tissue residue guideline to protect the most sensitive consumers of aquatic life (e.g., avian species).

The average concentration of total mercury in water as measured over a 30-day period (based on five weekly samples) should not exceed 0.02 ug/L when the methyl mercury (MeHg) constitutes less than or equal to 0.5% of the total mercury concentration. When the proportion of MeHg is greater than 0.5%, the guideline should be adjusted as indicated in the Table 3 below. The rationale for the graduated guideline is the fact that MeHg concentrations may vary in the environment. For example if the percent of MeHg is 11% the guideline would be calculated by the following equation:

0.1ng MeHg/L (WQGwl *see below in rationale section*) ÷ 0.11 (i.e. the % MeHg)
= 0.9 (guideline ng/L total Hg)

Table 3: The Total Hg Guideline as a Function of the Percentage of Methyl Mercury

% MeHg (of total Hg)	Guideline (ng/L total Hg)
0.5	20.0 ng/L
1.0	10.0 ng/L
2.5	4.0 ng/L
5.0	2.0 ng/L

These levels will protect freshwater aquatic life from chronic effects of mercury. They will also prevent undesirable accumulation of mercury from water to the food chain that may harm the most sensitive consumers (e.g., avian species) of aquatic life.

Rationale:

The following assumptions were made to update the 30-day average guideline to protect from mercury bioaccumulation in fish to a level that may harm wildlife consuming the mercury-contaminated fish:

All mercury in fish tissue is in the methylated form. This conclusion is consistent with observations made by researchers in the literature.

The MeHg bioaccumulation factor at a higher trophic level (level 3 or fish consumed by avian species) is 320,000 on wet-weight (BAF_{3ww}) basis or 1,600,000 on dry-weight (BAF_{3dw}) basis. This BAF is consistent with the US EPA recommended value and values observed in Squamish, British Columbia.

Based on recommended level of methyl mercury at 33 µg/kg wet-weight (diet) and the methyl mercury BAF_{3ww} of 320,000, the acceptable concentration in water for the protection of wildlife consuming fish can be estimated as follows:

$$WQGwl = (33\ \mu g\ MeHg\ kg^{-1} \times 1000\ mg/\mu g) / 320{,}000 = 0.1\ ng\ MeHg/L$$

(where WQGwl is the water quality guideline to protect wildlife)

Table 5 below expresses WQGwl in terms of the comparable THg levels for various percentages of MeHg as a function of THg.

Table 5. WQGwl In Terms of the Comparable THg Levels for Various Percentages of MeHg as a Function of THg

% MeHg (of total Hg)	WQGwl (ng/L total Hg)
0.5	20.0 ng/L
1.0	10.0 ng/L
2.5	4.0 ng/L
8.0	1.25 ng/L

This analysis suggests that the 1989 BC Environment's 30-day average guideline of 0.02 mg/L (or 20 ng/L) total mercury is valid as long as MeHg is less than or equal to 0.5% of the total mercury concentration. Appropriate water quality guidelines for MeHg concentrations other than those specified in the above table can be determined using a linear relationship between WQGwl and MeHg (%).

It should be noted that the CCME (2000) in developing guidelines for fresh and marine waters did not consider bioaccumulation effects per se, but based their guidelines on chronic toxicity. They caution that the guidelines that they have developed 'may not protect wildlife that consume aquatic life'. As well, they considered marine and fresh waters separately, even though there is no reason to suspect that the chemistry of each affects mercury or its bioaccumulation in fish and avian wildlife and do not provide a guideline for MeHg in marine water.

(b) The 1989 BC Environment guidelines for a maximum mercury concentration in either fresh or marine waters has been deleted due to the bioaccumulative nature of mercury which is the most important consideration in developing guidelines. Direct toxic effects that a maximum concentration is meant to protect against are seldom encountered and will be accounted for in bioaccumulation in most cases.

3. WILDLIFE

The 30-day average concentration of total mercury in water to protect wildlife should not exceed levels shown in Section 2 above. These guidelines are based on the tissue residue guideline recommended by the CCME (2000), and will protect the most sensitive avian life feeding on aquatic organisms that may accumulate undesirable levels of mercury in their tissues. This guideline replaces the 1989 BC Environment guideline of 3.0 mg THg/L that had been based on livestock sensitivity to mercury since there were insufficient data on mercury toxicity to avian wildlife. The CCME (2000) did not recommend mercury guidelines for wildlife.

Additionally, the methyl mercury concentration should not exceed 0.033 µg/g wet weight in the diet of wildlife. This guideline is consistent with the CCME (2000) tissue guidelines to protect avian wildlife feeding on fish and shellfish containing mercury.

4. LIVESTOCK WATER SUPPLY

The concentration of total mercury in livestock water supply should not exceed 3.0 µg/L at any time. This is consistent with the 1989 BC Environment and the CCME (1999) guidelines.

5. IRRIGATION

The maximum concentration of total mercury in irrigation water should not exceed 2.0 µg/L. This is consistent with the 1989 BC Environment guideline. The CCME (1999) did not recommend mercury guidelines for water used for irrigation.

Application of the Guidelines

1. FORMS OF MERCURY

Toxicity of mercury has been expressed in terms of both total and methyl forms of mercury. However, total mercury is recommended for setting water quality objectives for a given waterbody. The advantages of expressing toxicity on the basis of total mercury concentrations are:

i. all the mercury that may potentially be toxic is included in the measurement; if the total mercury concentration in water is within the guideline limits, then it is safe to conclude that no mercury pollution exists;
ii. for comparison purposes, there is a considerable amount of historical information available for total mercury; and
iii. total mercury measurements are routine and relatively inexpensive.

Mercury in aquatic organisms (e.g., fish) is predominantly in the methyl form and should also be measured when investigating mercury contamination problems in aquatic systems. The CCME recommended tissue residue guideline (0.033 micrograms MeHg/g wet weight-diet) should apply to protect wildlife consumers of fish.

The main disadvantage of using total mercury to assess water quality is that a large fraction of mercury may become biologically unavailable by forming complexes with the organic and suspended solids fractions of water. Nevertheless, given favourable environmental conditions, mercury complexed in such a manner will be released into the environment in readily available forms, becoming part of the food chain.

2. ASSESSMENT OF EXISTING WATER QUALITY

The guidelines recommended in this document are primarily based on laboratory bioassays that usually are performed with soluble forms of mercury under controlled conditions. Aquatic organisms in a natural environment, however, obtain their mercury burden from both water and food. Mercury from sediments

could become available to the organisms under certain environmental conditions. Thus measuring total mercury in water alone cannot be taken as a true measure of a mercury problem in a given waterbody.

Other assessment techniques include measurements of mercury in fish, and long-term bioassays with resident species using local water. The guidelines for mercury in fish can be used for to assess existing water quality. Long-term bioassays are complex and costly, and should be used for waterbodies with high fisheries values that are threatened by a controllable source.

The role of sulfate-reducing bacteria (SRB) in the cycling of Fe and S was studied in a young constructed wetland located in Kanata, Ontario, Canada. The wetland is a surface-flow system composed of three consecutive cells. Sediments and water samples were collected over the course of 1 year within each cell. Sediments were analyzed for the presence of SRB (using a lactate-rich medium), whereas surface and porewaters were analyzed for their concentrations of dissolved Fe and sulfate and for pH, E_h*, and dissolved organic carbon. Lactate-using SRB were present at all three sites within the wetland, and the populations were largest (*10^{10} *colony-forming units per gram of sediment) during the cold winter months, where the temperature of the water was ~1° C. The presence of high-SRB populations also corresponded to highly anoxic conditions within the sediments and to a decrease of sulfate concentrations, suggesting that cold temperature did not affect the activity of SRB. Our results indicate that Fe and S cycling in the young constructed wetland was active throughout the year, especially in the cold winter months, where large SRB populations were encountered. This suggests that Fe removal in wetlands can be effective in temperate climates, even though the temperature of the water decreases drastically during the winter.*

Keywords constructed wetland, iron cycling, sulfate-reducing bacteria, sulfur cycling

Biogeochemical reactions responsible for metal removal in constructed wetlands include adsorption onto reactive mineral and organic surfaces and precipitation as insoluble metal

Received 10 December 1999; accepted 3 April 2000.

We thank the city of Kanata, Ontario, Canada, for allowing us to sample the wetland. The project was supported by the University of Ottawa Research Fund and the Interfaculty Collaborative Research Fund. We also thank F.R. Pick and two anonymous reviewers for their constructive comments and suggestions.

oxides and sulfides (Tarutis and Unz 1996). Of all these processes, microbial sulfate reduction and the subsequent precipitation of metal sulfides have been identified as important reactions in metal removal in wetlands (Machemer and Wildeman 1992; Feng and Hsieh 1998; Webb et al. 1998). In fact, in many low-temperature sedimentary environments, microbial sulfate reduction is the sole mechanism responsible for the formation of iron monosulfides and pyrite (Berner 1984). Recent work has shown that such iron sulfide minerals play an important role in trace metal adsorption in anoxic sediments (Huerta-Diaz et al. 1998).

Microbial sulfate reduction depends on various physicochemical factors, including the supply of sulfates, the amount and type of organic electron donors, pH, and temperature (Berner 1984). In freshwater environments, such as wetlands, sulfate reduction rates are generally limited by the amount of sulfate, because the average SO_4 concentrations are ~50 to 450 μM (Feng and Hsieh 1998). In constructed wetlands, however, sulfate concentrations can be greater because of wastewater loading and anthropogenic activities. A second important factor influencing sulfate reduction in natural aqueous environments is temperature. Temperature effects on the growth of and reduction rates by sulfate-reducing bacteria (SRB) have been studied in sediments in cold climates, such as the Arctic and Antarctic (Isaksen and Jorgensen 1996; Sageman et al. 1998). The latter showed that SRB from Arctic sediments grew well at very low temperatures, but the sulfate reduction rates were greatest at much higher temperatures. The same studies concluded that sulfate reduction rates were more dependent on substrate supply than on temperature.

There is much concern about metal retention by constructed wetlands in northern climates (Maehlum et al. 1995; Reddy and Burgoon 1996). As surface water temperature decreases, microbial sulfate reduction rates are believed to decrease, perhaps leading to a decrease in metal retention. Data on the effect of temperature on SRB growth and sulfate reduction rates in wetlands are, however, limited. Batal (1989) hypothesized that SRB increase their numbers in cold water because the decrease in their metabolic rate provides more substrate for growth of other SRB. Therefore, metal retention, especially Fe, during the winter should be sustained because the increasing number of SRB should maintain the sulfate reduction rates.

The present study was initiated to examine the impact of seasonal variations of SRB populations on the cycling of Fe and SO_4 in the sediments of a young constructed wetland built to treat municipal and agricultural runoff. Seasonal variations in SRB numbers were expected to affect the removal of soluble Fe from the water.

Materials and Methods

Site Description

The Monahan wetland, located in the city of Kanata, Ontario, Canada, is a surface-flow system that was built in 1995 to control the quantity and quality of storm water runoff. The wetland is referred to as a young wetland because it has yet to accumulate a substantial amount of organic matter in its sediments. In young wetlands, the retention of metals depends more on adsorption onto organic matter than on microbial sulfate reduction observed in older wetlands (Machemer and Wildeman 1992). The Monahan wetland was designed to keep water velocities <0.5 m/s and to hold 35,000 m^3 of water. The mean water depth is 1.5 m and the total drainage basin area of the wetland is ~637 ha. The wetland itself has three consecutive cells, which were lined initially with a thick layer of clay to prevent water infiltration into the underlying aquifer. No organic substrate was added on the clay liner. The Monahan wetland is mainly colonized by cattails (*Typha latifolia*) (Table 1). Phosphorus loading to the Monahan wetland is relatively high (0.17 mg/L), which results in an intense

Sampling

Sediments and porewater samples were taken in each cell (at locations called sites 1, 2, and 3) of the wetland (Table 1). Sediments were collected in October and December 1997 and in April and August 1998. One sediment core was taken at each sampling date and site with a 10-cm-diameter plexiglass tube and was sectioned on site into 1-cm intervals. To avoid contamination, samples used for bacterial enumeration were taken in the middle of the core and stored in sterile glass vials. To minimize air contact, the vials were completely filled with sediments and stored on ice until their return to the laboratory. Most probable number (MPN) enumeration was carried out within 24 h of sampling. In situ measurements of pH and redox were also performed on the same sediment cores, using a portable pH meter. The pH electrode was calibrated on site with pH standards (at pH 4 and 7). The redox electrode was also calibrated on site with the ZoBell's solution (Nordstrom 1977). A second set of samples was taken in October 1997 for analysis of geochemical fractions. The sediments were placed in acid-washed bottles and kept at 4°C until being freeze-dried. Fresh surface sediments (from 0–2 cm deep) were also analyzed for organic matter content, as determined by loss on ignition.

Porewater samples (peepers) were collected in December 1997 and in April and August 1998 with plexiglass peepers. One peeper was installed per site and sampling date. Porewater peepers were filled with degassed ultrapure water and closed with a 0.2-μm pore-size filtering membrane (HT-Tufryn; Gelman Scientific). Peepers were inserted vertically into the sediments (not more than 0.5 m from the sediment cores) and left in place for 2 weeks (Carignan 1984). The peepers allowed for the collection of interstitial and surface waters at 1-cm-intervals along a 35-cm profile. Water samples were retrieved with 5-ml plastic syringes and transferred into preacidified plastic bottles (10 μl of conc. HCl for 4 ml of sample). Water sample collection was completed within 1 h of the retrieval of the peepers. The temperature of the overlying waters was also monitored on a monthly basis over the course of the sampling period. Surface water samples were collected every 3 days from April 1997 to October 1997 at site 1 (inflow) and site 3 (outflow). Samples were filtered (with 0.45-μm pore-size filter) and acidified after collection and analyzed for dissolved organic carbon (DOC) by using a DC-190 (Hewlett Packard) TOC analyzer.

MPN Counts of SRB

Numbers of viable SRB were estimated with MPN dilutions in liquid medium (American Public Health Association, 1965) within 24 h of sampling. A modified version of Postgate's

growth medium B (Postgate 1984; 10 g/L Bacto-Tryptone [Difco], 5.9 ml 60% Na-lactate, 2 g/L $MgSO_4 \cdot 7H_2O$, 0.5 g/L Fe $SO_4 \cdot 7H_2O$, and 0.5 g/L Na_2SO_3) was used along with a reducing agent supplement (RAS; 7.5 g/L ascorbic acid and 7.5 ml/L thioglycollic acid). All solutions were adjusted to pH 7.50 with 2 M NaOH. Dilution series (1:10) were carried out in culture tubes, starting with ~1 g of wet sample in 9 ml of reduced water (100 ml/L RAS and 2.1 g/L NaCl adjusted to pH 7.50 with 2 M NaOH). Between each dilution, the tubes were vortex-mixed for 1 min to thoroughly disperse the bacteria and sediments. Five tubes containing 9 ml of growth medium and 1 ml of RAS were then individually inoculated with 1 ml from each dilution set. Sealed tubes were left in the dark at room temperature until black Fe-sulfide precipitates started to form (~1–2 weeks). Note that the medium used might have preferentially selected lactate-utilizing SRB over nonlactate users.

Sequential Chemical Extraction

Sediments were subjected to a sequential chemical extraction to separate them into three iron-rich fractions: Fe-reactive, including oxides, carbonates, monosulfides, and hydrous aluminosilicates; Fe-silicates; and Fe-pyrite (Huerta-Diaz et al. 1993). Freeze-dried sediments (0.25 g) were first digested with 1 M HCl (10 ml) for 16 h. Iron concentration in the HCl fraction is referred to as Fe-reactive. The solid residue was then placed in 10 M HF (30 ml) for 16 h to extract Fe from silicate minerals, and finally any remaining residue was transferred to concentrated HNO_3 (10 ml) for 2 h to assess the pyrite fraction. All extractions were run on duplicate samples.

Iron and Sulfate Analysis

Sulfate concentrations in the porewater samples were analyzed by ion chromatography (Dionex DX-100) with a detection limit of 20 μM. Iron concentrations were measured by graphite furnace atomic absorption spectroscopy (Varian Spectra AA-250 plus), with a detection limit of 0.09 μM. Blanks and certified standards (SCP Science Canada) were used to ascertain the accuracy of the porewater Fe and SO_4 measurements. The iron content of each extraction fraction was analyzed by flame atomic absorption (Varian AA-1475) with use of appropriate standards and matrices; the detection limit of that method for Fe was 1.7 μM.

Statistical Analyses

Statistical analyses were performed with Systat 7.0 for Windows 95. Spatial and temporal differences in DOC content in surface water were tested by using a two-way parametric analysis of variances (ANOVA). Assumptions of the parametric ANOVA were tested with Wilkes–Shapiro test for normality of residuals, with Levene's test for homoscedasticity and with autocorrelation plots for independence among residuals.

Results

SRB Populations

Temperatures of surface water dropped near the freezing point in the winter, and a thin layer of ice (5–15 cm) developed over most of the wetland (Figure 1). Nevertheless, SRB were observed at all three sampling sites during each of the sampling periods (Figure 2), being recovered from the first 10 cm of sediment (organic and inorganic sedimentary material and clays from the liner material put at the bottom of the wetland during its construction). SRB

populations varied with depth at all sites but appeared to fluctuate most as a function of the season, especially near the sediment–water interface. In fact, the largest SRB populations were encountered at site 1 during the winter sampling in December. The smallest SRB populations were seen in the upper layer of sediments at sites 1 and 2 in April.

Surface and Porewater Chemistry

The pH of interstitial waters was between 7.00 and 8.50 (Figure 3) and remained fairly stable with respect to both depth and sampling time. A slight pH increase was observed near the sediment–water interface at site 1 in August, at site 2 in October and April, and at site 3 at all sampling dates. On the other hand, redox conditions varied greatly with depth and sampling time (Figure 3). Although anoxic conditions prevailed in the sediment deeper than 1–2 cm, slightly oxic conditions were encountered near the sediment–water interface at site 1 in April and August, whereas the sediments were anoxic in October. At site 2, suboxic conditions prevailed near the surface in October and April, whereas the surface sediments were slightly anoxic in August. At site 3, conditions were suboxic to oxic near the surface in October and April, whereas the sediments were completely anoxic in August. Samples were not analyzed for pH and E_h in December.

One set of data for iron and sulfate is missing for site 3 in December, because the peeper could not be recovered from under the ice. At all sites and sampling times, Fe was not detected in the overlying waters, except at sites 1 and 2 in December, which had low concentrations of Fe (Figure 4). For all sites, Fe concentrations increased drastically near or at the sediment–water interface, especially at site 1 in April, at site 2 in December, and at site 3 in April (Figure 4). In addition, large fluctuations were observed within the sediments, especially in the deeper portion of the profiles, where sedimentary particles were mixed with clays. Sulfate concentrations showed a very different trend: Concentrations were greatest in the overlying waters and decreased sharply in the sediments (Figure 5). Sulfate

concentrations never exceeded 300 μmol/L below the sediment–water interface and did not vary much as a function of time. On the other hand, seasonal variations were observed in the overlying waters at all sites (Figure 5). The largest SO_4 concentrations were encountered in December at sites 1 and 2, were less in April, and reached a minimum in August.

DOC concentrations in the surface waters varied on temporal and spatial scales (Table 2). DOC concentrations ranged from 5.96 to 12.04 mg/L and differed significantly between seasons (Table 3). Throughout the year, basis, DOC concentrations at the inlet were significantly lower than at the outlet. The same difference in DOC concentrations between the inlet and outlet also occurred at each sampling date. DOC concentrations were particularly high in June 97, reaching 9.50 and 12.04 mg/L at the inlet and outlet, respectively.

Sediment Chemistry

The organic matter content of the surface sediments varied slightly between the three sampling sites (Table 1), with slightly higher values at sites 2 (middle cell) and 3 (outflow) than at

site 1 (inflow). The reactive iron fraction showed a slight increase near the sediment–water interface at all three sites, whereas the silicate fraction fluctuated with depth (Figure 6). Fe concentrations associated with the pyrite fraction were less than those observed in the Fe-reactive and silicate fractions. In fact, no Fe was detected in the pyrite fraction at site 3.

Discussion

Fe and S Cycling and Redox Fluctuations

The cycling of iron and sulfur in wetlands and other aquatic environments is affected by redox reactions, which are triggered by the mineralization of organic matter (Stumm and Sulzberger 1992). In fact, the rapid consumption of oxygen during the degradation of organic matter and the subsequent use of alternate electron acceptors can move the oxic/anoxic barrier toward the sediment–water interface and create anoxic conditions in the surficial sediments (Froelich et al. 1979). Such redox fluctuations were observed in the sediments of the Monahan wetland throughout the year, especially in the top 2 cm of the sediments (Figure 3), in which completely anoxic conditions were encountered in October at site 1 and in August at site 3. Redox measurements were not made in December, but the presence of reducing conditions in the surface sediments and in the overlying waters of sites 1 and 2 was inferred by the presence of soluble Fe above the sediment–water interface (Figure 4). Under reducing conditions, Fe-rich minerals such as Fe-oxides undergo reductive dissolution,

which allows Fe(II) to either diffuse upward into the overlying waters or downward into the sediments (Stumm and Sulzberger 1992). The presence of an ice cover over most of the wetland during the winter months might have also contributed to the presence of anoxic conditions by limiting oxygen diffusion into the water. Redox fluctuations, however, were not constant within the wetland. For example, site 3 (outflow) often behaved differently from site 1 (inflow), and surface sediments near the inflow tended to be less oxic overall than the sediments at sites 2 and 3, even though they contained less organic material in the sediments and in the water at site 1 (Tables 1 and 2). These cell differences were probably caused by various degrees of oxygen consumption and differences in microbial activity throughout the year.

Sulfate concentration profiles in the Monahan wetland indicate that sulfate was reduced near the sediment–water interface (Figure 5), as indicated by the sharp decrease of concentrations in the sediments. Sulfate reduction was observed over the course of the year and did not appear to be limited to warmer months. In fact, sulfate concentrations within the sediments remained constant, whereas concentrations in the overlying waters increased during the winter months—probably because of the use of de-icing agents containing sulfate salts or sulfate impurities on the surrounding roads (Shanley 1994).

Microbial Sulfate Reduction

The decrease of sulfate concentrations showed a positive correlation with the presence of SRB in the sediments (Figures 2 and 5). SRB were indeed recovered throughout the year and did not appear to be greatly affected by the presence of suboxic conditions in the surface sediments or by the temperature. SRB were generally present in the surface sediments where oxic conditions prevailed, except at sites 1 and 2 in April 1998, where they were absent (Figure 2). This suggests that SRB were either oxygen-tolerant or living in anoxic microenvironments within the oxic sediments. Oxygen usually inhibits microbial sulfate reduction (Widdel 1988), but sulfate reducers have been isolated from oxic to suboxic environments (Canfield and DesMarais 1991; Sass et al. 1997). Visual observation of the wetland surface sediments revealed the presence of small black patches rich in Fe-sulfides within the oxic sediments, indicating the presence of microenvironments. On the other hand, the absence of SRB in the surface sediments at sites 1 and 2 in April and their presence at site 3 suggest possible changes in population dynamics.

Our results also indicate that SRB thrived during the colder months. In fact, the largest populations were encountered in December, when the temperature of the water was ~1°C (Figure 2). The largest SRB populations also corresponded to the largest decline of sulfate concentrations (Figure 5), suggesting an apparent increase in sulfate reduction during the colder months. Our results are surprising, because sulfate reduction rates in natural aquatic environments usually decrease during colder months (Abdollahi and Nedwell 1979; Moeslund et al. 1994; Holmer and Kristensen 1996). However, recent work by Sageman et al. (1998) and Isaksen and Jorgensen (1996) showed that optimum growth temperature for SRB isolated from cold environments was often higher than the in situ temperature, but the sulfate reduction rates were comparable with those measured in sediments of temperate climates. Numerous studies have also suggested that cold temperature might not inhibit bacterial life but might diminish the affinity of the bacteria for substrates (Wiebe et al. 1992; Nedwell and Rutter 1994; Isaksen and Jorgensen 1996; Sageman et al. 1998). It is difficult to conclude from our results that substrate affinity was a key factor in SRB growth at cold temperature, because we did not identify the various types of SRB and organic substrates in the water. In fact, it is possible that the growth medium used for the enumeration (MPN) preferentially selected lactate-utilizing SRB, which might not be representative of the whole SRB population in the wetland. Regarding substrate availability,

our limited number of DOC values (Table 2) suggest that the pool of organic substrates varied throughout the year from one site to the other, being generally lower in the winter because of low primary productivity (Mann and Wetzel 1995). Our results indicate that to compensate for the low organic content of the sediments and the potential lower affinity for the substrates, SRB increased in number during the colder months, which had the effect of maintaining the sulfate reduction rates throughout the year. Clearly more work is needed on the characterization and availability of potential organic donors to assess the role of substrate affinity.

SRB and Fe-Rich Mineral Formation

The dynamics of SRB populations and their effect on sulfur and iron cycling affected the mineralogy of the wetland sediments. The constructed wetland was 2 years old at the time of sampling and originally contained clay material at the bottom. Results from the chemical extraction (Figure 6) indicated that the surface sediments were enriched in reactive Fe, indicating that Fe was bound to carbonates, oxides, monosulfides, and hydrous aluminosilicates (Huerta-Diaz et al. 1993). In most natural aquatic environments, the enrichment of Fe-reactive compounds corresponds to the formation of diagenetic Fe-oxides and Fe-monosulfides (FeS). Diagenetic Fe-oxides usually form when soluble Fe(II) from anoxic sediments diffuses upward toward the oxic–anoxic interface and is oxidized to Fe(III) (Fortin et al. 1993), whereas Fe-monosulfides precipitate as a result of sulfide production during microbial sulfate reduction (Berner 1984). Seasonal variations in Fe and S cycling are therefore responsible for the enrichment in reactive Fe in the constructed wetland. On the other hand, the Fe-silicate fraction showed no distinctive patterns but simply reflected the existence of the clay material emplaced during construction of the wetland and its redistribution through bioturbation. In fact, visual observation of the sediment cores indicated that the clay material in the deeper portion of the core was often mixed with black precipitates, probably Fe-sulfides. Our results also showed that pyrite (FeS_2) formed within the wetland, but only at sites 1 and 2. Pyrite formation is not a direct by-product of microbial sulfate reduction; its formation in aquatic environments is often attributed to the reaction of Fe-monosulfides with dissolved sulfides (Berner 1984; Schoonen and Barnes 1991; Donald and Southam 1999). Our results indicate that the formation of pyrite might have been inhibited in the outflow basin (site 3), perhaps because of a low production of sulfides. However, SRB populations in October were at their greatest, which suggests a large supply of dissolved sulfides (Figure 2). Clearly, the presence of SRB alone cannot explain the absence of pyrite at site 3; the solubility of pyrite is also a function of physicochemical factors, such as the presence of sulfide-complexing agents and the concentration on Fe (Howarth et al. 1983; Howarth and Merkel 1984). In fact, our results indicate that the concentrations of dissolved Fe in the anoxic sediments of site 3 were 3 to 8 times lower than the ones at sites 1 and 2, respectively (Figure 4).

In conclusion, Fe and S cycling in the young Monahan constructed wetland was active throughout the year, especially in the cold winter months, where large SRB populations were encountered. This suggests that metal removal in young wetlands, especially Fe, is effective in temperate climates, even when the temperature of the waters decreases drastically in the winter.

Attention: Aaron MacDonell
Director of Environmental Services
Kinross Gold Corp.

Dear Aaron MacDonell,

RE: Great Bear Project Mercury Study Plan

On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows"), we write in response to the Mercury Study Plan (the "Study Plan") prepared by WSP Canada Inc. on behalf of Great Bear Resources, as per the requirement in the Tailored Impact Statement Guidelines ("TISG") issued by the Impact Assessment Agency of Canada (the "Agency" or "IAAC") for the Great Bear Gold Project (the "Project") on August 1, 2024.

The TISG requires the proponent to "submit a study plan to the Agency with sufficient time to facilitate a review by experts and interested parties and to inform the studies undertaken." With respect to the study plan, the IAAC notes in the TISG that "the potential for project contributions to methylmercury production in downstream watersheds requires a detailed and robust analysis" that includes "establishing baseline methodology and effects assessment methodology related to methylmercury." (emphasis added)

Our experts have previously raised significant concerns with respect to the quality and quantity of baseline data and monitoring completed to date, and the monitoring planned, with respect to the Great Bear Gold Project. These concerns remain. The Study Plan does not provide us with adequate assurance that this preliminary work will be accurately and adequately completed before the proponent moves forward with the necessary studies and engages in risky Advanced Exploration ("AEX") construction and mining activities. Any studies completed based on erroneous and unreliable data will not provide Grassy Narrows with the necessary information we need to properly assess the potential impacts of the Project on our inherent, Aboriginal, and Treaty rights, nor will it provide the External Technical Reviewers ("ETR") with the technically rigorous and accurate information that they need to assess the impacts of mercury and methylation during the Impact Assessment process.

Our experts are also concerned with the effects assessment methodology proposed, including the use of inadequate baseline data, unclear monitoring, flawed ML-ARD work, and unsuitable modelling software.

The proposed software has technical limitations that will prevent it from being successfully applied in the manner proposed to address the biogeochemical aspects of mercury methylation across the landscape and methylmercury uptake by biota. The Study Plan indicates that the software will not be modeled downstream of the Project site and important details, such as a

mixing zone in between “nodes”, cannot be simulated in sufficient detail. As well, the model does not intend to assess cumulative impacts and methylation potential at the discharge point, downstream and throughout the broader river system.

The Study Plan thus presents a model that is unable to predict mercury biogeochemical processes, and which is dependent on background data and proposed monitoring that is insufficient. As we address below, any study based on this Plan is bound to fail and will be inadequate for its intended purposes as outlined in the TISG.

Request for extension to provide comments

The IAAC directed the proponent to submit a study plan with “sufficient time to facilitate a review by experts and interested parties.” (emphasis added) A few weeks is not enough time for Grassy Narrows to complete the necessary review, particularly because a significant portion of the review period extended over the Christmas holidays. The holidays are one of the only times when Grassy Narrows people are usually able to lower the level of stress and anxiety that the mercury crisis and industrial threats have brought to the community. Establishing short comment periods for critical plans related to toxic threats over the holidays exacerbates the stress and anxiety which have fueled a well-documented mental health and suicide crisis in Grassy Narrows. This is a concern that Grassy Narrows has explained repeatedly to Kinross and to the IAAC. The fact that this grave concern is being ignored is emblematic of the unilateral, coercive, reckless, and disrespectful nature of this Project and this process to date. The timeline provided by Great Bear is insufficient to review the proposed Study Plan, to engage with our experts and our community in a fulsome manner, to carry out our governance process, and to develop a fulsome response.

While you insist that you will not pause your work on the Impact Assessment as you must adhere to the Impact Assessment timelines, the IAAC continues to tell us that this is not the case. The IAAC informs us that the proponent can agree to a pause in the Impact Assessment process at any time. As well, the IAAC has assured us that there is no deadline by which the proponent is required to submit the Study Plan. In fact, IAAC agreed that it would be proper for the ETR to have the opportunity to review the Study Plan and provide input prior to proceeded with the studies. The ETR Terms of Reference have yet to be set, the selection process has yet to be finalized, and its membership has yet to be selected. It is premature to close the comment period on the Study Plan.

It is in everyone’s interest for Grassy Narrows and our external experts to have enough time to review the Study Plan prior to proceeding with the study/studies to ensure that the studies are “detailed and robust”, the ETR has the information they need to adequately assess methylation-related issues, and the Impact Assessment is completed in a technically rigorous manner. If the study proceeds without sufficient time for effective peer review, or with a flawed methodology, then its results will not be reliable. It is not prudent nor rational to proceed with the Study Plan in these circumstances. We reiterate our request for an extension to provide fulsome comments.

Preliminary comments

We have been unable to complete a fulsome review of this critical document which will inform the proponent’s analysis of methylmercury, a key concern identified by Grassy Narrows during the Planning Phase of the federal Impact Assessment and throughout other regulatory review processes. However, as you insist that you will move forward with the studies without us, we are submitting our preliminary comments.

We have also enclosed two initial reports from our experts who have completed a preliminary technical review of the Study Plan to date: (1) Preliminary Report by Dr. Brian Branfireun, and (2) Preliminary Report by Dr. Kevin Morin. Note that Dr. Branfireun is an internationally recognized expert in the field of watershed biogeochemistry and the environmental cycling of mercury, including methylation, and his insights with respect to the methodologies proposed are particularly valuable.

Grassy Narrows' previous submissions should also be meaningfully integrated into a revised Study Plan, including our initial March 2024 submissions and subsequent submissions from Grassy Narrows and our experts in response to the PTTW, ECA for ISW, and Closure Plan applications. These submissions include important content that relates to the Study Plan, including information about Grassy Narrows' concerns and priorities; the sufficiency of generic guidelines for the protection of aquatic wildlife; deficiencies in the components of the planned study, including with respect to baseline data, monitoring plans, ML-ARD, groundwater modelling, and mitigation plans, among other things; and deficiencies in the review process to date.

1. **The proponent's reliance on achieving on/off site water quality that complies with PWQO and CCME water quality guidelines is inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota.**

The Plan states that to date, water quality monitoring shows that mercury and methylmercury concentrations in water are below Canadian Council of Ministers of the Environment ("CCME") water quality guidelines for the protection of aquatic life. It is clear that the proponent intends to apply CCME guidelines to the Project as "comparisons", but also as regulatory thresholds from a compliance standpoint.

Dr. Branfireun continues to opine that CCME guidelines for mercury and methylmercury are "useless for the protection of fish consumers, and even if discharges or indirect effects were a fraction of these guideline limits there would be significant potential for downstream impairments of aquatic resources." The CCME guidelines for total mercury and methylmercury for the protection of aquatic life are significantly above background levels. For example, the CCME guideline for total mercury in surface water is roughly 10-20-fold higher than uncontaminated baseline levels of mercury in the English River watershed. Previous submissions by Dr. Branfireun are clear that any increase in mercury above baseline in water would be expected to be reflected in walleye.

The CCME document itself provides that it "does not address exposure through food or bioaccumulation to higher trophic levels" and that "if the ultimate management objective for mercury is to protect high trophic level aquatic life and/or those wildlife that prey on aquatic life, more stringent site-specific application of these water quality guidelines may be necessary." Stringent site-specific guidelines are necessary in the circumstances. These site-specific guidelines must take into account the specific ecosystem, watershed, bioaccumulation, subsistence human consumers of high trophic level fish and wildlife, cumulative impacts, and the ongoing mercury crisis in Grassy Narrows. Grassy Narrows has raised this issue consistently since its first submission on the Great Bear Gold Project, and we have yet to see it reflected in the project plans including this Mercury Study Plan. The information that Grassy Narrows and its experts have provided about mercury and methylation continues to be ignored.

It is unclear what guideline levels, if any, are being proposed for sulphate, and for other parameters that impact methylation including DOC, temperature, light penetration, and pH, among others. However, the sulphate guideline levels for the receiving environment proposed in the ECA application were found by Dr. Branfireun to be entirely inappropriate for the purpose of preventing methylation impacts. If Kinross is planning to use those same levels here, then the results of this study will be erroneous.

The Study Plan must establish site specific criterion for mercury, methylmercury, sulphate, and other parameters that impact methylation, based on appropriate baseline data, and the site-specific factors noted above, not based on generic national standards that have not been designed for bioaccumulation nor for subsistence fish eaters and/or previously exposed populations. Methodology that relies on "useless" comparators and guidelines will not lead to an analysis that is "detailed and robust."

2. **The background data collected as part of the baseline studies for this Project are largely erroneous or their interpretation is flawed, which makes them insufficient to detect whether the project will have a measurable impact on fish mercury levels in the future.**

Grassy Narrows continues to raise concerns with respect to the background data collected by the proponent as part of their baseline studies. The proponent has not corrected many of the baseline study problems identified by Grassy Narrows' experts. Serious data quality problems remain and any methodology that proposes modelling based on such erroneous data will lead to study results that are inaccurate and ineffective, rendering the entire study useless, and posing serious risks to Grassy Narrows.

Dr. Branfireun continues to opine that "in the context of the protection of fish consumers, nearly all of the background data for total mercury are useless and stated incorrectly." The background mercury data in water is incorrect. The data provided for mercury are not data but are instead detection limits of the contract laboratory. The detection limits for methylmercury are higher than background levels in the English River. Concentrations reported for sulphate have also been erroneous up until May 2023 when the proponent appears to have changed analytical methods or laboratories which was not documented, contrary to best practices.

The baseline studies and proposed methodology with respect to biota are similarly inadequate. The proponent has not collected consistent species to allow for comparison between years, assessed both high trophic sport fish and low trophic indicator species, nor identified the frequency and duration of any studies.

The Study Plan relies on background data about mercury and sulphate that will inform modelling efforts and trigger undefined actions should they change. Dr. Branfireun opines that the proponent proposes to use an "inappropriate analytical approach" that will "reliably generate non-data that will not capture trends in mercury concentrations across most of the sampling sites in the project area."

The baseline studies have a number of other key deficiencies including:

1) The baseline studies are being conducted after activities that can impact methylation (such as road and machine track construction, forest clearing, drilling, soil impacts, and other industrial activities) have already occurred. This makes it impossible for most sampling sites to establish a baseline that is free of project impacts or those from other

projects.

2) Further activities that can impact methylation are planned to be carried out over the study period including extensive Advanced Exploration activity that includes activities normally considered to be mine construction. This will further interfere with the ability to establish a proper baseline.

3) There are no baseline sites in the Chukuni River that are upstream of the potential impacts of other mine sites including the Red Lake Mine and the Madsen Mine. Therefore, the baseline will likely reflect contaminated conditions which will obscure impacts from this project.

4) There are no baseline sites downstream of Pakwash Lake even though dissolved methylmercury and sulphate can travel long distances downstream and have impacts large distances from the discharge point.

5) The Plan is lacking detail so the precise sampling purpose, locations, protocols, and durations cannot be evaluated.

Grassy Narrows has repeatedly expressed a lack of trust that a profit motivated gold mining company, nor its partners, can be relied upon to establish a credible baseline. The highly critical expert reviews of the baseline work to date and the monitoring plans further substantiate Grassy Narrows' concerns. Grassy Narrows has repeatedly requested that the Crown or the proponent support Grassy Narrows to carry out a credible baseline study. However, neither the Crown nor Kinross have supported this work to date. The result is that the baseline work and plans to date are fundamentally flawed and incapable of effectively supporting risk assessment and mitigation.

Well-designed baseline studies are required to be carried out over a number of years in order to establish a baseline with a reasonable level of confidence in the range of natural variation in the baseline. Without this, it will be impossible to know whether changes seen during monitoring are due to the project or due to natural variation.

3. **Metal Leaching and Acid Rock Drainage prediction methods are improper.**

Another key input into the Study Plan is the prediction of which substances will be generated by the overburden, ore, and tailings from the project and their concentrations (ML-ARD). Previous submissions by Source Environmental note that the project has yet to complete a credible contaminants of concern assessment.

Dr. Morin similarly explains that the proponent continues to use the same ML-ARD approach and testing as Advanced Exploration and fails to follow guidance in the federal Prediction Manual of best practice and industry standards which are required under Ontario regulations. Where the proponent has committed to conducting certain tests, such as the tests for geochemical characterization, the proponent has not released most of its results.

As well, the proponent plans to use incorrect analytical methods in the proposed studies which are flawed and "will underestimate the amount of mercury in Great Bear mined materials including the walls of underground workings and pits, waste rock, overburden, soil, and tailings." Dr. Morin opines that the proposed methods are "not appropriate, reliable, and safe for the Mercury Study." He adds that the proposed groundwater modelling is similarly unreliable. Dr.

Morin concludes that he expects that the proponent will underestimate the important geochemical input and groundwater flow leaving its Gear Bear site which is “critical for a reliable outcome from the proposed Mercury Study.”

The proponent should not proceed with the Study Plan until there is high quality ML-ARD data and baseline data over multiple years for the model, and a credible monitoring plan in place. This must also be completed before the proponent proceeds with further activities that could cause potential impacts, including impacts to baseline data, for example, AEX construction, road and trail building, etc.

4. **The assimilative capacity of the receiving waters as a mitigation strategy for excess sulphate loading is not supported by the available data.**

The proponent continues to present a mitigation strategy that involves “discharging treated effluent to a large receiving watercourse (Chukuni River) that has a high oxygenation level and high assimilative capacity.” Our experts have commented on this “strategy” in previous submissions, explaining that this presents an erroneous understanding of methylation in aquatic environments. Dr. Branfireun responds in detail in his enclosed report. Dr. Branfireun concludes that:

- The strategies for treating effluent to be discharged to the Chukuni River do not target sulphate, and sulphate production from overburden and waste rock are likely to be greater than the proponent states.

- The proponent’s assessment of the watercourse’s assimilative capacity is inadequate as the proponent uses the average of entire daily discharge records for all of their dilution scenarios. There are potentially dire sulphate concentrations/volumes that could arise as a result of low flows combined with higher than stated effluent sulphate concentrations/volumes.

- The proponent relies on the high oxygenation level of the Chukuni River and does not consider the methylation potential of downstream waters, nor riparian areas and porewater, where this well-oxygenated river will deliver sulphate that may be many times in excess of background levels, in particular, to downstream mercury-sensitive lakes with high mercury methylation potential.

As with other components of this project, the cumulative impacts of this project in the context of other past, present, and planned projects does not appear to have been considered. There are at least five other gold mining projects proposed or operating in this watershed, as well as a pulp mill, sawmill, dams, diversions, clearcut logging, and municipal waste.

As well, the other mitigation measures described in the Study Plan are generally vague, unclear, and incomplete, and the list of potential effects is similarly incomplete and does not include potential effects from road and trail construction, site clearing, soil impacts, and water/dewatering, for example. There is insufficient information available for Grassy Narrows to adequately assess the proposed mitigation measures, and the information provided to date does not satisfy our experts that the proposed measures are effective and safe.

5. **The proposed model that the proponent plans to use to predict changes in sulphate, mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish cannot technically**

deliver on those outcomes.

The Study Plan states that the proponent will rely on the GoldSim software modelling package to "simulate the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project." Our experts raise significant concerns with the GoldSim software, including its inability to be applied to an environmental mercury speciation scenario, and opine that additional information on the model is required before it can be assessed as an adequate model for the methylation studies.

Dr. Morin explains that mercury and sulphate predictions will only be generated at "nodes", the areas where the user-defined "conceptual boxes" connect. This means that the predictions will not simulate waterbodies in their environmental complexity, but simply represent the internal conditions that the proponent "chooses to assume, estimate, and simulate." It is particularly concerning that the Chukuni River will only be modeled at two "nodes", immediately above and below the property boundary. There are no "nodes" in Pakwash Lake nor further downstream where there are concerns of mercury methylation. There are also no nodes at a baseline site that is upstream from the impact of other local mines and therefore reflects uncontaminated conditions. Dr. Morin explains that "because of this "node" approach, important details like an initial dilution zone (a mixing zone) in the Chukuni River between Nodes CHK-1 and CHK-2 cannot be simulated in sufficient detail."

Dr. Branfireun explains that GoldSim "does not appear to ever have been applied to an environmental mercury speciation scenario" and attributes this to the software's model which "cannot incorporate mechanistic sorption/desorption reactions along flow paths, the biomethylation process, nor the complex interaction between mercury and sulphate." Dr. Branfireun concludes that, as a result, "the model proposed can never be successfully applied in the manner that is proposed. […] A mass balance model *cannot* by definition incorporate mechanistically the input and removal processes for mercury, and *cannot* address the biogeochemical aspects of mercury methylation across the landscape which are at the root of the potential impacts associated with the Great Bear proposal."

The Study Plan, and its model, also appear to ignore a number of parameters beyond THg, meHg, and sulphate which can impact methylation dynamics including DOC, light penetration, temperature, pH, and other parameters.

We are not satisfied that the GoldSim software proposed is appropriate or technically able to apply to the circumstances and produce a useful prediction. We are concerned that the technical limitations of the software, as well as the manner in which the proponent intends to use the software, will not produce reliable, accurate, or useful predictions. Our concerns are heightened given the ongoing data quality problems in relation to the Great Bear Project – flawed data will lead to flawed results, regardless of the software chosen.

<u>Conclusion</u>

Dr. Branfireun concludes in his report:

> "We have a water quality model that is not capable of predicting mercury biogeochemical processes, that is dependent on background data and proposed monitoring that is insufficient. The outcome will be the inevitable future conclusion by the Proponent that the combination has led to an inability to adequately predict changes in methylmercury concentrations in fish because of 'uncertainties' in GoldSim output, and "unforeseen

> complexities" in coupling abiotic and biotic compartments. The reality is that these uncertainties and complexities are completely foreseeable as outlined here. […] I conclude that the TISG's requirement that the Proponent provide *a detailed and robust analysis on the potential for project contributions to methylmercury production in downstream watersheds* has not been met based on the information provided in the Mercury Plan."

In light of our experts' opinions, we are concerned with this Study Plan and require additional time to complete a fulsome review and engage with our experts in a more in depth manner, and to engage with our other experts and our community.

We reiterate our request for a 90-day extension to provide comments. It is not prudent nor rational to proceed with a Mercury Study which is built on erroneous, incomplete, and inaccurate data and which uses flawed methodology that is unable to adequately address the biogeochemical aspects of mercury methylation across the landscape as required.

We expect that the proponent will not move forward with this Study Plan, the proposed studies, or any additional work on the site that may cause adverse effects prior to receiving and meaningfully integrating our comments.

BY EMAIL

Attention: Aaron MacDonell
Director of Environmental Services
Kinross Gold Corp.

Dear Aaron MacDonell,

RE: Great Bear Project Mercury Study Plan

On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows"), we write in response to the Mercury Study Plan (the "Study Plan") prepared by WSP Canada Inc. on behalf of Great Bear Resources, as per the requirement in the Tailored Impact Statement Guidelines ("TISG") issued by the Impact Assessment Agency of Canada (the "Agency" or "IAAC") for the Great Bear Gold Project (the "Project") on August 1, 2024.

The TISG requires the proponent to "submit a study plan to the Agency with sufficient time to facilitate a review by experts and interested parties and to inform the studies undertaken." With respect to the study plan, the IAAC notes in the TISG that "the potential for project contributions to methylmercury production in downstream watersheds requires a detailed and robust analysis" that includes "establishing baseline methodology and effects assessment methodology related to methylmercury." (emphasis added)

Our experts have previously raised significant concerns with respect to the quality and quantity of baseline data and monitoring completed to date, and the monitoring planned, with respect to the Great Bear Gold Project. These concerns remain. The Study Plan does not provide us with adequate assurance that this preliminary work will be accurately and adequately completed before the proponent moves forward with the necessary studies and engages in risky Advanced Exploration ("AEX") construction and mining activities. Any studies completed based on erroneous and unreliable data will not provide Grassy Narrows with the necessary information we need to properly assess the potential impacts of the Project on our inherent, Aboriginal, and Treaty rights, nor will it provide the External Technical Reviewers ("ETR") with the technically rigorous and accurate information that they need to assess the impacts of mercury and methylation during the Impact Assessment process.

Our experts are also concerned with the effects assessment methodology proposed, including the use of inadequate baseline data, unclear monitoring, flawed ML-ARD work, and unsuitable modelling software.

The proposed software has technical limitations that will prevent it from being successfully applied in the manner proposed to address the biogeochemical aspects of mercury methylation across the landscape and methylmercury uptake by biota. The Study Plan indicates that the software will not be modeled downstream of the Project site and important details, such as a

mixing zone in between “nodes”, cannot be simulated in sufficient detail. As well, the model does not intend to assess cumulative impacts and methylation potential at the discharge point, downstream and throughout the broader river system.

The Study Plan thus presents a model that is unable to predict mercury biogeochemical processes, and which is dependent on background data and proposed monitoring that is insufficient. As we address below, any study based on this Plan is bound to fail and will be inadequate for its intended purposes as outlined in the TISG.

Request for extension to provide comments

The IAAC directed the proponent to submit a study plan with “sufficient time to facilitate a review by experts and interested parties.” (emphasis added) A few weeks is not enough time for Grassy Narrows to complete the necessary review, particularly because a significant portion of the review period extended over the Christmas holidays. The holidays are one of the only times when Grassy Narrows people are usually able to lower the level of stress and anxiety that the mercury crisis and industrial threats have brought to the community. Establishing short comment periods for critical plans related to toxic threats over the holidays exacerbates the stress and anxiety which have fueled a well-documented mental health and suicide crisis in Grassy Narrows. This is a concern that Grassy Narrows has explained repeatedly to Kinross and to the IAAC. The fact that this grave concern is being ignored is emblematic of the unilateral, coercive, reckless, and disrespectful nature of this Project and this process to date. The timeline provided by Great Bear is insufficient to review the proposed Study Plan, to engage with our experts and our community in a fulsome manner, to carry out our governance process, and to develop a fulsome response.

While you insist that you will not pause your work on the Impact Assessment as you must adhere to the Impact Assessment timelines, the IAAC continues to tell us that this is not the case. The IAAC informs us that the proponent can agree to a pause in the Impact Assessment process at any time. As well, the IAAC has assured us that there is no deadline by which the proponent is required to submit the Study Plan. In fact, IAAC agreed that it would be proper for the ETR to have the opportunity to review the Study Plan and provide input prior to proceeded with the studies. The ETR Terms of Reference have yet to be set, the selection process has yet to be finalized, and its membership has yet to be selected. It is premature to close the comment period on the Study Plan.

It is in everyone’s interest for Grassy Narrows and our external experts to have enough time to review the Study Plan prior to proceeding with the study/studies to ensure that the studies are “detailed and robust”, the ETR has the information they need to adequately assess methylation-related issues, and the Impact Assessment is completed in a technically rigorous manner. If the study proceeds without sufficient time for effective peer review, or with a flawed methodology, then its results will not be reliable. It is not prudent nor rational to proceed with the Study Plan in these circumstances. We reiterate our request for an extension to provide fulsome comments.

Preliminary comments

We have been unable to complete a fulsome review of this critical document which will inform the proponent’s analysis of methylmercury, a key concern identified by Grassy Narrows during the Planning Phase of the federal Impact Assessment and throughout other regulatory review processes. However, as you insist that you will move forward with the studies without us, we are submitting our preliminary comments.

We have also enclosed two initial reports from our experts who have completed a preliminary technical review of the Study Plan to date: (1) Preliminary Report by Dr. Brian Branfireun, and (2) Preliminary Report by Dr. Kevin Morin. Note that Dr. Branfireun is an internationally recognized expert in the field of watershed biogeochemistry and the environmental cycling of mercury, including methylation, and his insights with respect to the methodologies proposed are particularly valuable.

Grassy Narrows' previous submissions should also be meaningfully integrated into a revised Study Plan, including our initial March 2024 submissions and subsequent submissions from Grassy Narrows and our experts in response to the PTTW, ECA for ISW, and Closure Plan applications. These submissions include important content that relates to the Study Plan, including information about Grassy Narrows' concerns and priorities; the sufficiency of generic guidelines for the protection of aquatic wildlife; deficiencies in the components of the planned study, including with respect to baseline data, monitoring plans, ML-ARD, groundwater modelling, and mitigation plans, among other things; and deficiencies in the review process to date.

1. **The proponent's reliance on achieving on/off site water quality that complies with PWQO and CCME water quality guidelines is inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota.**

The Plan states that to date, water quality monitoring shows that mercury and methylmercury concentrations in water are below Canadian Council of Ministers of the Environment ("CCME") water quality guidelines for the protection of aquatic life. It is clear that the proponent intends to apply CCME guidelines to the Project as "comparisons", but also as regulatory thresholds from a compliance standpoint.

Dr. Branfireun continues to opine that CCME guidelines for mercury and methylmercury are "useless for the protection of fish consumers, and even if discharges or indirect effects were a fraction of these guideline limits there would be significant potential for downstream impairments of aquatic resources." The CCME guidelines for total mercury and methylmercury for the protection of aquatic life are significantly above background levels. For example, the CCME guideline for total mercury in surface water is roughly 10-20-fold higher than uncontaminated baseline levels of mercury in the English River watershed. Previous submissions by Dr. Branfireun are clear that any increase in mercury above baseline in water would be expected to be reflected in walleye.

The CCME document itself provides that it "does not address exposure through food or bioaccumulation to higher trophic levels" and that "if the ultimate management objective for mercury is to protect high trophic level aquatic life and/or those wildlife that prey on aquatic life, more stringent site-specific application of these water quality guidelines may be necessary." Stringent site-specific guidelines are necessary in the circumstances. These site-specific guidelines must take into account the specific ecosystem, watershed, bioaccumulation, subsistence human consumers of high trophic level fish and wildlife, cumulative impacts, and the ongoing mercury crisis in Grassy Narrows. Grassy Narrows has raised this issue consistently since its first submission on the Great Bear Gold Project, and we have yet to see it reflected in the project plans including this Mercury Study Plan. The information that Grassy Narrows and its experts have provided about mercury and methylation continues to be ignored.

It is unclear what guideline levels, if any, are being proposed for sulphate, and for other parameters that impact methylation including DOC, temperature, light penetration, and pH, among others. However, the sulphate guideline levels for the receiving environment proposed in the ECA application were found by Dr. Branfireun to be entirely inappropriate for the purpose of preventing methylation impacts. If Kinross is planning to use those same levels here, then the results of this study will be erroneous.

The Study Plan must establish site specific criterion for mercury, methylmercury, sulphate, and other parameters that impact methylation, based on appropriate baseline data, and the site-specific factors noted above, not based on generic national standards that have not been designed for bioaccumulation nor for subsistence fish eaters and/or previously exposed populations. Methodology that relies on "useless" comparators and guidelines will not lead to an analysis that is "detailed and robust."

2. **The background data collected as part of the baseline studies for this Project are largely erroneous or their interpretation is flawed, which makes them insufficient to detect whether the project will have a measurable impact on fish mercury levels in the future.**

Grassy Narrows continues to raise concerns with respect to the background data collected by the proponent as part of their baseline studies. The proponent has not corrected many of the baseline study problems identified by Grassy Narrows' experts. Serious data quality problems remain and any methodology that proposes modelling based on such erroneous data will lead to study results that are inaccurate and ineffective, rendering the entire study useless, and posing serious risks to Grassy Narrows.

Dr. Branfireun continues to opine that "in the context of the protection of fish consumers, nearly all of the background data for total mercury are useless and stated incorrectly." The background mercury data in water is incorrect. The data provided for mercury are not data but are instead detection limits of the contract laboratory. The detection limits for methylmercury are higher than background levels in the English River. Concentrations reported for sulphate have also been erroneous up until May 2023 when the proponent appears to have changed analytical methods or laboratories which was not documented, contrary to best practices.

The baseline studies and proposed methodology with respect to biota are similarly inadequate. The proponent has not collected consistent species to allow for comparison between years, assessed both high trophic sport fish and low trophic indicator species, nor identified the frequency and duration of any studies.

The Study Plan relies on background data about mercury and sulphate that will inform modelling efforts and trigger undefined actions should they change. Dr. Branfireun opines that the proponent proposes to use an "inappropriate analytical approach" that will "reliably generate non-data that will not capture trends in mercury concentrations across most of the sampling sites in the project area."

The baseline studies have a number of other key deficiencies including:

1) The baseline studies are being conducted after activities that can impact methylation (such as road and machine track construction, forest clearing, drilling, soil impacts, and other industrial activities) have already occurred. This makes it impossible for most sampling sites to establish a baseline that is free of project impacts or those from other

projects.

2) Further activities that can impact methylation are planned to be carried out over the study period including extensive Advanced Exploration activity that includes activities normally considered to be mine construction. This will further interfere with the ability to establish a proper baseline.

3) There are no baseline sites in the Chukuni River that are upstream of the potential impacts of other mine sites including the Red Lake Mine and the Madsen Mine. Therefore, the baseline will likely reflect contaminated conditions which will obscure impacts from this project.

4) There are no baseline sites downstream of Pakwash Lake even though dissolved methylmercury and sulphate can travel long distances downstream and have impacts large distances from the discharge point.

5) The Plan is lacking detail so the precise sampling purpose, locations, protocols, and durations cannot be evaluated.

Grassy Narrows has repeatedly expressed a lack of trust that a profit motivated gold mining company, nor its partners, can be relied upon to establish a credible baseline. The highly critical expert reviews of the baseline work to date and the monitoring plans further substantiate Grassy Narrows' concerns. Grassy Narrows has repeatedly requested that the Crown or the proponent support Grassy Narrows to carry out a credible baseline study. However, neither the Crown nor Kinross have supported this work to date. The result is that the baseline work and plans to date are fundamentally flawed and incapable of effectively supporting risk assessment and mitigation.

Well-designed baseline studies are required to be carried out over a number of years in order to establish a baseline with a reasonable level of confidence in the range of natural variation in the baseline. Without this, it will be impossible to know whether changes seen during monitoring are due to the project or due to natural variation.

3. **Metal Leaching and Acid Rock Drainage prediction methods are improper.**

Another key input into the Study Plan is the prediction of which substances will be generated by the overburden, ore, and tailings from the project and their concentrations (ML-ARD). Previous submissions by Source Environmental note that the project has yet to complete a credible contaminants of concern assessment.

Dr. Morin similarly explains that the proponent continues to use the same ML-ARD approach and testing as Advanced Exploration and fails to follow guidance in the federal Prediction Manual of best practice and industry standards which are required under Ontario regulations. Where the proponent has committed to conducting certain tests, such as the tests for geochemical characterization, the proponent has not released most of its results.

As well, the proponent plans to use incorrect analytical methods in the proposed studies which are flawed and "will underestimate the amount of mercury in Great Bear mined materials including the walls of underground workings and pits, waste rock, overburden, soil, and tailings." Dr. Morin opines that the proposed methods are "not appropriate, reliable, and safe for the Mercury Study." He adds that the proposed groundwater modelling is similarly unreliable. Dr.

Morin concludes that he expects that the proponent will underestimate the important geochemical input and groundwater flow leaving its Gear Bear site which is “critical for a reliable outcome from the proposed Mercury Study.”

The proponent should not proceed with the Study Plan until there is high quality ML-ARD data and baseline data over multiple years for the model, and a credible monitoring plan in place. This must also be completed before the proponent proceeds with further activities that could cause potential impacts, including impacts to baseline data, for example, AEX construction, road and trail building, etc.

4. **The assimilative capacity of the receiving waters as a mitigation strategy for excess sulphate loading is not supported by the available data.**

The proponent continues to present a mitigation strategy that involves “discharging treated effluent to a large receiving watercourse (Chukuni River) that has a high oxygenation level and high assimilative capacity.” Our experts have commented on this “strategy” in previous submissions, explaining that this presents an erroneous understanding of methylation in aquatic environments. Dr. Branfireun responds in detail in his enclosed report. Dr. Branfireun concludes that:

- The strategies for treating effluent to be discharged to the Chukuni River do not target sulphate, and sulphate production from overburden and waste rock are likely to be greater than the proponent states.

- The proponent’s assessment of the watercourse’s assimilative capacity is inadequate as the proponent uses the average of entire daily discharge records for all of their dilution scenarios. There are potentially dire sulphate concentrations/volumes that could arise as a result of low flows combined with higher than stated effluent sulphate concentrations/volumes.

- The proponent relies on the high oxygenation level of the Chukuni River and does not consider the methylation potential of downstream waters, nor riparian areas and porewater, where this well-oxygenated river will deliver sulphate that may be many times in excess of background levels, in particular, to downstream mercury-sensitive lakes with high mercury methylation potential.

As with other components of this project, the cumulative impacts of this project in the context of other past, present, and planned projects does not appear to have been considered. There are at least five other gold mining projects proposed or operating in this watershed, as well as a pulp mill, sawmill, dams, diversions, clearcut logging, and municipal waste.

As well, the other mitigation measures described in the Study Plan are generally vague, unclear, and incomplete, and the list of potential effects is similarly incomplete and does not include potential effects from road and trail construction, site clearing, soil impacts, and water/dewatering, for example. There is insufficient information available for Grassy Narrows to adequately assess the proposed mitigation measures, and the information provided to date does not satisfy our experts that the proposed measures are effective and safe.

5. **The proposed model that the proponent plans to use to predict changes in sulphate, mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish cannot technically**

deliver on those outcomes.

The Study Plan states that the proponent will rely on the GoldSim software modelling package to "simulate the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project." Our experts raise significant concerns with the GoldSim software, including its inability to be applied to an environmental mercury speciation scenario, and opine that additional information on the model is required before it can be assessed as an adequate model for the methylation studies.

Dr. Morin explains that mercury and sulphate predictions will only be generated at "nodes", the areas where the user-defined "conceptual boxes" connect. This means that the predictions will not simulate waterbodies in their environmental complexity, but simply represent the internal conditions that the proponent "chooses to assume, estimate, and simulate." It is particularly concerning that the Chukuni River will only be modeled at two "nodes", immediately above and below the property boundary. There are no "nodes" in Pakwash Lake nor further downstream where there are concerns of mercury methylation. There are also no nodes at a baseline site that is upstream from the impact of other local mines and therefore reflects uncontaminated conditions. Dr. Morin explains that "because of this "node" approach, important details like an initial dilution zone (a mixing zone) in the Chukuni River between Nodes CHK-1 and CHK-2 cannot be simulated in sufficient detail."

Dr. Branfireun explains that GoldSim "does not appear to ever have been applied to an environmental mercury speciation scenario" and attributes this to the software's model which "cannot incorporate mechanistic sorption/desorption reactions along flow paths, the biomethylation process, nor the complex interaction between mercury and sulphate." Dr. Branfireun concludes that, as a result, "the model proposed can never be successfully applied in the manner that is proposed. […] A mass balance model *cannot* by definition incorporate mechanistically the input and removal processes for mercury, and *cannot* address the biogeochemical aspects of mercury methylation across the landscape which are at the root of the potential impacts associated with the Great Bear proposal."

The Study Plan, and its model, also appear to ignore a number of parameters beyond THg, meHg, and sulphate which can impact methylation dynamics including DOC, light penetration, temperature, pH, and other parameters.

We are not satisfied that the GoldSim software proposed is appropriate or technically able to apply to the circumstances and produce a useful prediction. We are concerned that the technical limitations of the software, as well as the manner in which the proponent intends to use the software, will not produce reliable, accurate, or useful predictions. Our concerns are heightened given the ongoing data quality problems in relation to the Great Bear Project – flawed data will lead to flawed results, regardless of the software chosen.

<u>Conclusion</u>

Dr. Branfireun concludes in his report:

> "We have a water quality model that is not capable of predicting mercury biogeochemical processes, that is dependent on background data and proposed monitoring that is insufficient. The outcome will be the inevitable future conclusion by the Proponent that the combination has led to an inability to adequately predict changes in methylmercury concentrations in fish because of 'uncertainties' in GoldSim output, and "unforeseen

> complexities" in coupling abiotic and biotic compartments. The reality is that these uncertainties and complexities are completely foreseeable as outlined here. […] I conclude that the TISG's requirement that the Proponent provide *a detailed and robust analysis on the potential for project contributions to methylmercury production in downstream watersheds* has not been met based on the information provided in the Mercury Plan."

In light of our experts' opinions, we are concerned with this Study Plan and require additional time to complete a fulsome review and engage with our experts in a more in depth manner, and to engage with our other experts and our community.

We reiterate our request for a 90-day extension to provide comments. It is not prudent nor rational to proceed with a Mercury Study which is built on erroneous, incomplete, and inaccurate data and which uses flawed methodology that is unable to adequately address the biogeochemical aspects of mercury methylation across the landscape as required.

We expect that the proponent will not move forward with this Study Plan, the proposed studies, or any additional work on the site that may cause adverse effects prior to receiving and meaningfully integrating our comments.

BUILDING A LEGACY IN RED LAKE, ONTARIO

GREAT BEAR PROJECT

Proposed Open Pit and Underground Gold Mine

Fisheries Habitat Offsetting and Compensation Measures Request for Feedback

KINROSS

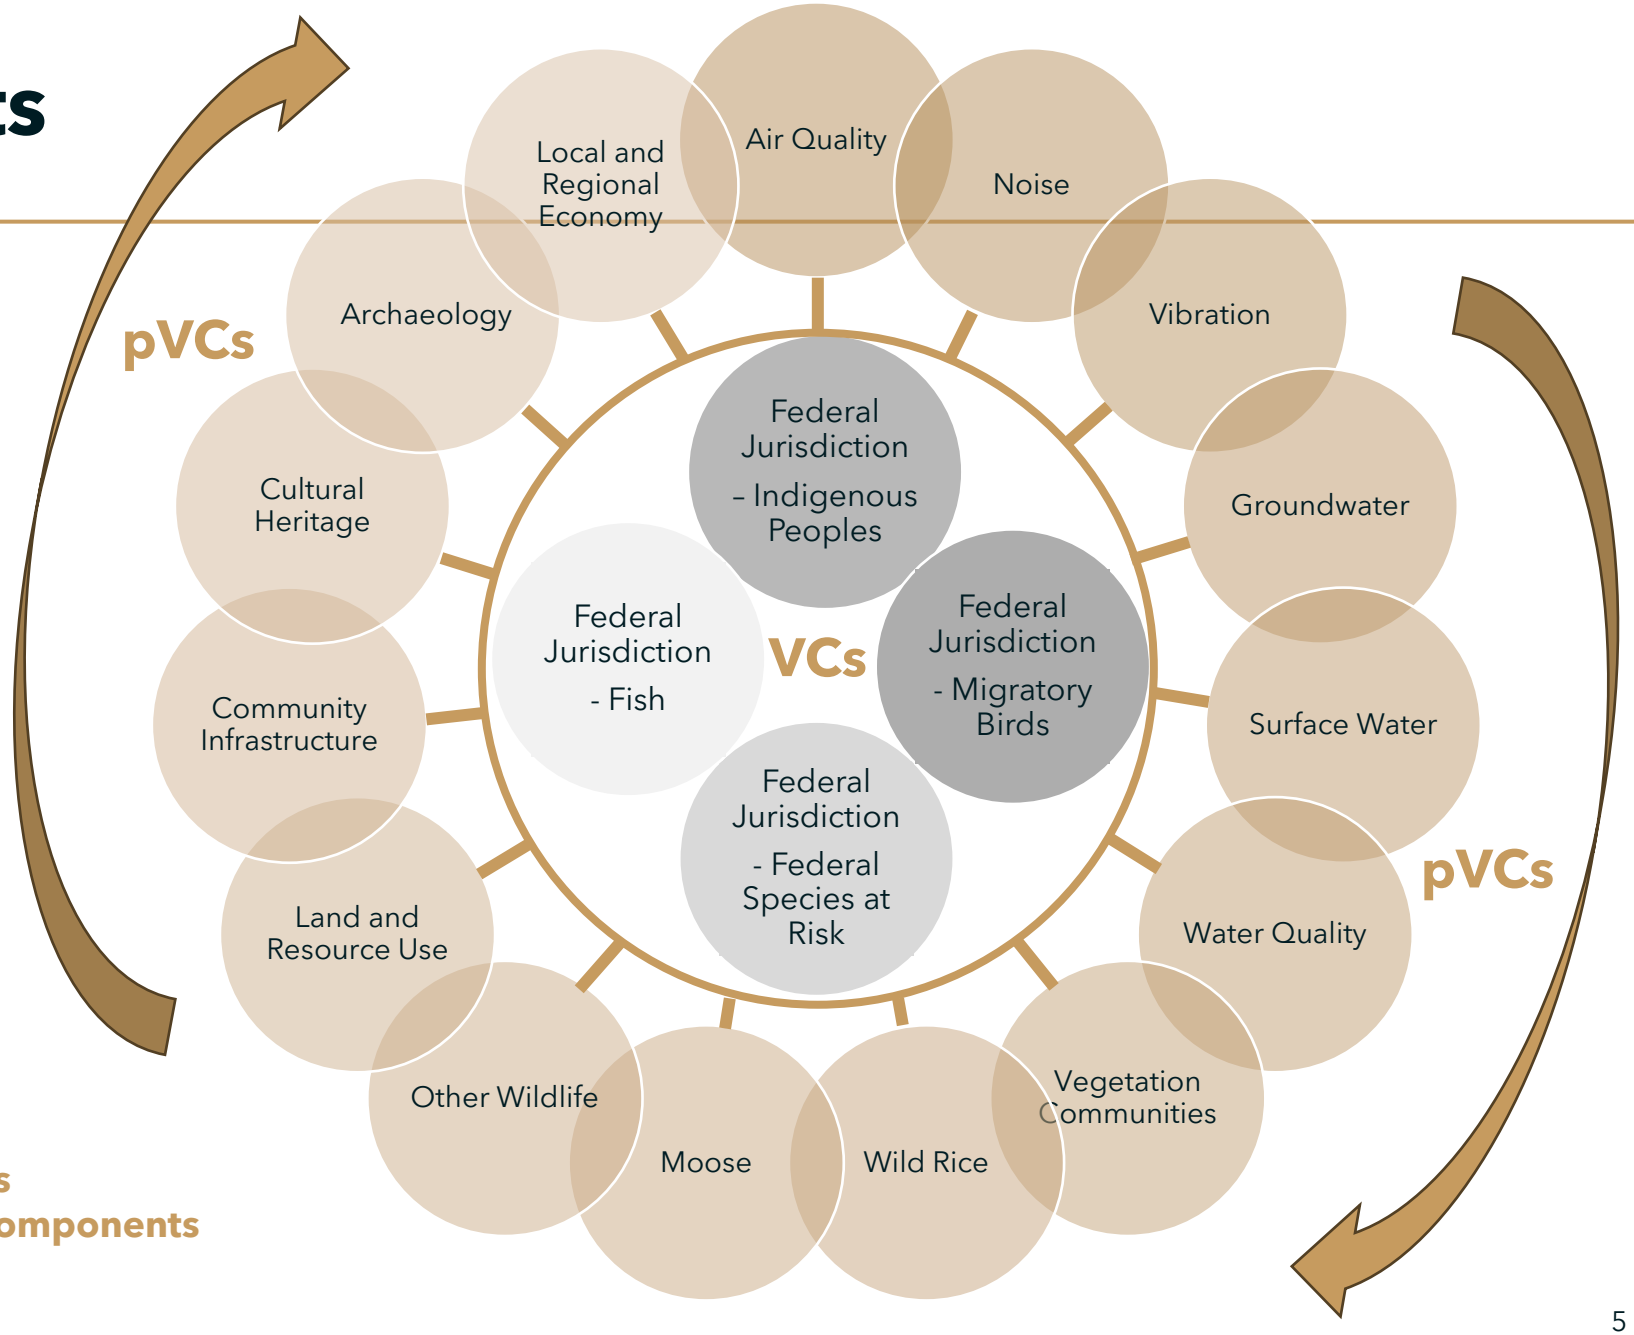
Current Status of Federal Approval

- Great Bear received our Tailored Impact Statement Guidelines on August 1, 2024, these guidelines provide the roadmap for the Impact Statement.
- The purpose of the Impact Statement is to identify and assess impacts of the project and the measures proposed to mitigate those effects.
- In this phase the Impact Statement will be drafted, with engagement and consultation on key elements like alternatives, design, closure, and fish compensation. This work is framed around Valued Components and Pathways.

KINROSS

Valued Components

- **Valued Components** frame the assessment of the Project's potential impacts on both the biophysical and human environment with special attention given to aspects under Federal jurisdiction.
- **Pathway Valued Components** encompass a wide range of considerations, including terrestrial and aquatic ecology, water resources, vegetation, the physical environment, human well-being, community development, and Indigenous peoples.
- The Impact Assessment takes into consideration these pathways individually assessing while considering the implementation of avoidance and mitigation measures to reduce or eliminate any potential effects.



VCs: Valued Components
pVCs: Pathway Valued Components

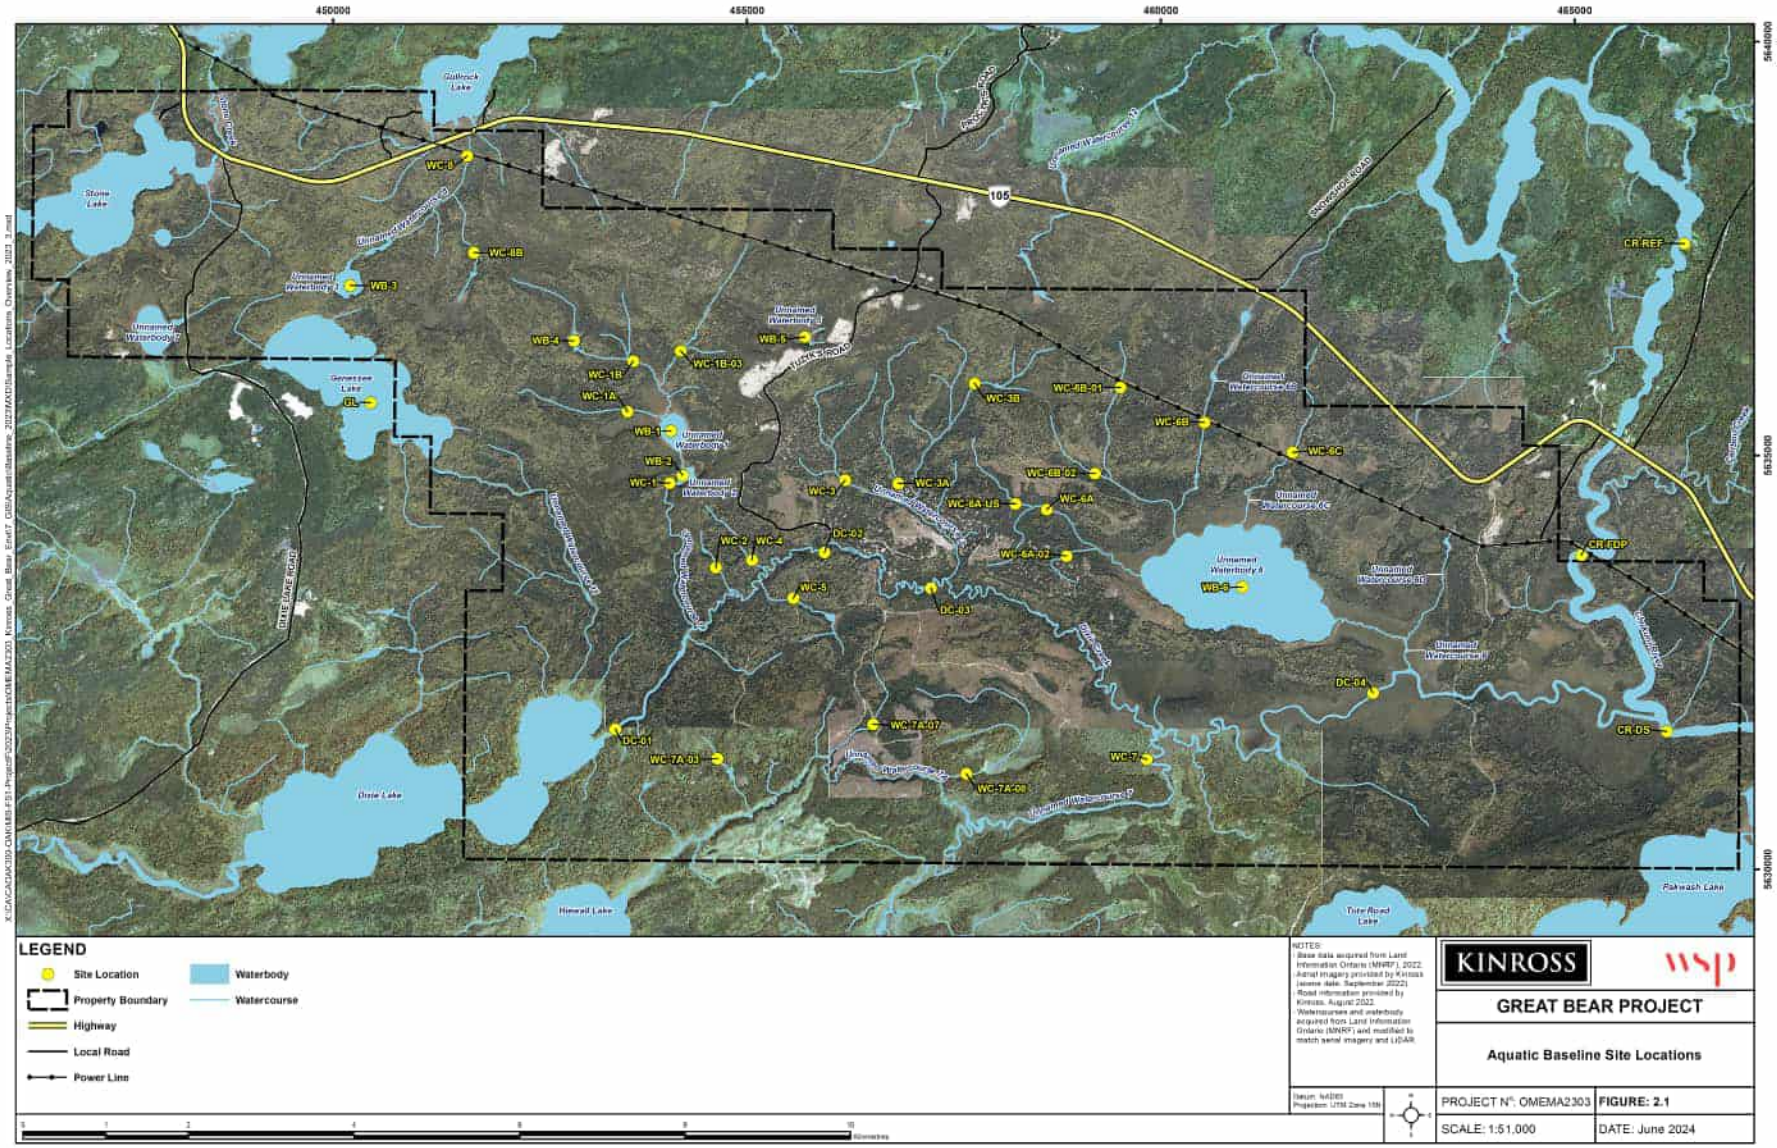
KINROSS

Fisheries Baseline

Field Studies Overview

(2022–2023):

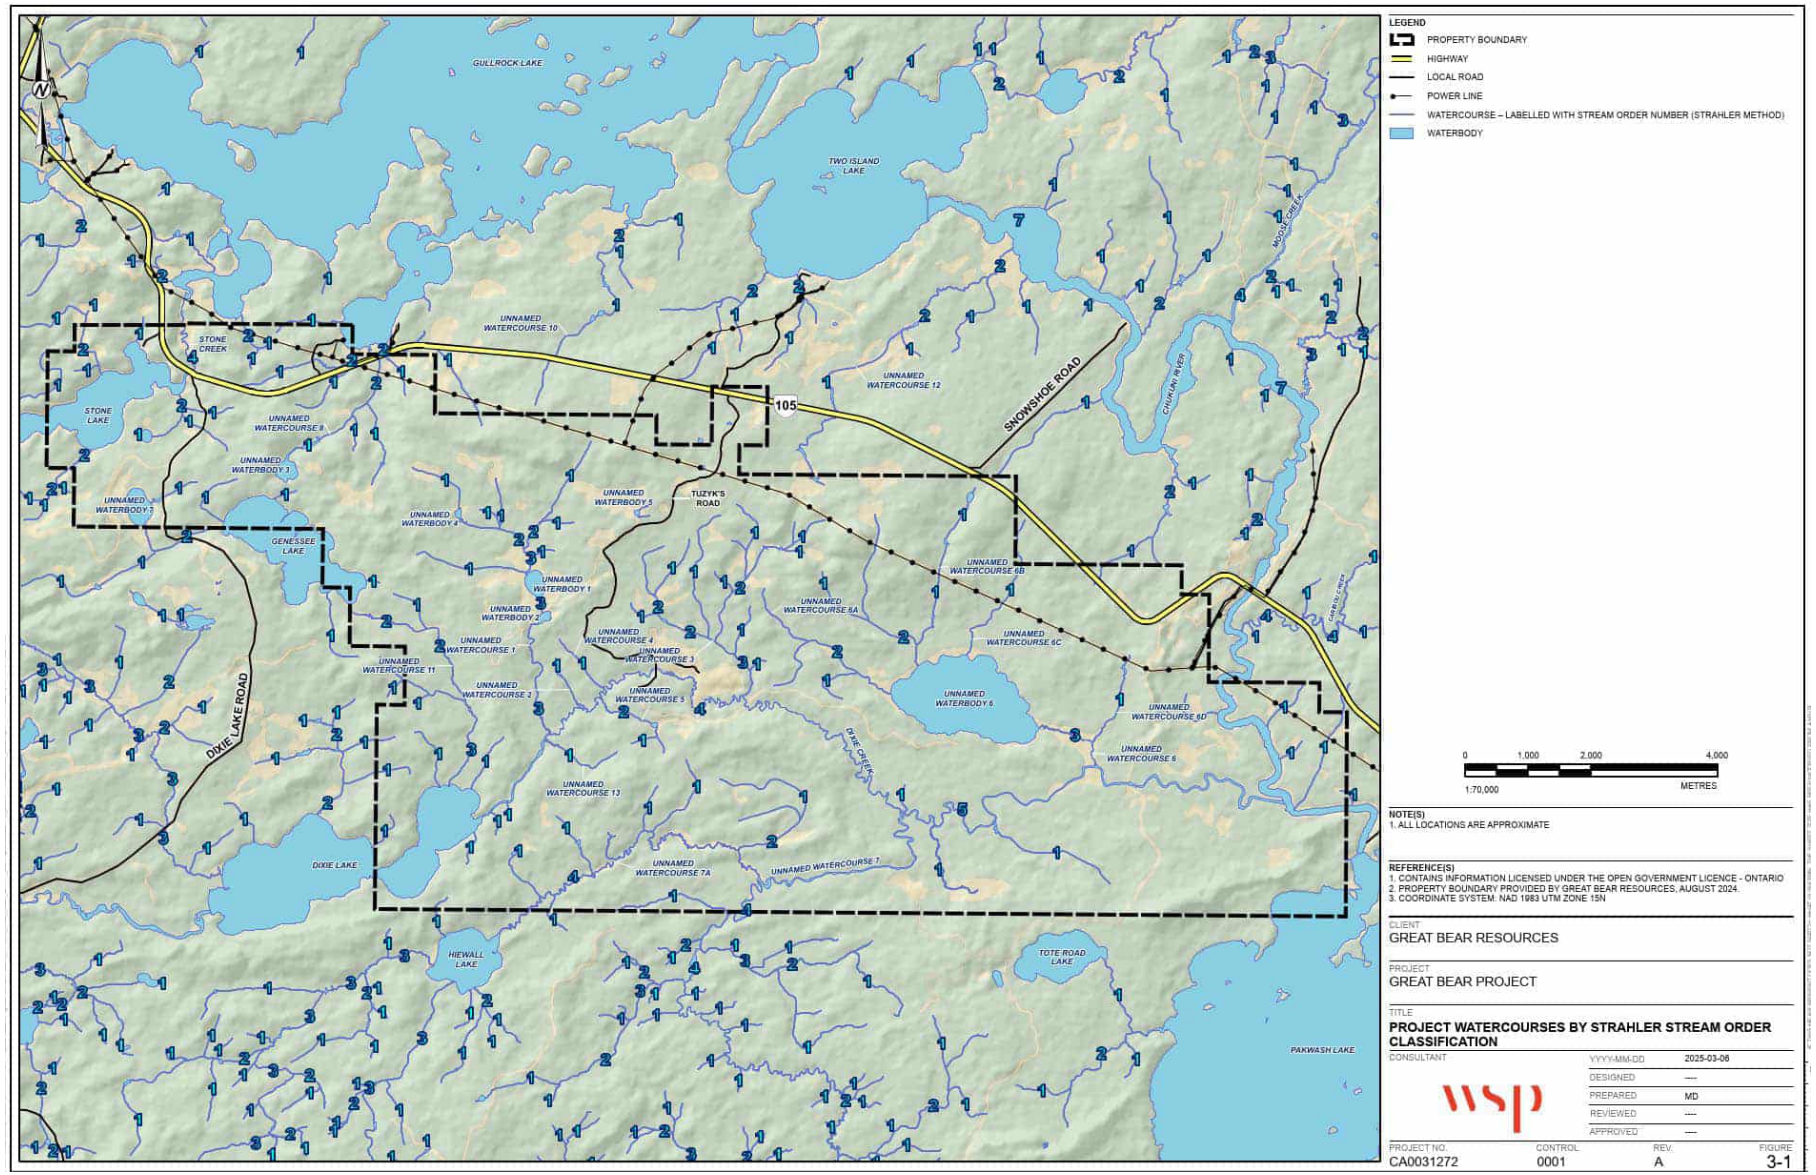
- Great Bear has completed extensive baseline studies on Fish and Fish Habitat in the project area.
- Sampled within and beyond the proposed project footprint to establish baseline conditions.
- Conducted habitat assessments at key locations during 2023.
- Integrated eDNA sampling in 2023 to enhance traditional fish community methods (minnow traps, electrofishing).



Stream Orders

Stream order is a numbering system that tells us how big the creek or river is by adding up the number of creeks that have joined together.

- We have used stream order to show aquatic baseline information in the following pages
- Small numbers such as 1 and 2 mean that the creek is small; sometimes there is no water or fish present.
- Larger numbers such as 5, 6 and 7 mean that numerous small creeks have joined together to make a large creek or river.
- Most of the creeks in the Project area are small, with stream orders of 3 or less. Dixie Creek is a bit larger with stream orders of 4 and 5



Project Area Fish Community Structure

Forage and Baitfish

- Blackchin Shiner
- Blacknose Shiner
- Bluntnose Minnow
- Brook Stickleback
- Central Mudminnow
- Common Shiner
- Emerald Shiner
- Fathead Minnow
- Finescale Dace
- Golden Shiner
- Iowa Darter
- Johnny Darter
- Lake Chub
- Mimic Shiner
- Northern Pearl Dace
- Northern Redbelly Dace
- Rainbow Smelt
- Silver Redhorse
- Shorthead Redhorse
- Slimy Sculpin
- Spottail Shiner
- Trout Perch
- White Sucker

Intermediate Sportfish

- Burbot
- Cisco
- Rock Bass
- Yellow Perch
- Mooneye

Top Trophic Level Sportfish

- Walleye
- Lake Whitefish
- Northern Pike
- Small Mouth Bass
- Muskellunge
- Lake Sturgeon
- Lake Trout

INLAND PONDS AND CREEKS → INTERMEDIATE CREEKS AND LAKES (Dixie Creek/ Waterbody 6) → LARGER RIVERS AND LAKES (Chukuni River / Pakwash Lake

Project Area Fish Community Structure by Stream Order (stream size)

Inland Ponds and Creeks

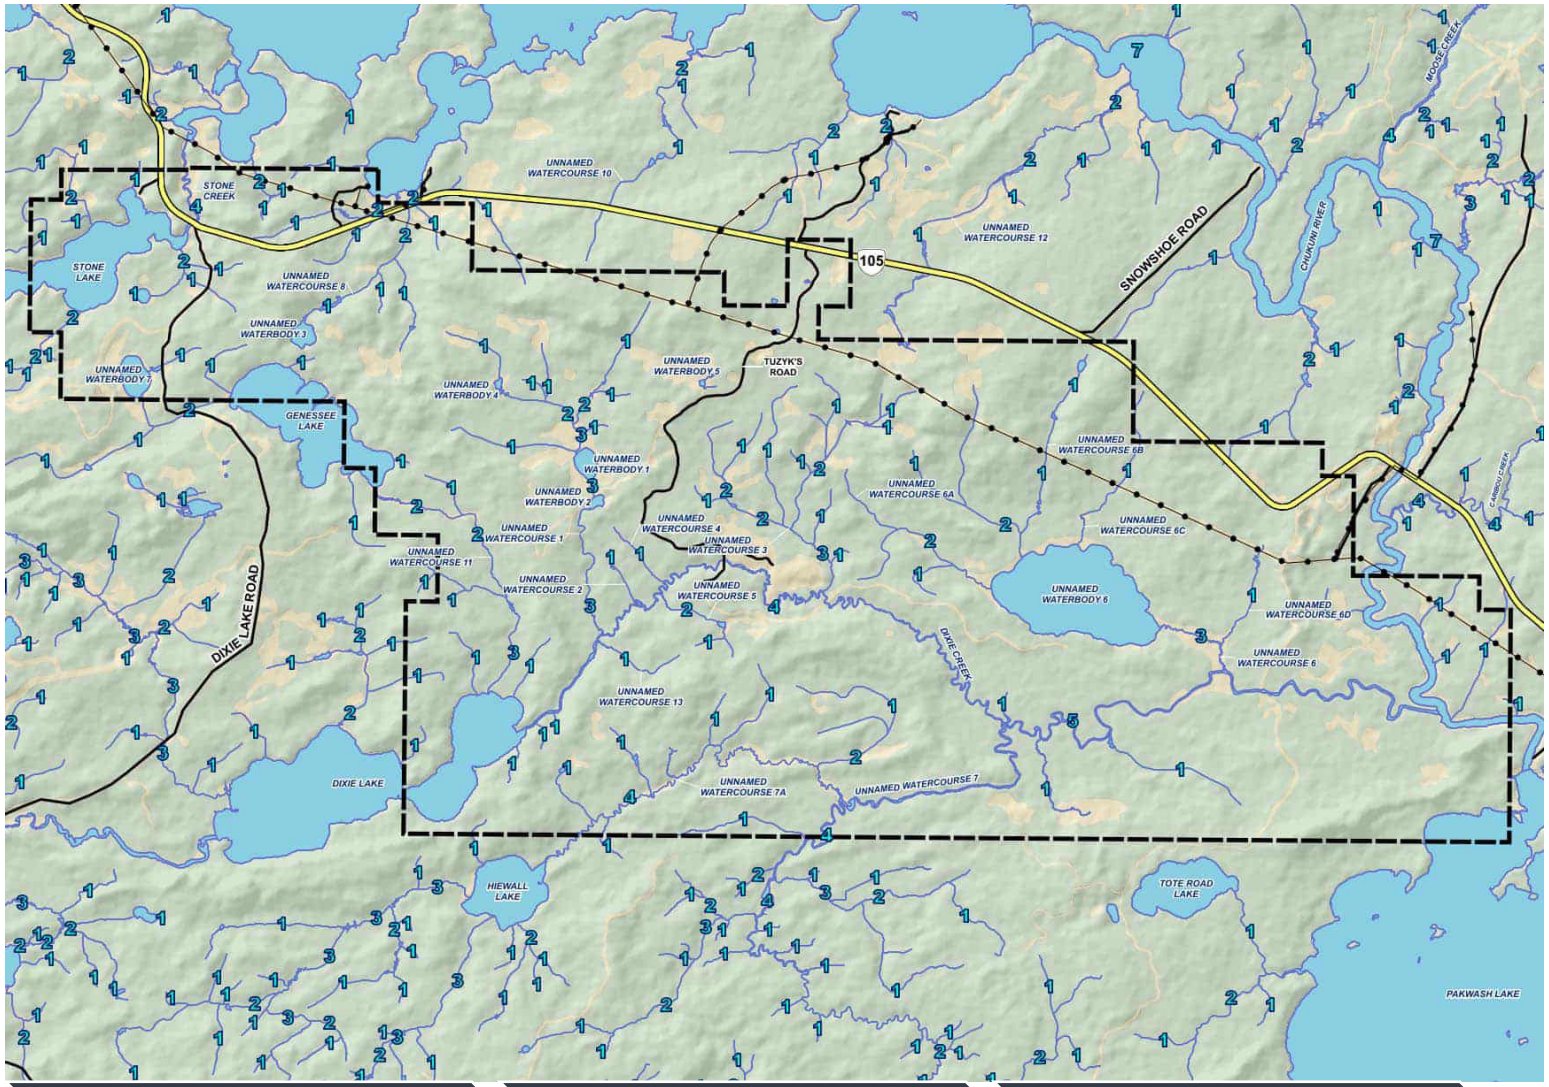
Stream orders 1-2	No fish to small bodied fish present , (i.e., minnows, mudminnow, stickleback)

Intermediate creeks and lakes

Stream orders 3-4	Small bodied and some larger fish (i.e, mooneye, suckers, northern pike, yellow perch, rock bass, burbot)

Larger Rivers and Lakes

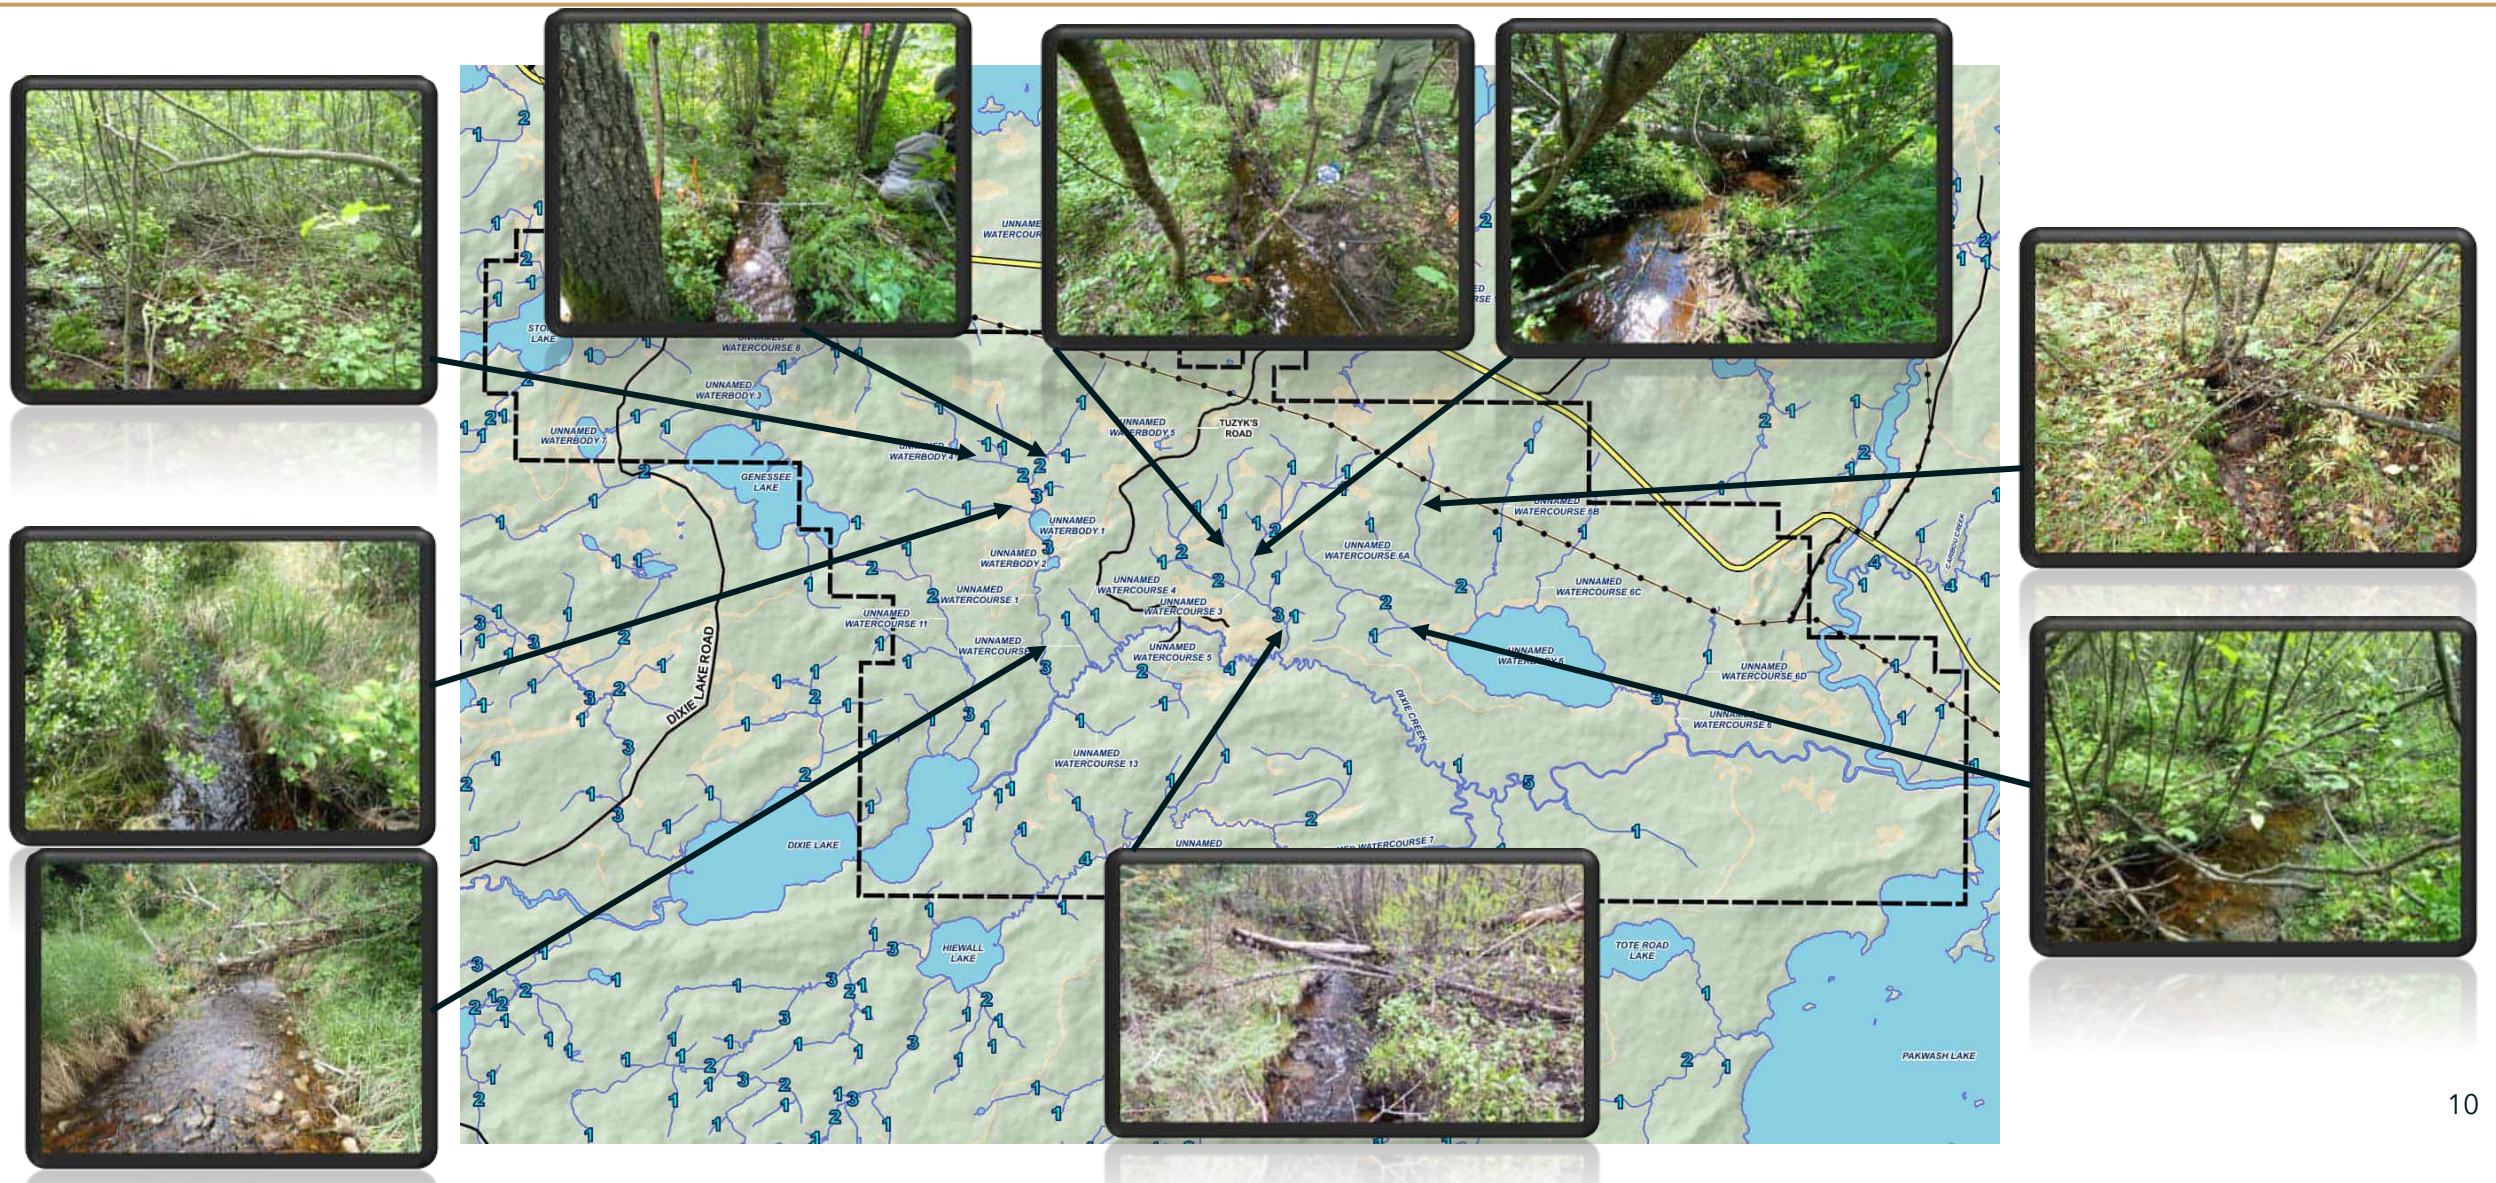
Stream orders 5 and larger, large lakes such as Dixie, Genessee, Pakwash, Gullrock)	Diverse fish communities including small bodied fish and large cool water and cold water sportfish (walleye, northern pike lake whitefish)



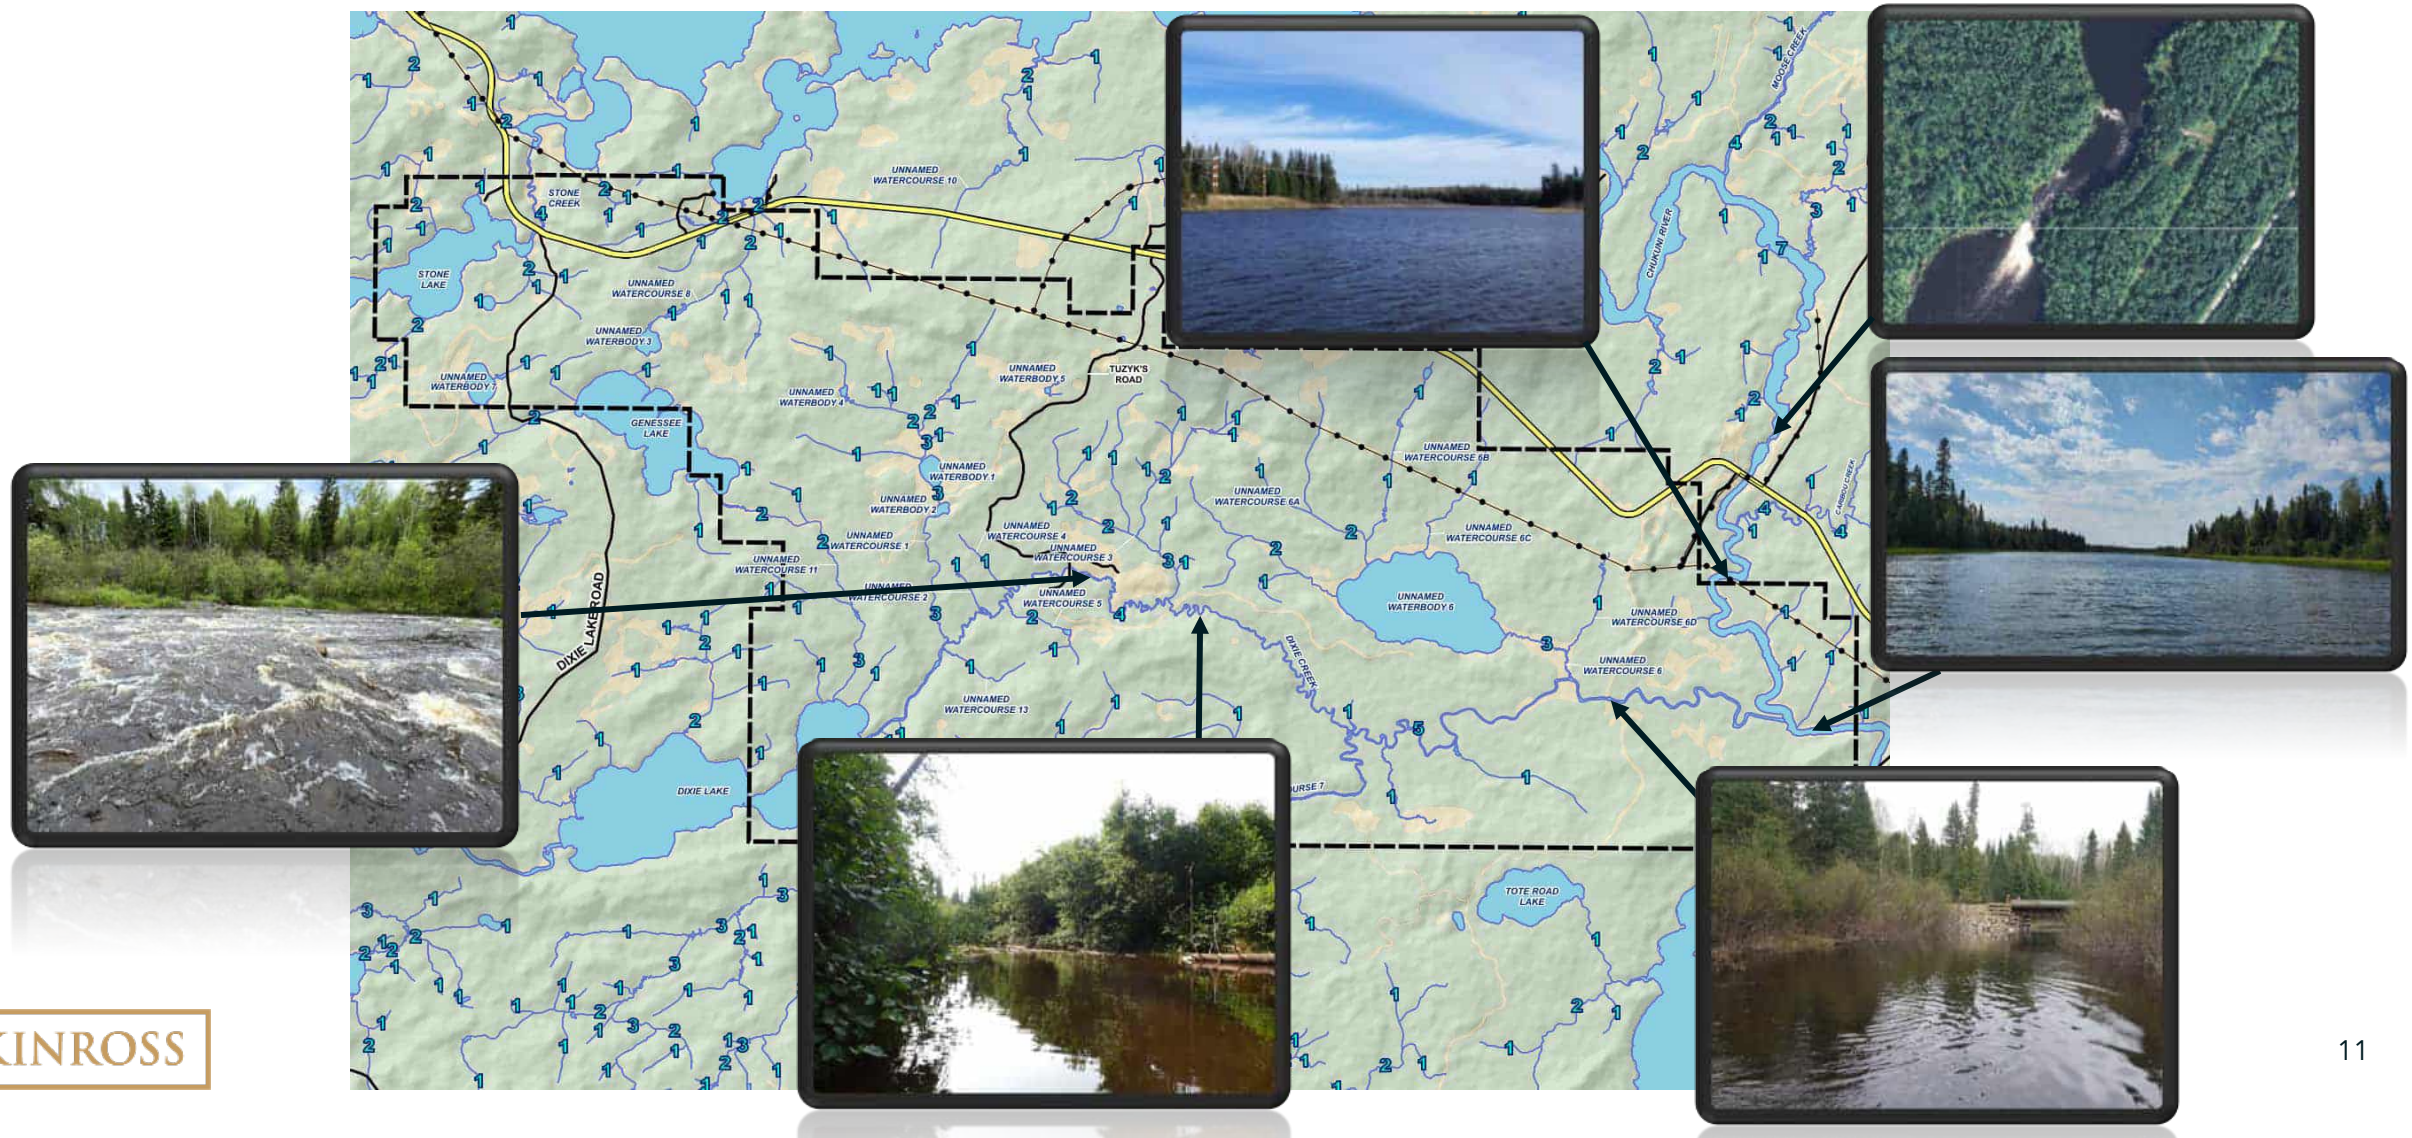
LEGEND
- PROPERTY BOUNDARY
- HIGHWAY
- LOCAL ROAD
- POWER LINE
- WATERCOURSE – LABELLED WITH STREAM ORDER NUMBER (STRAHLER METHOD)
- WATERBODY

INLAND PONDS AND CREEKS → INTERMEDIATE CREEKS AND LAKES (Upper Dixie Creek/ Waterbody 6) → LARGER RIVERS AND LAKES (lower Dixie Creek, Chukuni River / Pakwash Lake

Aquatic Habitat – Small Creeks (stream Order 1-3)

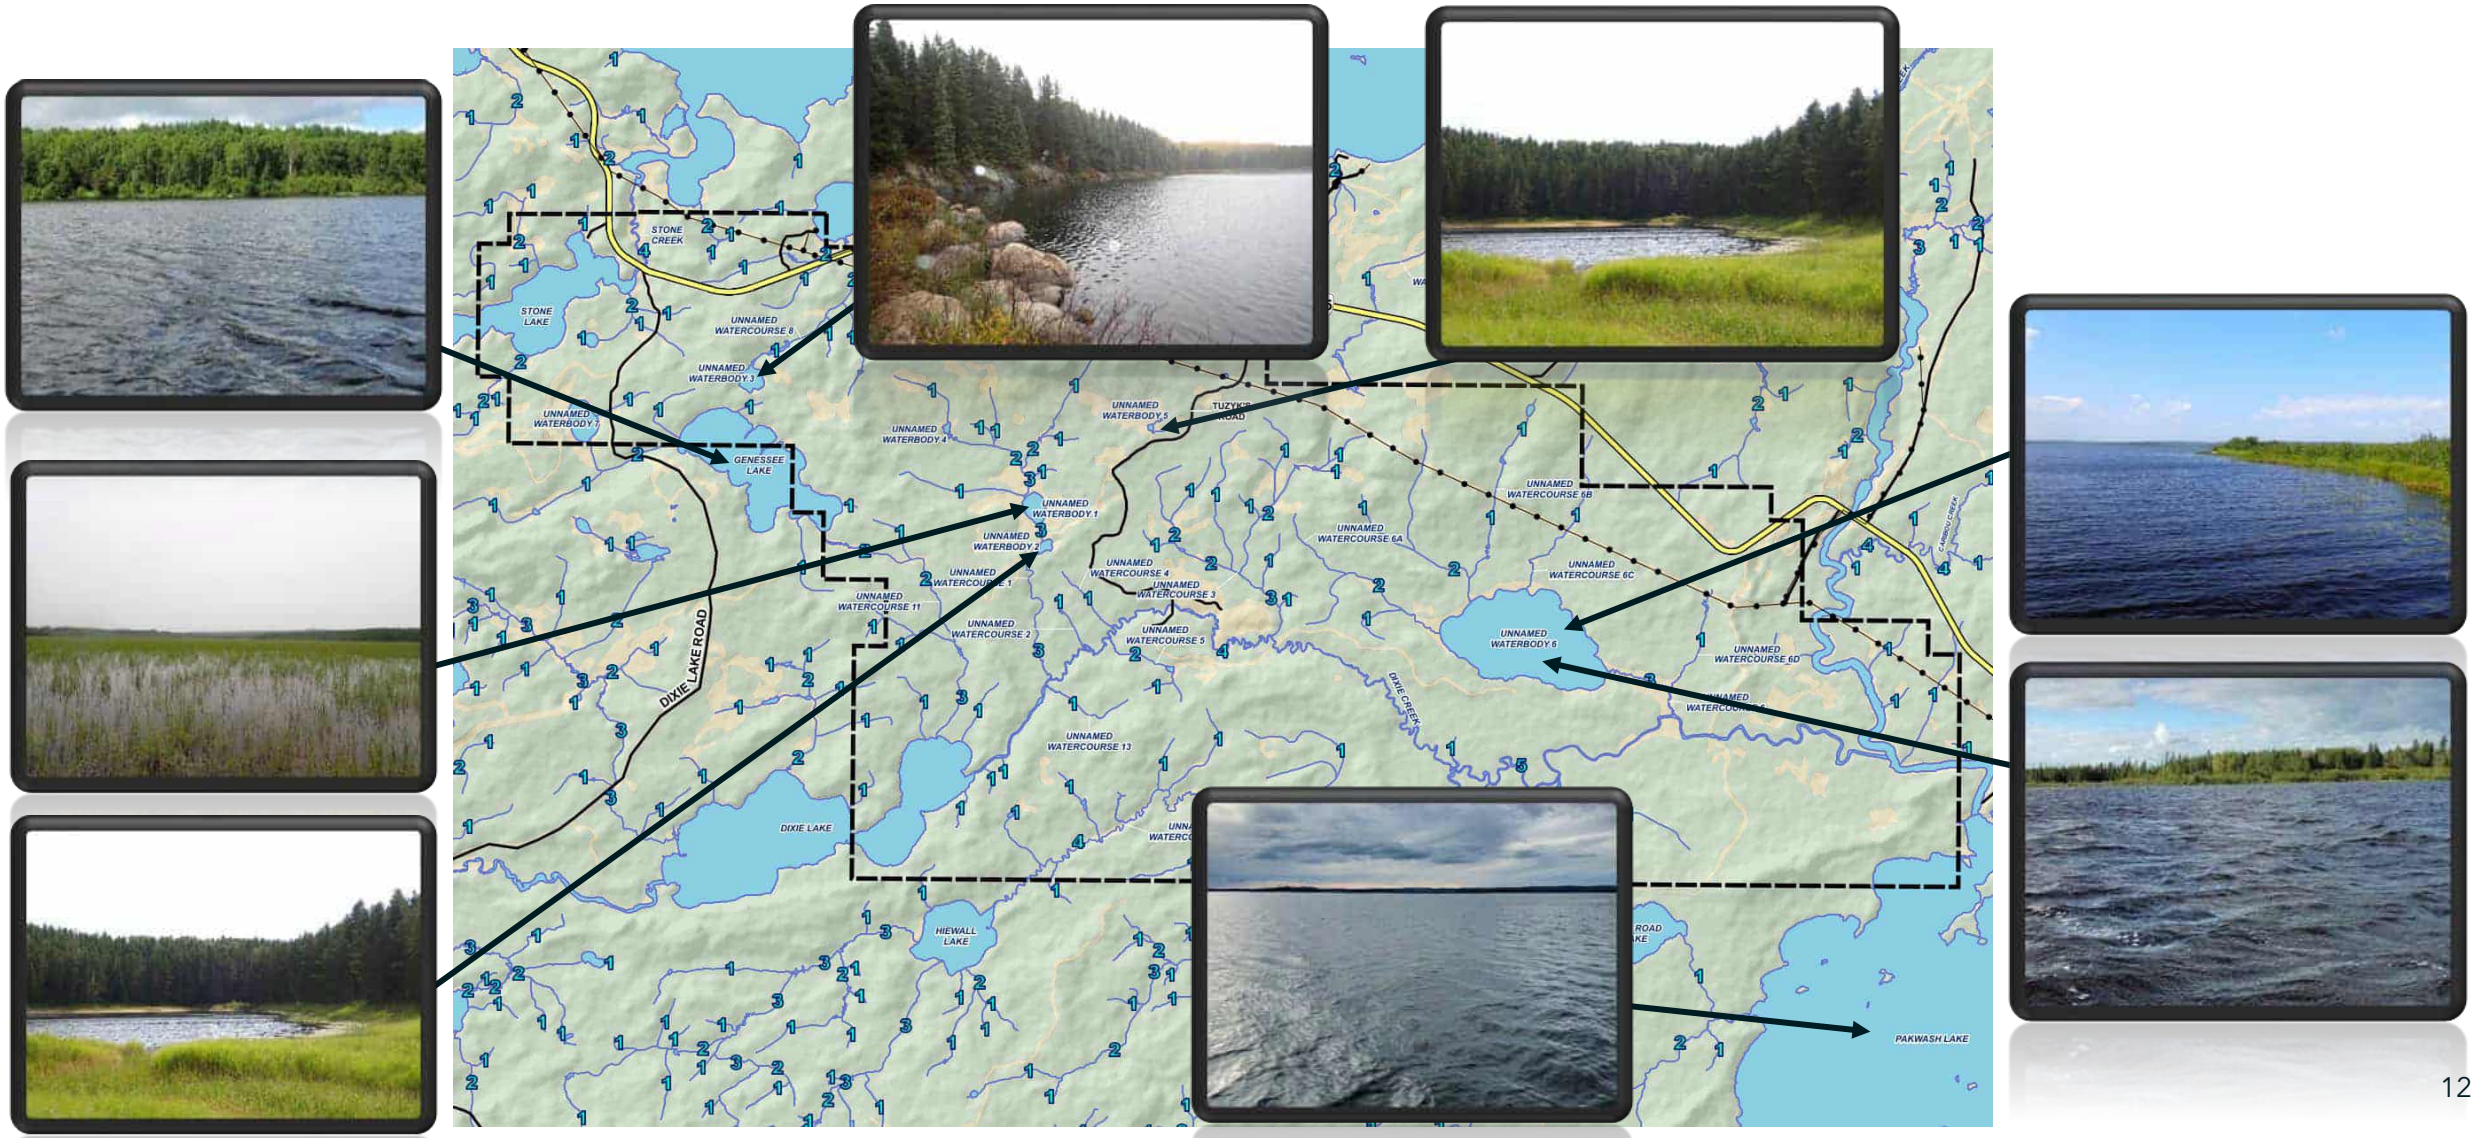


Aquatic Habitat – Larger Creeks and Rivers



KINROSS

Aquatic Habitat – Ponds / Lakes



Fish Habitat Impacts and Offsetting

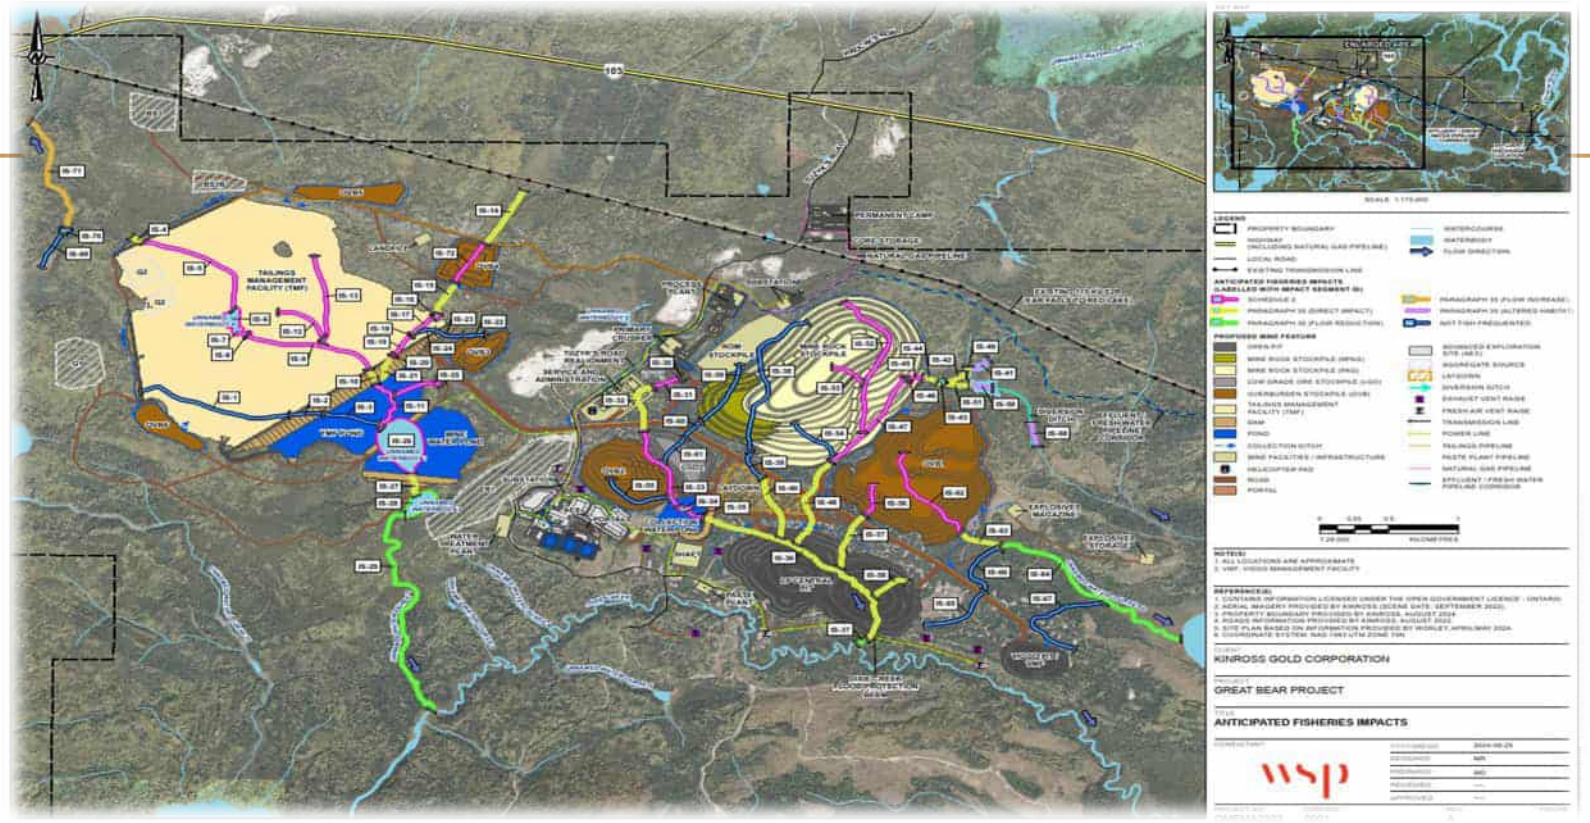
The project will result in some impacts to fish and fish habitat.

We propose to develop offsetting measures (replacing or improving fish habitat) to counterbalance the impacts.

The next 2 pages show the impacts to fish habitat that will occur from the project, and the types of fish habitat offsetting that can be considered.

Preliminary Impacts

- The proposed project is expected to impact approx. 20 ha of fish habitat.
- To offset these impacts, Kinross Great Bear must create new or enhance existing fish habitat.
- The following slides are created to provide examples of potential offsetting measures.
- **We are looking to the community for feedback and suggestions.**



Effect Type	Predicted Schedule 2 and HADD Area (m^2)	Predicted Schedule 2 and HADD Area (ha)
Schedule 2 Total	141,199	14.12
Section 35 Total	56,647	5.66
Not Fish Frequented *	15,882	1.59
Combined Schedule 2 and Section 35 Total	**197,846**	**19.78**

KINROSS

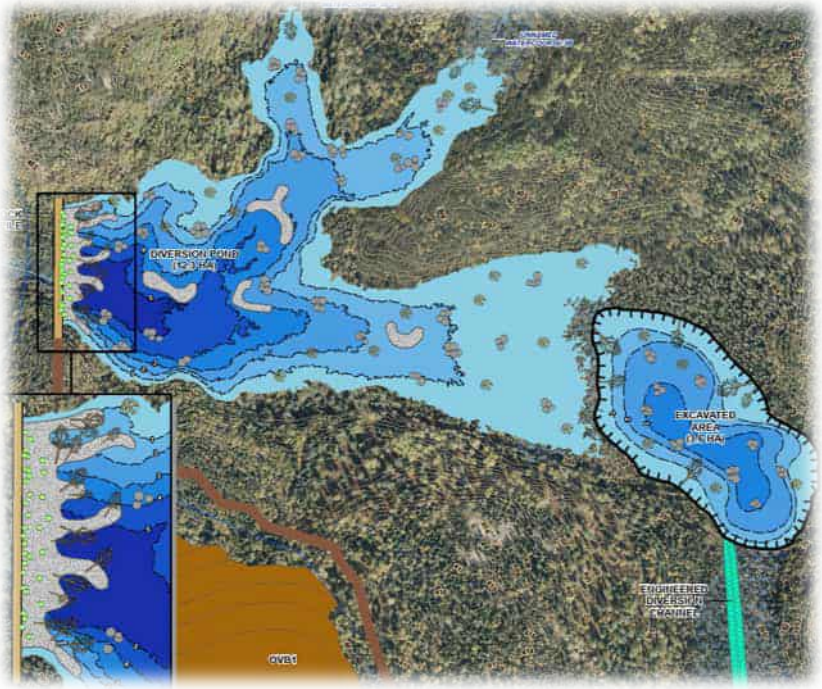
Types of Offsets and Compensation

Measures to offset may be grouped into four general categories	
Habitat Restoration and Enhancement	▪ Add habitat features (boulder clusters, tree piles, spawning stone) ▪ Stabilize stream banks ▪ Remove barriers to fish migration created by people
Habitat Creation	▪ Create new habitat inland or expand existing aquatic habitat
Chemical or Biological Manipulations	▪ Includes chemical treatment for water quality issues and stocking programs, constructed wetlands or control of invasive species
Complementary Measures	▪ Actions like data collection and scientific research related to maintaining or enhancing the conservation and protection of fish and fish habitat. Only considered where there are limited opportunities for on-the-ground measures to offset fish and fish habitat residual effects and can only represent 10% of total offset amount.

Examples

The following examples, specific to the Great Bear Project area, have been developed by WSP for your consideration.

Candidate Offset Measures – New Ponds



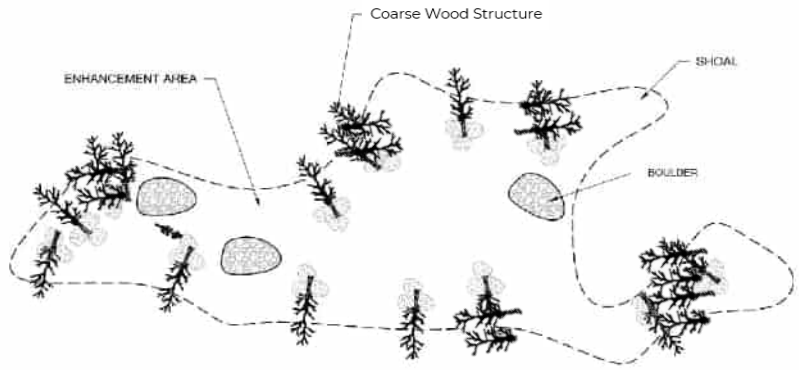
Replace the small lakes and ponds most effected by the project in the same general area of the Project,

The diversion Pond will pass clean water around the site and make a new pond.

More ponds can be excavated beside Dixie Creek.

Use Rocks and trees to provide natural cover for fish

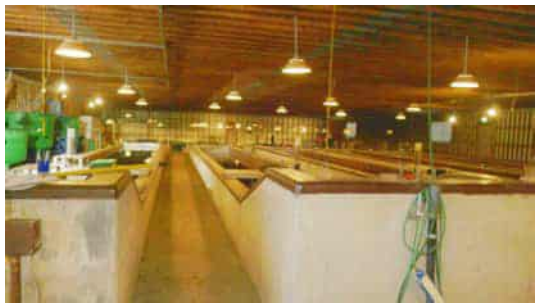
Rock Piles and shoals

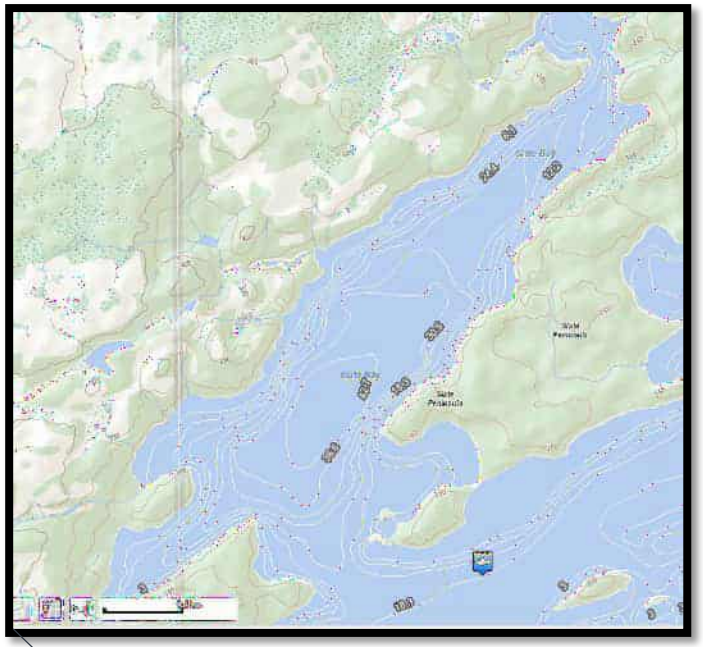


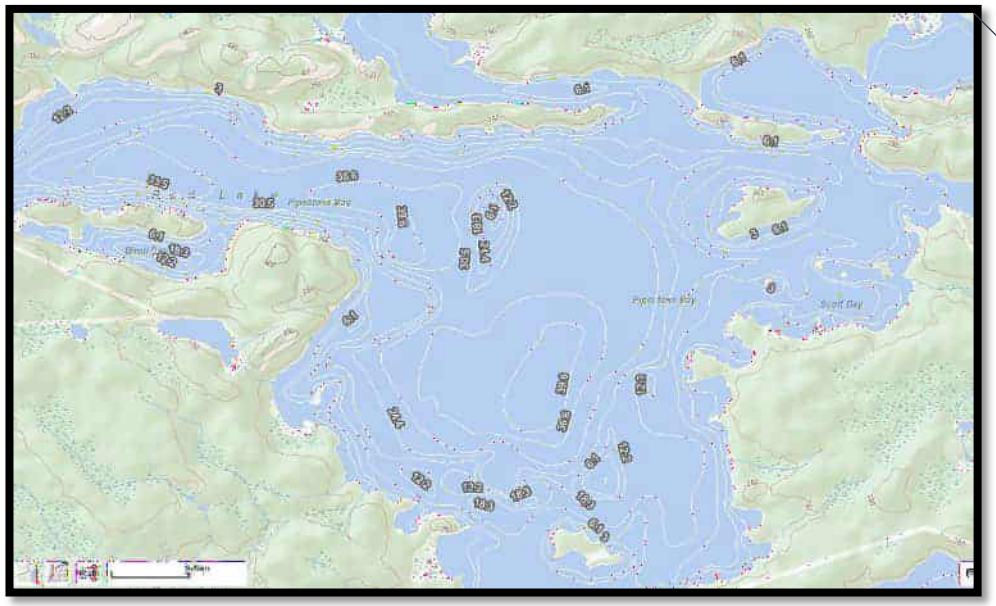
Red Lake Enhancements – Restore Lake Trout Fishery

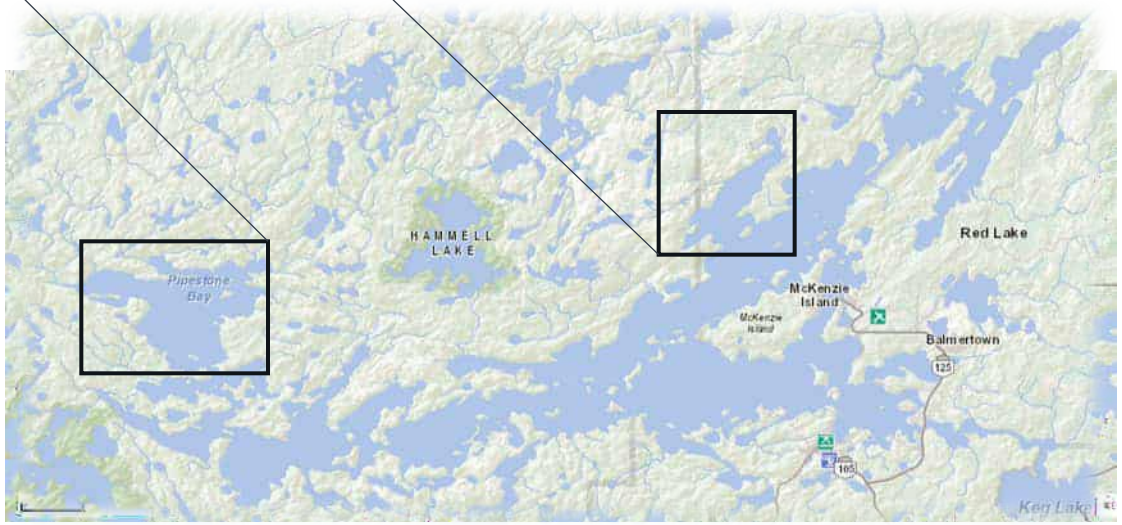
Potential Measure Highlights

- Enhance important life history habitats in Slate Bay
- Seed natural or constructed spawning shoals with fertilized eggs from native Lake Trout.
- Support hatchery efforts by MNR. Look at potential to help develop a hatchery that is local to Red Lake to address stock availability bottleneck.





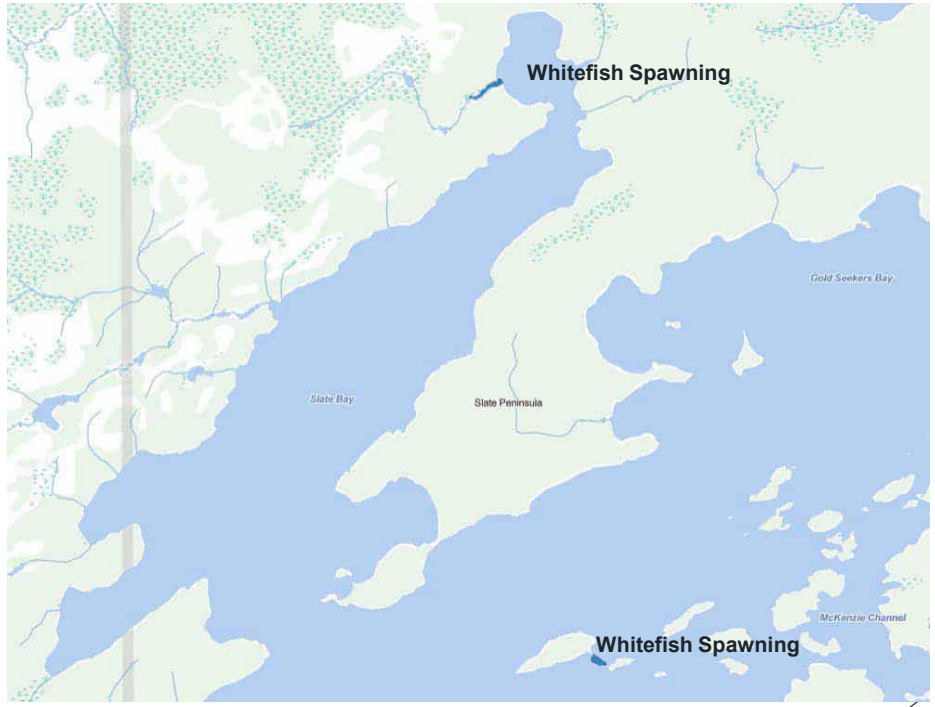


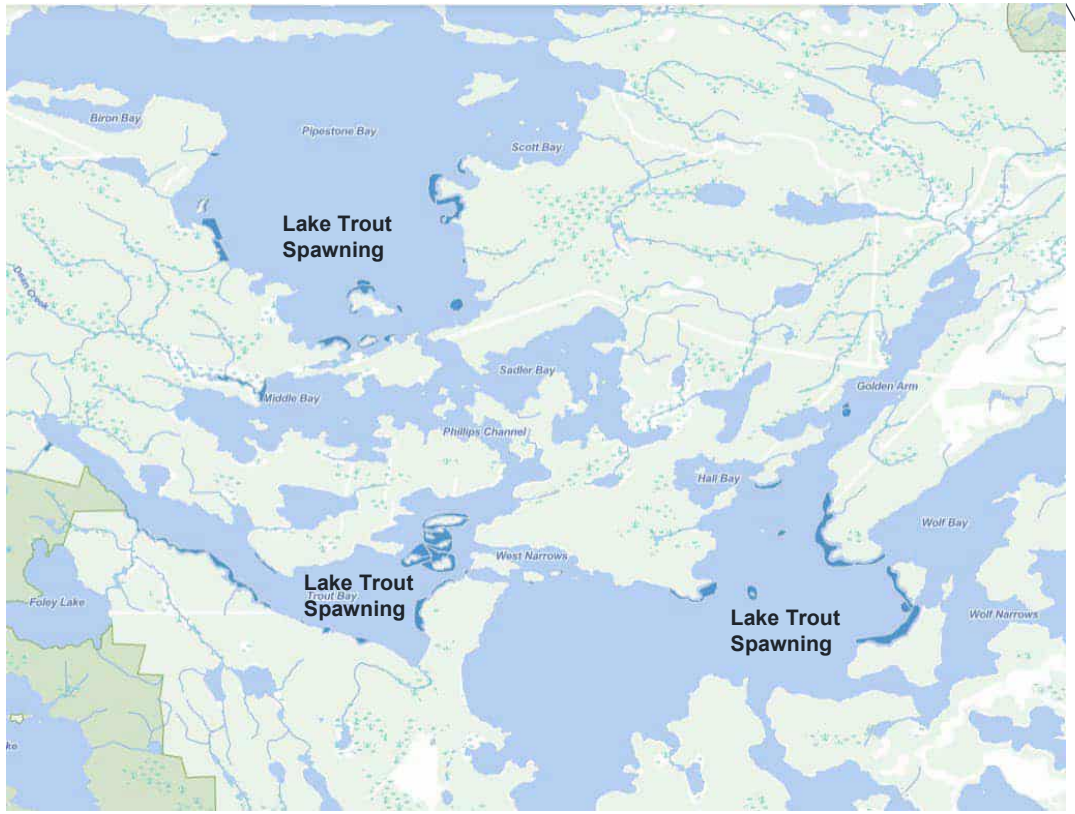


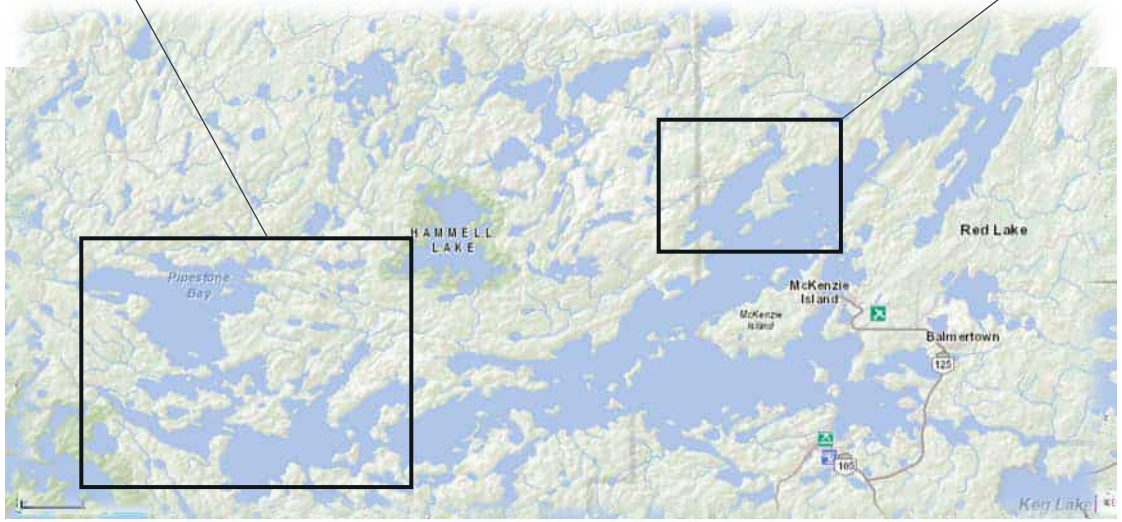
Red Lake Enhancements – Restore Lake Trout Fishery

Potential Measure Highlights

- Historic (known) spawning areas are concentrated near Pipestone Bay to Wolf Bay.
- Water depths to and within Slate Bay are good for supporting Lake Trout.







Other Examples

The following examples have been developed by WSP for your consideration. These are not specific to the Project area but are similar projects in other parts of Ontario.

Are there locations in and around your community that could benefit from a similar initiative?

Examples of Restoration and Enhancement

Culvert and Fish Barrier Replacement with Bridge and Spawning Area

Examples of Restoration and Enhancement

Constructed Riffles - Spawning Substrate

- Can be built to improve habitat complexity between natural waterbodies or constructed as part of new habitat creation (spawning, forage and passage habitat)

Examples of Restoration and Enhancement

Lake Trout and Walleye Spawning Shoal Enhancement

Examples of Restoration and Enhancement

Realigned Creek – Enhanced Features

Natural limitations are opportunities for enhancement:

- What are natural limitations? Enhancements maximize the benefits from a measure.
- Determine success criteria at the start - are you making habitat (m^2) or fish (number of fish) **or both**?

Creek Replacement with enhanced habitat increased total habitat area

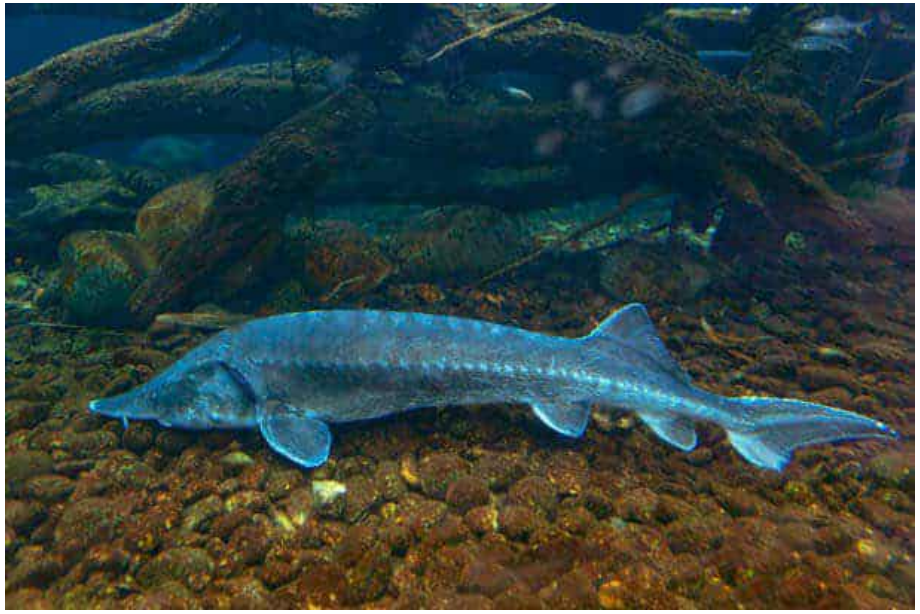
Enhancement resulted in greater than 100% increase in trout

Examples of Complimentary Measures

Research and Development - data collection and scientific research related to maintaining or enhancing the conservation and protection of fish and fish habitat.

eDNA - although becoming more common in surveys to assess species presence, environmental DNA (metabarcoding and PCR) sampling can be an important research tool for species distribution and Species at Risk investigations.

Science Gaps - collecting data on a species or habitat where a science gap exists.



Examples of Habitat Creation

Low berm impoundment

- ✓ **Provides complex wetland and fish habitat (ecosystem approach)**
- ✓ **Makes use of existing topography**

Low Berm Structure at Construction

Examples of Habitat Creation

Pond / Lake Excavation – Within low lying areas to match natural landscape

Basin Extension to Existing Lake

Other Habitat Considerations (Ecosystem Approach)

Tree Snags and Cavity Trees

Rock Piles

Brush Piles

Turtle Nesting Structures

Engineering, Social and Ecology Goals need to Match

Consider the function and uses of the measures into the engineering:

- Beaver are expected to colonize diversions channels
- People may have access and a desire to harvest fish
- Consider long-term risk and management.

How do we compile a list of Candidate Offset Measures?

1) **Talking with First Nation Communities, Local Natural Resource User Groups (e.g., fish and game clubs, Outfitters), Provincial Regulators (e.g., MNR) and Others.**

   - Create a list of measures, as much detail as able
   - Are there any baseline data collected?
     - ✓ Add to the decision matrix…

2) **Candidate Measures are Assessed Using a Matrix**

   - ✓ Relevance of measures to project development
   - ✓ Alignment with First Nations and stakeholder interests
   - ✓ Simplicity of construction and monitoring
   - ✓ Compatible with surrounding land use
   - ✓ Constructability and land tenure
   - ✓ Cost Implications

Candidate Measures are ranked using a (1) to (6) scale, with the cumulative score providing a list of highest to lowest rankings.

Attention: Aaron MacDonnell
Director, Environmental Services
Kinross Gold Corp.

Dear Aaron MacDonnell,

RE: Grassy Narrows' Collective Rights

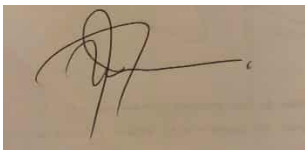
On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows"), we write in relation to your Company's engagement with our community.

We have recently been made aware that representatives from your Company have been approaching individual Grassy Narrows members and trapline holders with respect to your proposed Great Bear Gold Project.

As you know, Grassy Narrows Chief and Council have provided the Land Protection Team with a mandate to engage with your Company with respect to this Project on behalf of Grassy Narrows First Nation. Aboriginal and Treaty rights are communal rights and the duty to consult in regard to these rights is owed to the community as a whole.

We expect that you will respect Chief and Council's direction and continue to engage with the Land Protection Team with respect to Grassy Narrows' inherent, Aboriginal, and Treaty rights.

Miigwetch,



Joseph Fobister
Lead Negotiator, Grassy Narrows Lands Protection Team

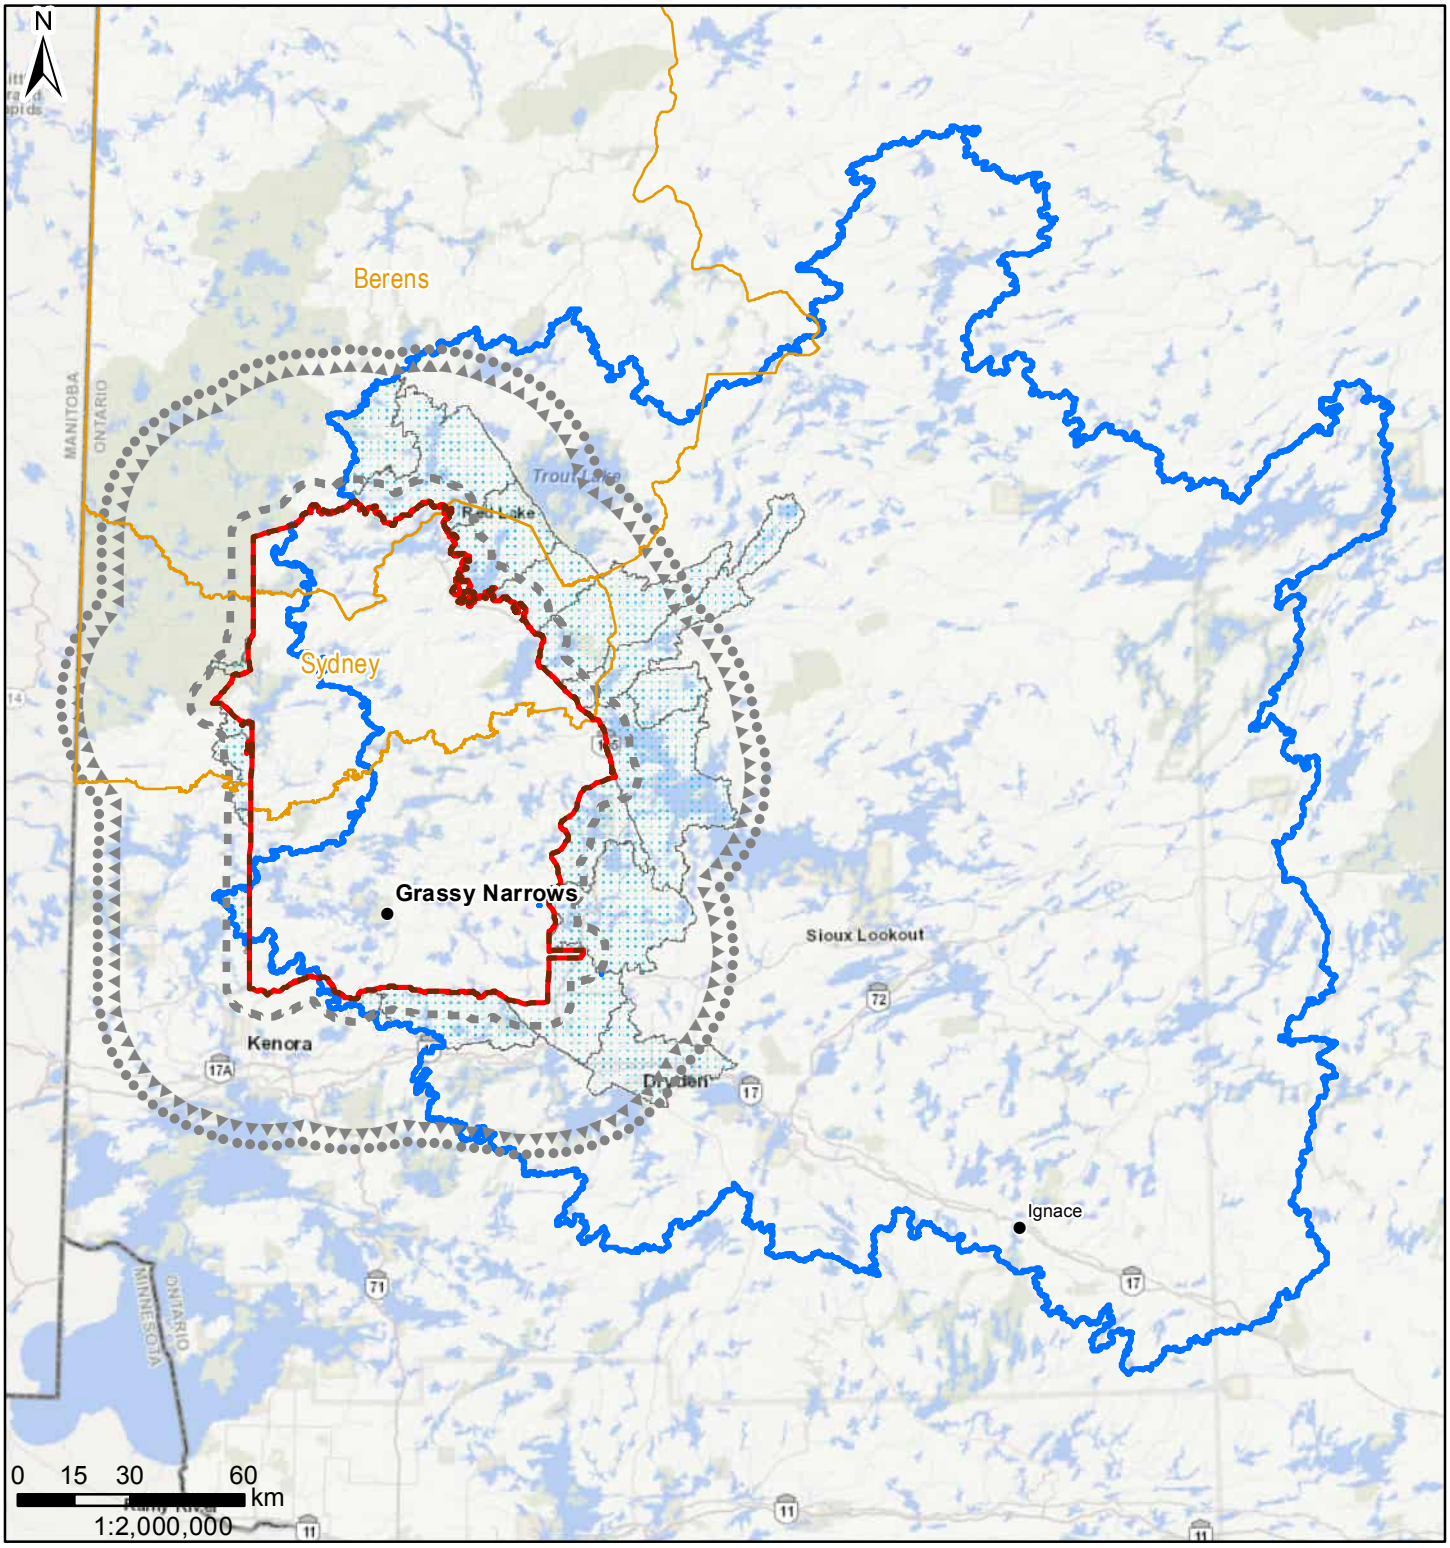
Map Date and Time: 2023-10-26 2:17:10 PM

Asubpeeschoseewagong (Grassy Narrows) Interim Core Area of Interest for Mining



- Interim Core Area of Interest for Mining
- Moose Home Range (6km)
- Wolverine Home Range Area (36km)
- Walleye Migration Area (40km)
- Caribou Range Boundaries
- Nearby Quaternary Watersheds That Flow Into The Core
- English River Watershed at Separation Narrows

N.B. This is an interim product created under duress arising from the escalation of imposed mining activity by the Crown and industry and for the sole purpose of identifying an interim area for negotiations on mining related activity. It is not a complete representation of Grassy Narrows' area of interest. Due to unique circumstances and capacity constraints Grassy Narrows has not completed comprehensive studies required to fully determine its area of interest including, but not limited to, land use and occupancy, ethnohistory, archeaology, biology, and hydrology. For example, rights and interests associated with air quality, migratory birds, travel routes, marten, lake sturgeon, wolves, eastern cougar, landscape intactness, climate resilience, biodiversity, genetic diversity, and many other factors are not reflected here. Also, linear boundaries are an imposed non-Indigenous concept that does not accord with the nature of Grassy Narrows' relationship with the land which includes extensive interconnectedness, reciprocity, travel, sharing, and trade. This map does not limit any claims by Grassy Narrows people to assert their rights and interests throughout their territory and to protect themselves from harm to their health, rights, way of life, livelihood, society, and environment. Grassy Narrows people have Treaty rights, and practice them, throughout the Treaty 3 area. Grassy Narrows people also have inalienable inherent rights given by the Creator, some of which are affirmed in international law and instruments. The Grassy Narrows people are the true experts about their land, rights, and interests.

April 10, 2025

Great Bear Resources Ltd.
25 York Street, 17th Floor
Toronto, ON. M5J 2V5

SENT VIA EMAIL: bruno.almeida@kinross.com; Crystal.McCullough@Kinross.com

Dear Bruno Almeida;

NOTICE

On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows First Nation" or "Grassy Narrows"), we write to inform you that you hold claims, leases, or other mining tenures within the Grassy Narrows Interim Core Area of Interest for Mining ("Core Area").

Area Subject to Grassy Narrows Interests

We are concerned that you and your associates at your company, Great Bear Resources Ltd. have staked or acquired claims, or tenures derived from them, within the Interim Core Area of Interest for Mining, and on our Territory. We are further concerned that you have made no attempt to contact our First Nation to inform us about your plans and intentions, staking activities, and any early exploration activities that you have carried out, and to hear what we have to say.

We have attached a map of our Core Area at two different scales. Please note that this interim map is not comprehensive and is subject to change.

Grassy Narrows has a longstanding connection to the claimed area dating back to the time of the Treaty and before. Our ancestors have practiced, and we currently continue to practice our Anishinaabe way of life; a way of life that relies on a healthy environment and is central to our identity, health, wellness, and livelihood. This area is part of the whole that forms the sacred landscape which gives us life and which we are in relationship within every aspect of our lives, hearts, spirits, and dreams.

Our community members exercise our Treaty rights in the claimed area through activities such as hunting, travel, camping, fishing, gathering medicines, and teaching their children the Anishinaabe way of life. Our community members boat, canoe, portage, and camp in the vicinity of the claimed area, and in the process, they hunt, fish, gather plants, and drink the water.

Your company's mining claims or tenure also fall within the range of wildlife such as moose, wolverine, and caribou that may travel within our Indigenous Protected and Conserved Area ("IPCA"). In addition, walleye within the area of your mining claims or tenure may also migrate to the IPCA. These are indicator species for a wide range of terrestrial and water-based creatures

that we use which spend part of their lives within the claimed area and would be impacted by mining activities. Birds that we use would also spend part of their lives within the claimed area.

We are on a healing journey, trying to recover from the extreme damage that colonization and attempted forced assimilation have done to our people, including through the imposition of Crown policy and regulatory schemes related to residential schools, dams, relocation, mercury contamination, child apprehension, industrial logging, and mining. Our environment, culture, society, economy, and health have been harmed. We need to allow the land to heal because healthy land will help to heal our people. This is what reconciliation means to Grassy Narrows. We have called on Ontario and on companies to stop pushing mining activity and industrial logging on us. We call on you and your associates at your company to let us protect our land so that we can heal our people.

We strongly urge you to reconsider your plans in our Core Area and to seize this opportunity to set a course for a future that is free of conflict over mining.

Area Subject to Cumulative Effects

For many generations the Crown has imposed harmful law and policy on us, including through the Indian Act, the banning of our ceremonies, residential schools, relocation, the 60s scoop, and the ongoing removal of our children from our community. These policies have caused grave harm to our people and impaired the exercise of our rights. They have undermined our strong society and way of life and have left us more vulnerable to the impacts of industry.

At the same time, Grassy Narrows people and our Territory have been subjected to a long series of industrial attacks which have been imposed on us against our will. These include the damming of our river, mercury pollution, industrial logging, and mining activity. Each of these industrial attacks have had grave impacts on their own which have been well documented. In addition, each of these industrial attacks has compounded the existing harm that remains from previous attacks, creating unbearable cumulative impacts, thereby prolonging and exacerbating our inter-generational crisis.

These extreme and compounding industrial impacts have been carried out by industry, and allowed by the Crown, without any serious consideration of their cumulative effects on Grassy Narrows and the exercise of Grassy Narrows' rights. We have raised clear concerns, since the 1970s at least, that our environment, rights, way of life, and our health were at or beyond the breaking point due to the impacts of industry on the resources on which we have heavily relied for our wellbeing, livelihood, and the viability of our community. We have repeatedly requested environmental assessments. To this day, with respect to our Territory, industry and the Crown have failed to conduct a collaborative Land use Plan; failed to complete a source water protection plan; failed to carry out an environmental assessment; and failed to undertake an assessment of cumulative effects.

Our river that gives us life remains poisoned.

Our walleye are unsafe to eat.

Our sturgeon are rare.

Our moose are scarce.

Our caribou are nearly extirpated.

Our pine marten habitat is depleted.

Our medicines are tainted.

Our sacred landscape is desecrated and scarred.

Our way of life is diminished.

Our people suffer from poverty, food insecurity, disease, and premature death.

Our Treaty rights are impaired, our health has been harmed, and we have been discriminated against.

The crisis that was created by mercury, damming, and relocation, and which has been exacerbated by industrial logging and mining activity, continues.

And yet your company has staked or acquired mining claims or tenure on our Territory. This risks taking us farther past the point of “reasonable,” “justifiable” impacts on Grassy Narrows’ rights, health, and way of life.

We are long past the time when the industry and the Crown should have listened to Grassy Narrows when we said enough is enough. We are decades past the time when industry and the Crown should have realized that the harm to Grassy Narrows was too much, and the Treaty promises were being dishonourably compromised by imposed industry allowed by the Crown. The Crown and industry can no longer impose further impacts on our land and our people when the cumulative impacts from past development mean that any further imposed industry will unjustifiably infringe our Treaty rights, harm our health, and discriminate against us.

We ask your company to open your heart and to respect Grassy Narrows.

Area Subject to Treaty Land Entitlement Claim

We would like to ensure that you are aware that Grassy Narrows has an active Treaty Land Entitlement (“TLE”) claim that has been accepted by the Crown and is under negotiation for resolution. Part of the resolution of the claim will include an addition to Grassy Narrows' reserve lands, and compensation for lost use. Grassy Narrows is currently engaged in a process to select its additional reserve lands. All of Grassy Narrows Territory is currently potential reserve lands additions under consideration.

The Crown has asserted that lands which have encumbrances, such as mining claims, will be more challenging to designate as additional reserve lands. This means that your mining claims and tenures adversely impact our ability to select reserve land additions and are an impediment to the successful resolution of our TLE claim.

Further, lands which have been impacted by mining exploration such as cutting lines, pitting, trenching, stripping, and drilling, decline in ecological health, experience a degradation of their intactness, and therefore become less suitable as additional reserve lands. Over the last few decades, vast parts of our Territory have been encumbered and degraded through industrial actions imposed on Grassy Narrows. This has severely restricted the available suitable

additional reserve lands.

Grassy Narrows has been clear that there should be no new encumbrances on our Territory, and no new degradation to our Territory, as this would unfairly further reduce the available suitable additional reserve lands (in addition to other impacts outlined elsewhere). This would impair the ability to correct the injustice that was done to us by having been denied a fairly sized reserve for over a century.

Area Subject to Litigation

Grassy Narrows has commenced two legal proceedings addressing Crown failures that have the potential to impact your company's mining interests in Grassy Narrows' Core Area.

First, on June 4, 2024, Grassy Narrows served Ontario and Canada with notice of our intention to sue for breach of Treaty obligations, fiduciary duties, and obligations arising from the Honour of the Crown by failing to protect Grassy Narrows Treaty rights, including from:

- The effects of mercury and other pollutants discharged by the pulp and paper mill in Dryden, Ontario, into the English and Wabigoon River System; and

- The cumulative impacts of industry and land use including mining activity.

Paragraph 95 of the Statement of Claim addresses the issue of the Crown's continued authorization of industrial activities that increase the mercury load, net methylation, bioavailability and biomagnification in the ecosystem.

Paragraph 102 outlines the cumulative impacts of industry and land use that have interfered with Grassy Narrows' Treaty rights, including contaminating air, land and water in and around the Area, degrading the land important to hunting, trapping, fishing and gathering, impacting wildlife habitat and populations, and interfering with the spiritual and cultural integrity of the Area and Grassy Narrows' relationship to it, among other things. Paragraph 103 addresses the harms caused by these cumulative impacts of industry and land use.

Your mining claims and other tenures continue the unlawful and harmful Crown conduct that is the subject of the lawsuit.

Secondly, on July 12, 2024, Grassy Narrows served a Notice of Application on Ontario asserting that the Mining Act regime violates section 35 of the *Constitution Act, 1982* by failing to consult, accommodate or obtain consent prior to registering mining claims within the Interim Core Area of Interest for Mining.

Grassy Narrows is seeking a declaration that mining claims registered pursuant to this unconstitutional regime and further mining tenures derived from those leases are invalid, which would include any claims, leases, and patents registered by your company in the Area. Ontario did not consult, accommodate nor obtain consent from Grassy Narrows prior to registering your company's mining claims, and the leases, patents and other mining tenures derived from them.

As relief, Grassy Narrows is seeking a declaration that "existing mining claims, including mining activities such assessment work and exploration activities, and third-party mining interests granted under the Mining Claim Grant Regime within the Area are not consistent with section 35 of the *Constitution Act, 1982* and UNDRIP and are of no force or effect."

If Grassy Narrows is successful in either or both of these legal proceedings, your company's mining claims and other tenures would potentially be impacted and could be invalidated.

Area Subject to Unmet Legal Duties

In 1978, Ontario and Canada signed a Memorandum of Understanding ("1978 MOU") with Grassy Narrows in which the Crown committed to resolve in good faith the impacts of mercury on the environment that Grassy Narrows people heavily relied upon for the viability of our community, and the related health, social, economic, cultural, and environmental impacts on the people of Grassy Narrows. It was agreed that the issues would be resolved through a combination of financial compensation and land, or control over land, and furthermore in a manner that would enhance Grassy Narrows' self-determination, self-sufficiency, and control over local affairs wherever possible.

Although some agreements were reached, there remain outstanding obligations on the Crown, including with respect to increasing Grassy Narrows control and self-determination over Grassy Narrows lands. From the outset of our discussions under the 1978 MOU, Grassy Narrows was clear that in order to recover from the impacts of mercury and other harms, we need Crown recognition of Grassy Narrows' ownership, control, and protection of our Territory which will allow Grassy Narrows to make decisions with respect to our Territory that support our way of life and our livelihood. In the 1970s, 1980s, and 1990s Ontario committed to negotiate increased Grassy Narrows control over our lands, in addition to providing meaningful compensation for our people. However, those negotiations and obligations remain unresolved.

The Crown and Grassy Narrows have a fiduciary relationship, and our Treaty rights attract fiduciary obligations. When the Crown seized functional management and control of our lands and water, including through use of force, in the time since the Crown and Grassy Narrows entered into a Treaty relationship, the Crown assumed a duty to Grassy Narrows when exercising that imposed control over our Indigenous interests including our pre-existing legal interests in exercising our fishing, hunting and trapping rights and other traditional practices, including our medicine gathering and wild-rice picking. Grassy Narrows has been at the mercy of the exercise of Ontario's imposed fiduciary decision-making over our Territory as Ontario unilaterally authorized industrial activity, and otherwise has made decisions that affect the land, water and other natural resources of our Territory which we rely on to exercise our rights, practice our way of life, and maintain our health.

Under imposed Crown management and discretionary control, the health of our Territory and our people have seriously declined, our way of life has been degraded, and the exercise of our Treaty rights has been impaired.

In the 1980s, and since, we called for a moratorium on industrial activity in our Territory until our negotiations with Ontario were concluded.

However, rather than honour this moratorium, the Treaty promises, and the 1978 MOU obligations, Ontario abandoned the negotiations in the mid-1990s and exercised its imposed control in a way that unleashed industry on our Territory to our detriment.

The Crown's dishonourable conduct and abandonment of its fiduciary obligations continue. And now instead of helping to set us on a path back to health, prosperity, and wellness, as promised, the Ministry has granted thousands of mining claims and approved numerous exploration

permits on our Territory. This conduct will compound the harms imposed on our people by further compromising our health and degrading our Territory and impairing and unreasonably limiting the exercise of our rights.

The failure of the Crown to uphold its honour and its fiduciary duty to us has the potential to impact the legitimacy of your claims and your ability to carry out mining exploration activity on them.

Grassy Narrows calls on your company to respect Grassy Narrows' law and rights

We call on Great Bear Resources Ltd. to respect Grassy Narrows' law and our inherent, Aboriginal, and Treaty rights, and to commit to comply with Grassy Narrows' rights and laws.

We call on your company to halt all staking and mineral exploration and mining related activities within the Interim Core Area of Interest for Mining and to confirm this halt in writing with us.

We call on your company to commit to gain our free, prior and informed consent before staking any claims, applying for any tenures, and carrying out any activities within the Interim Core Area of Interest for Mining.

We further call on your company to engage with us, and to gain our free, prior, and informed consent, for activities that are outside of our Core Area, but which may have upstream or downstream, downwind, migratory, or other off-site impacts on our Core Area and our people.

Request to meet to identify and resolve any conflicting third-party interests

If you insist on continuing to hold interests in and operate these claims or other mining tenures in our Core Area of Interest for Mining and that may impact our IPCA, despite the information shared with you in this correspondence – that such activity would be in violation of our ANA law, and our rights and interests and in an area with excessive existing cumulative impacts, that conflicts with our TLE process, and is subject to litigation – then we raise the following additional considerations which form a barrier to us meaningfully understanding your interest in our Core Area and engaging with you about these claims:

1) **Insufficient information:** You have yet to provide ANA with any information related to your past and planned activities with these claims. We have enclosed a list of questions at Appendix A for your company to complete with respect to your activities in our Core Area. Please provide detailed responses to allow ANA to better understand your activities and to prepare to evaluate them.

2) **Capacity funding:** The process of evaluating your activities and engaging with your company comes at an expense to ANA. We must hire staff, engage our community, and obtain professional support from experts, lawyers, and advisors to engage with you in a meaningful way. Our First Nation is even more impoverished than our First Nation peers due to the ongoing impacts of mercury poisoning. We lack the funds required to engage in an informed way. Please commit to funding ANA's reasonable costs of engaging with your company.

3) **Mercury Crisis:** Our territory has already experienced a great deal of harm from industrial activities including mercury, damming, and industrial logging. The cumulative effects of these industrial impacts have already passed the point of an unreasonable,

unjustifiable impact on the exercise of our Treaty rights, and on our health and wellbeing. As a result, our community suffers from unusually high rates of conditions including poverty, food insecurity, disease, neurological conditions, conditions affecting learning, and premature death. We cannot tolerate any further imposed impacts to our environment, our rights, our health, and our wellbeing. As well, the social conditions created by mercury poisoning and the cumulative impacts of industry place us in an ongoing crisis which make us unable to meaningfully engage on mining exploration. We require that the Crown resolve our ongoing crisis caused by mercury contamination and cumulative impacts before we can meaningfully engage about mining.

4) **Fundamental matters must be addressed:** For decades Grassy Narrows has been raising important matters with the Crown including mercury justice, self-determination, unmet obligations, Treaty rights, cumulative impacts, withdrawals, free entry, land use designations, and land protection. Grassy Narrows has invited Ontario to a table to find honourable resolutions to these matters. For years, Ontario has refused to even come to the table. Ontario continues to refuse to come to the table on the fundamental issues that require negotiation. The issues with these many mining claims and other tenures flow from larger upstream strategic issues which continue to fester because Ontario refuses to engage on them, but rather seeks to impose their unilateral will on Grassy Narrows. As the decades pass, it is Grassy Narrows people and our environment who suffer as a result. Ontario must deal honourably with Grassy Narrows by resolving in good faith these long-standing matters.

Grassy Narrows requests that you and your associates at your company meet with the Grassy Narrows Lands Protection Team, once the above barriers have been addressed, to identify and discuss any third-party interests you and your associates at your company may have in the Interim Core Area of Interest for Mining that conflict with Grassy Narrows' rights and interests.

In preparation for a meeting and to ensure it is constructive amongst the parties, Grassy Narrows requests that you and your associates at your company respond to this letter in writing to:

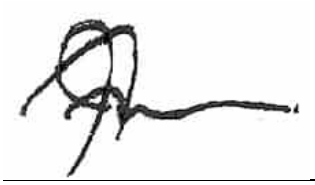
- Confirm your company's attendance at the corporate stakeholder meeting;
- Specify your company's representatives, and their positions, who will attend the meeting;
- Commit to respect the ANA Law and confirm your agreement not to pursue any mining-related activities within the Interim Core Area of Interest for Mining without ANA's free, prior, and informed consent;
- Commit that your company will work with Grassy Narrows in good faith to resolve any potentially conflicting third-party interests in the Interim Core Area of Interest for Mining;
- Specify with particulars any third-party interests you believe exist in the area proposed as the Interim Core Area of Interest for Mining with relation to your company's staked claims or tenures and any concerns which may need to be resolved, and your suggested resolution; and
- Respond to the questions that are listed in Appendix A.

Please respond within 90 days and address all correspondence to Joseph Fobister, Lead Negotiator for the Grassy Narrows Lands Protection Team. While copying ANA's Lands Protection Team, Mike Fobister, David Sone, Jackie Esmonde, Sydney Lang, Dan Mossip-Balkwill, and Annelies Cooper.

We look forward to meeting with you and your associates at your company.

Awsa,

Asubpeeschoseewagong Anishinabek (Grassy Narrows First Nation)



Joseph Fobister, Lead Negotiator for the Grassy Narrows Lands Protection Team.

APPENDIX A

INFORMATION REQUESTS

ANA has become aware that you and your associates at your company hold claims or other mining tenures and may be planning to carry out staking, exploration or mining related work in our area ("mining related activity"). Please provide the following information and answer the following questions in detail in order to allow ANA to understand and assess your activities.

1. Detail when and how your company, and any predecessors on these claims or tenures, have contacted Grassy Narrows and/or MINES with regards to any claim staking and exploration or mining related activity within our Interim Core Area and provide copies of all correspondence to date. Please also provide copies of any previous correspondence between your company, and its predecessors, and Grassy Narrows.

2. Please provide copies of any correspondence between your company and MINES about these claims or mining tenures.

3. Did MINES inform your company that these claims were on Grassy Narrows Territory and within the Grassy Narrows Interim Core Area?

4. Did MINES inform your company that Grassy Narrows has rights and interests in this Area and is concerned about claim staking, mining exploration, and mining activity in this Area?

5. If your claims or tenures were previously held by anybody else, please detail your and your company's relationship with any individuals or companies who previously owned these claims.

6. Do you or your company have an exploration plan or other mining related plans for these claims or tenures, and if so, please provide a copy.

7. Have you or your company or any predecessors, carried out any early exploration activity which does not require notice to MINES or MNRF? If so, please provide detailed information about this work?

8. Does your company have any existing plans, or plans under development, for mining related activity of any kind in, or near, our Interim Core Area, or which could impact the Interim Core Area? If so, please provide complete details. If not, will you commit to sharing with us any such plans, the moment they come under development, should such an instance arise?

9. Specify which mineral resource(s) is/are being explored or developed.

10. Specify the size of the workforce carrying out mining related activities. Provide small/medium scale maps (aerial photography or satellite imagery if possible) of the locality/region that is the subject of the claim staking and any planned mining related activity.

11. Provide a more detailed large-scale map showing location (at high resolution) identifying

where specific mineral exploration activity is to occur. This would identify which mineral claim and where within the mineral claim the planned worksite will be, or has been, and any relevant geographic features. Buffers should be built around the worksite locations to reflect post-permitting 'adjustment' of actual drill hole or access route.

12. Provide any surface geology or other thematic mapping that might suggest landforms important for wildlife distribution, Traditional Land Use, etc. (i.e. eskers, end moraines, outwash channels, glacial lake beds, rivers, lakes, streams, wetlands, portages, etc.).

13. Specify location and provide a detailed summary of any prior mining related activity in the proposed program area, including prior staking, permits and leases, and maps showing their locations.

14. If remediation from past activities is required, how will you remediate the site(s)? If remediation from past activities is not required, please provide documentation supporting this.

15. What is the nature of the proposed activity (e.g. early-stage prospecting, magnetic surveys, geotech auger sampling, shovel testing, diamond drilling, reciprocal drilling with water, bulk sampling, blasting of bedrock, trenching, etc.)? What is the anticipated physical impact of the activity? When will the activity take place? Where will the specific activity take place?

16. Detail the planned access to the proposed program and its location in relation to trails and winter roads in the area. Have or will any new access routes such as trails be created? What alternative access options have been identified, how were they assessed and why was the preferred option chosen?

17. How and when will the worksite be accessed? (e.g. chopper access, winter road logistics, walking rigs on trails prepared by bulldozer, etc.)

18. Has or will a camp site be constructed? Where? Please detail relevant logistics regarding the base camp and waste disposal.

19. Have or will camp materials be removed after the work? In detail, how will garbage, brush, sewage and overburden be dealt with? What kinds of fuel will be used, and how and where will the fuel be stored? How will the fuel be transferred, and what is the contingency plan in the event of a spill? Following the mining related activity, how will the site be cleaned up, reclaimed, or remediated?

20. Please detail the fuel dump management plan. Where are dumps to be located and what are the protocols for removal of barrels or containing spills? Detail whether stream crossings or travel close to lake shores will occur? In addition, detail overlay of proposed activity with hydrological features to understand proximity to lakes, wetlands, and river systems and identify which fish species use those water bodies, and whether any spawning areas or other special habitat areas exist in the area.

21. Detail strategies for protection from spills, ground disturbance, and enhanced erosion from preparing approaches.

22. Will the past or future work, including access, disturb soils in such a way that will

increase the release of mercury from those soils, or increase the net methylation of mercury within those soils? What assessment has been done and what evidence supports your position? What monitoring will be done to confirm this?

23. Specify the nature of site preparation for drilling or other activities (i.e. drill dropped in by chopper onto a log pad, or drill pad cleared and levelled by bulldozer).

24. Provide an overlay of the proposed activity with range maps of moose, wolverine, and caribou.

25. Provide an overlay of proposed activity with land classification details, with a special focus on the sub-range habitat features for moose, wolverine, and caribou (e.g. wintering areas, nursery areas and travel corridors, calving areas, denning areas).

26. Detail the source of all water to be used in the exploration program and their geographic locations. If drilling requires water, where will the water be drawn from; how will it be transported (pump and hose through bush, or hauled in water tanker behind vehicle and drawn along prepared trails); how much will be used, and how will waste water be disposed of?

27. Will the past or future work disturb waterways in such a way that will increase the release of mercury from those waterways, or increase the net methylation of mercury within those waterways or other impacts? What assessment has been done and what evidence supports your position? What monitoring will be done to confirm this?

28. Will any drilling fluids be used? If so, which? What are the procedures that will be used to ensure their safety including storage, use, recovery, removal, and spills?

29. Will any toxic substances be used in the work on present on site? If so, which? What are the procedures that will be used to ensure their safety including storage, use, recovery, removal, and spills?

30. What other authorizations (e.g. fisheries, permit to take water, other permits) are required for this project?

31. How will the mining-related activities change the water, air or land? What impacts will each of these changes have on land, water, fish, and wildlife?

32. Have or will your mining-related activities create any off-site impacts that will impact the Interim Core Area such as downstream or downwind impacts, impacts to migratory wildlife and fish, edge effects, etc.?

33. What will the cumulative impacts of your current and planned activities be and how does this contribute to the overall cumulative impacts of industry on Grassy Narrows Interim Core Area?

34. What First Nations Territories are included in the area of your mining-related activities?

35. What communication have you or your company had with MINES about Aboriginal and Treaty rights in relation to your mining-related? Please provide copies.

36. Has MINES delegated to you or your company any of the procedural (or other) aspects of the Crown's legal duty under Canadian law for consultation and meaningful accommodation with First Nations? If so, which? Please provide all relevant documentation.

37. What is your company's opinion on what ANA's inherent, Aboriginal and Treaty rights are on the area of your mining-related activities?

38. What is your company's opinion on what your responsibilities are with respect to ANA's inherent, Aboriginal, and Treaty rights in the area of your mining-related activities?

39. Does your company commit to abiding by the United Nations Declaration on the Rights of Indigenous Peoples?

40. Does your company commit to not carry out staking, mining exploration, and other mining related activities in the Interim Core Area of Interest for Mining unless ANA has given its free, prior, and informed consent?

41. Will your company fund ANA's reasonable costs of engaging with your company including the costs of ANA staff, community engagement, experts, legal counsel, and advisors?

42. Will your company fund ANA to commission an independent archaeological assessment of your activity areas including drill sites, access routes, camps, waste sites, etc.?

43. Does your company have a policy and an enforcement plan to prevent gender-based violence by your employees and contractors?

44. What is the total area (in ha) of your company's combined claims and leases in the Interim Core Area?

45. What is the total dollar value of the work that you and/or your company has, or any predecessors have, done on claims and leases in the Interim Core Area to date?

46. What is your and/or your company's appraisal of the market value of your combined claims and leases in the Interim Core Area?

47. Does your company commit to respecting the ANA Land Declaration and other ANA laws?

48. Do you and/or your company believe that you have any interests in the Interim Core Area? Please specify.

49. Do you and/or your company believe that any of your asserted interests may conflict with the Interim Core Area? Please specify how and provide reasons. Please also outline your company's proposed resolution.

50. Do you or your company have any other concerns which may need to be resolved with ANA? Please outline your suggested resolutions in detail.

51. Do you and/or your company commit to working with ANA in good faith to resolve any

potentially conflicting interests which you and/or your company believes you have in the Interim Core Area?

52. Will you and/or your company write a letter expressing support for ANA's Interim Core Area?

Attention: Aaron MacDonell (aaron.macdonell@kinross.com)
Kinross Gold Corp.

Dear Aaron MacDonell,

RE: Great Bear Gold Project – IA Process

I am writing on behalf of the Grassy Narrows First Nation's Land Protection Team with respect to the Impact Assessment for the Great Bear Gold Project.

Over the past few months, you have asked us to comment on and respond to your proposals in relation to various aspects of the Impact Statement that you are preparing. You have consistently requested that we provide comments within a short two-week time period and have denied our requests for additional time to respond.

Your timelines do not work for us.

We have informed you on multiple occassions that your timelines are insufficient and that we need more time to review your proposals, to assess their impacts, to engage with our community and our experts, to carry out our governance process, and to develop a response. Some of your questions require extensive research, archival work, and studies to answer. This kind of work typically takes years to complete. A few weeks is insufficient time in the best of circumstances.

As you know, our Territory has already experienced a great deal of harm from industrial activities. As a result, our community suffers from unusually high rates of conditions including poverty, food insecurity, disease, neurological conditions, conditions affecting learning, youth suicide, and premature death. The health and social conditions created by mercury poisoning and the cumulative impacts of industry place us in an ongoing crisis which is a barrier to our ability to meaningfully engage within your timelines.

We also need sufficient time to complete our own studies, including a land use and occupancy study, ethnohistorical report, baseline water and wildlife studies, social and economic impact studies, cumulative impacts assessments, and an ANA Indigenous Environmental Assessment, among other things. We have informed you of this requirement from the outset, and yet you have only recently provided capacity support, and only for a subset of these needs. We have begun work on that subset, but as noted

before, this work takes time.

Simply put, we need more time.

Grassy Narrows needs to be included in this process, but we need to be included in a good way.

For example, on March 3, 2025, you informed us that you had hired consultants to collect community-specific information from on-reserve service providers in Grassy Narrows. You gave us until March 21, 2025, only 14 business days, to provide you with this information. If we did not respond to you by March 10, 2025, you said that you would instruct your consultants to reach out to key service providers in Grassy Narrows on March 11, 2025 without us. You planned to move forward in this manner without our participation and/or consent to do so. We asked for more time and that you pause this work in the meantime. In response, you denied our request for more time and instead responded that the Impact Statement will proceed without this information.

The process that you proposed to collect data on the effects of the Project on on-reserve services was not a meaningful process and did not provide us with sufficient time to consider your proposal, let alone complete the work that you requested. The Impact Statement must include this information and we need to be included in this process. Grassy Narrows needs 180 days to prepare a submission with respect to the effects of the Project on the social conditions of Grassy Narrows, particularly with respect to on-reserve services. Grassy Narrows also needs 180 days to review the memo that you prepared with respect to the secondary sources of traditional knowledge and the sources therein. We also need substantial additional time to complete our preliminary Landuse and Occupancy study.

We have yet to receive any funding to complete baseline studies on water, fish, and wildlife. You have asked us to rely on baseline work done by others. But when our experts reviewed that work they found fundamental flaws, including the use of invalid lab methods, misleading reporting of data, insufficient duration of studies, and an absence of key parameters. Our experts concluded that your existing baseline data is inadequate, so we cannot rely on it.

On December 19, 2024, you shared with us a Mercury Study Plan with a short window for comments. As you know, mercury is a primary concern for us, and this Study Plan purports to be capable of determining whether your mine will have impacts on mercury and methylation. Our experts provided preliminary comments in which they identified fundamental flaws in your Mercury Study Plan. However, we have yet to hear any response from you. We have yet to receive an updated Mercury Study Plan that seeks to correct the fundamental flaws for our review. We also know that the IAAC plans to establish an independent Expert Technical Review group on methylation, but this group has yet to be established and so has not been able to review your Mercury Study Plan which is highly relevant to their mandate. We have yet to hear anything about how you propose to proceed.

We strongly urge you not to proceed with the fundamentally flawed Mercury Study Plan until:

a. You have corrected all of the flaws identified in our preliminary comments and our experts have verified this;
b. We have had time to complete a comprehensive review of the revised Study Plan and to identify any further concerns;
c. The IAAC Expert Technical Review group has reviewed the Study Plan and found it to be valid; and
d. We have given our consent for the Study Plan.

Your approach to engagement with respect to Phase 2 of the Impact Assessment process has been rushed, has not respected the context that we are working from and our repeated requests for more time, and has not been consistent with the spirit of reconciliation, the duty to consult, the standard of free, prior and informed consent, nor the *United Nations Declaration on the Rights of Indigenous People.*

We again call on Kinross to pause the process, and to provide us with sufficient time to meaningully engage and participate in the Impact Assessment process and to respect that we are a mercury poisoned community that is actively dealing with the mercury crisis and the cumulative impacts of industrial activities.

Please confirm in writing that you will respect our need for additional time to meaningfully engage and participate in all stages of the Impact Assessment process.

Dear Aaron MacDonell,

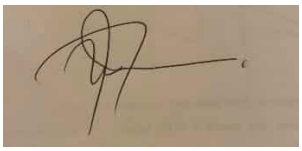
RE: Great Bear Gold Project – Update on Preliminary Land Use and Occupancy Study

I am writing to provide an update on the Preliminary Land Use and Occupancy Study. I have enclosed an update letter from Professor Anna Willow, the consultant anthropologist we have engaged to support Grassy Narrows in conducting this study.

As she notes in her letter, the community is working diligently on the study. Completing a full Land Use and Occupancy Study typically takes three to ten years to complete. In light of the unreasonable timelines imposed by the Impact Assessment process, the team is working to prepare a preliminary report. However, this is expected to require a further six to eight months.

It is important that the information in the pending Preliminary Report, and in future reports, inform decision making on this project so that Grassy Narrows' landuse can be taken into account. We urge you to ensure that the timelines and next steps for the Impact Assessment build in time for consideration of land use information. We urge you not to proceed with any work that could impact Grassy Narrows' landuse, including early and advanced exploration activities.

Miigwetch,



Joseph B. Fobister

To Whom It May Concern:

I am a consultant hired by Asubpeeschoseewagong Anishinabek (Grassy Narrows First Nation) to assist with their ongoing documentation of land use in the Grassy Narrows' Interim Core Area of Interest for Mining, particularly in the portions of the territory potentially impacted by the proposed Kinross Great Bear Mine. In particular, I am working with Grassy Narrows to prepare a Preliminary Land Use and Occupancy Study for the Great Bear Project.

In addition to my work with Asubpeeschoseewagong Anishinabek, I am a full Professor in the Ohio State University's Department of Anthropology with extensive expertise and publications in the areas of cultural and environmental anthropology, especially concerning Anishinabe land use and environmental relationships.

I am writing to report that the Asubpeeschoseewagong Anishinabek community is working diligently on the important process of land use documentation. Completing a full Land Use and Occupancy Study within a First Nations community typically takes between three and ten years. Knowing that the timeline imposed in this case is much shorter, we are doing all we can to collect and analyze data as expediently as possible to prepare a Preliminary Report. However, this report will likely take a further 6-8 months to prepare.

From the data already gathered, we can confidently report that the Grassy Narrows Interim Core Area of Interest for Mining in general, and the vicinity of the proposed Great Bear Mine in particular, was used by Asubpeeschoseewagong Anishinabek families in the past and continues to be used by members of the community for traditional subsistence and cultural practices (i.e., hunting, fishing, trapping, gathering, and travel) today. We have also documented community members' extensive concerns about potential water contamination as a result of proposed mining activity in that area.

More information will be provided as soon as it is available.

Cordially,

Anna J. Willow
Professor, Ohio State University

Re: Preliminary review of the Great Bear Project Mercury Plan, December 2024

1 Introduction

I have been asked to provide a preliminary review the Great Bear Project Mercury Study Plan (WSP, December 2024), and provide an Expert Opinion concerning the adequacy of the plan to protect receiving waters and biota from the direct and indirect effects of the proposed project. As there is little new information provided in this document, a substantial amount of this memo is derived from prior opinions and memos of mine that have reviewed other submissions from the Proponent. These are listed in materials referred.

2 Qualifications

I received my PhD in Geography from McGill University, Montreal, Canada in 1999 with a specialization in hydrology, mercury biogeochemistry, and wetland science. I was subsequently employed as a Professor at the University of Toronto Mississauga campus in Mississauga Ontario, Canada for 10 years, establishing an internationally recognized research program on hydrology and mercury in the environment. In 2010, I was recruited by the University of Western Ontario to the position of Professor and Canada Research Chair in Environment and Sustainability. I am considered an internationally recognized expert in the field of watershed biogeochemistry and the environmental cycling of mercury.

I have authored or co-authored over 100 peer-reviewed scientific papers and book chapters, and have made, or contributed to significant discoveries concerning the role of wetlands on the production and export of methylmercury (e.g. Branfireun et al., 1996; 1998; 1999; 2001; 2005; McCarter et al., 2017). I have been involved in high-impact state-of-the-science publications that have provided significant direction to the mercury research community (Harris et al., 2007; Munthe et al., 2007; Branfireun et al., 2020; Blanchfield et al., 2021). In addition to environmental biogeochemistry, research in my group has broadened to include the impacts of mercury on biota, including migratory birds (e.g. Ma et al., 2018a,b).

3 Summary of Opinions Concerning the Great Bear Project Mercury Study Plan

The Great Bear Project Mercury Study Plan provides a more comprehensive background discussion (Section 1.2) of mercury biogeochemistry than any previous document that I have reviewed from the project Proponent. In Prior submissions, the direct and indirect effects on mercury biogeochemistry of the proposed project have been dismissed, downplayed or ignored, so an increased acknowledgment of the link between sulphate loading from the proposed project from the Proponent is welcome. The presentation of the basics of mercury biogeochemistry is significantly more scientifically correct than the erroneous and misleading prior submissions from the Proponent indicating to me that there is effort being invested to coming up to speed about the current state-of-the-science mercury methylation, which I consider to be a central issue related to the proposed project. Indeed the Proponent acquiesces to the indisputable link between sulphate and mercury methylation, in contrast with the attempts to sew doubt found in prior submissions (Kinross Response to ANA Memo concerning

Great Bear Project AEX ECA Application, August 1, 2024), and goes so far as to acknowledge that arguments to apply site specific knowledge to setting mercury thresholds are valid. Despite this effort, there has surprisingly been no change in the interpretation of baseline data nor the proposed plan for effects monitoring for mercury or methylmercury – I find the same errors in a more attractive wrapper. The facts related to the inadequacy of the background data, sampling frequency, analytical methods, and misrepresentation of the receiving water body receiving effluent (Chukuni River) remain in this document, and evidence-based corrections in prior submissions by ANA have not been acknowledged or addressed, although many are now hidden by vague and over-generalized language. The only salient new information in the Mercury Study Plan is the Proponent's suggested application of a model (GoldSim) to predict changes in mercury and methylmercury as a result of the project. This model is a wholly inappropriate framework for this purpose and cannot provide the information that the Proponent suggests. As such, none of what is presented in this plan addresses the TISG requirement:

"Of particular note, the potential for project contributions to methylmercury production in downstream watersheds requires a detailed and robust analysis. The proponent must submit a study plan to the Agency with sufficient time to facilitate a review by experts and interested parties and to inform the studies undertaken. This includes establishing baseline methodology and effects assessment methodology related to methylmercury as outlined in section 8.6 Groundwater and Surface Water and 8.8 Fish and Fish Habitat."

This requirement is not met because none of the inadequacies of background data or future monitoring that have been previously identified have been addressed let alone acknowledged, and important information from prior documents was omitted which would permit a complete review by experts and interested parties who do not have full knowledge of what has been proposed in prior submissions from the Proponent. As many of these issues have been addressed in prior submissions from ANA, my opinions regarding the Great Bear Project Mercury Study Plan are reiterations of prior concerns with the exception of the discussion of the inappropriateness of GoldSim, which was informed by written and oral testimony that I presented for another case (and was supported by the US Environmental Protection Agency and Army Corps of Engineers).

It is my opinion that:

1) The selective reliance on achieving on and off site water quality that complies with water quality guidelines (CCME) inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota.

2) The background data collected as part of the baseline studies for this project are largely erroneous or their interpretation is flawed, rendering them neither comprehensive nor sufficient to detect whether the project will have measurable impacts on fish mercury levels in the future.

3) The assimilative capacity of the receiving waters (Chukuni River) as a mitigation strategy for excess sulphate loading is not supported by available data. As this is the only measure that has been proposed to address the indirect downstream effect of sulphate-related methylmercury production, there is no evidence that other adverse downstream effects can be avoided.

4) The model that the Proponent indicates will be used to predict changes in mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish (including assessment bioaccumulation / bio-magnification pathways) can technically deliver none of these outcomes.

4 Opinion 1: The selective reliance on achieving on and off site water quality that complies with water quality guidelines (CCME) in inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota.

Section 2.2.1 of the Great Bear Project Mercury Plan States the following:

> Existing baseline mercury and methylmercury concentrations in surface water and groundwater are compared against applicable guidelines for the protection of aquatic life as well as health-based drinking water quality guidelines, including the:
>
> −CCME guideline for total mercury for the protection of aquatic life (26 ng/L)
> −CCME guideline for methylmercury for the protection of aquatic life **(0.04 ng/L (sic)**
> −Canadian drinking water quality for mercury (1,000 ng/L)
> −United States Environmental Protection Agency (US EPA 1997) criterion of 0.05 ng/L for filtered methylmercury in water for the protection of fish-eating wildlife species

Disregarding the fact that the authors of the report surprisingly misstate the CCME guideline for methylmercury (it is 4 ng/L not 0.04, although 0.04 would be more scientifically justifiable), the statement that the data from the proposed project will be "compared against" any criteria is meaningless, because one may compare an apple to an orange; no intent, threshold, nor trigger value is indicated or even implied by this language. Despite quoting the more reasonable US EPA criterion of 0.05 ng/L methylmercury for the protection of fish-eating wildlife, prior documents submitted for this project indicate clearly that the Proponent intends (and has been approved by the Ontario MECP) to apply the CCME guideline the project from a compliance standpoint, so the reader should presume that the CCME values are the regulatory thresholds being applied by this Mercury Plan, rather than merely comparisons. As I have stated in prior opinions, there is no other way to characterize the CCME guideline values for mercury and methylmercury as anything but useless for the protection of fish consumers, and even if discharges or indirect effects were a fraction of these guideline limits there would be significant potential for downstream impairments of aquatic resources. For example, the CCME Criterion for (Total) mercury is 26 ng/L, which is a value (developed from a 1991 protocol) for the **direct** protection of aquatic life. Despite being profoundly outdated, the CCME document provides valuable commentary that is all too frequently ignored when setting regulatory criteria based on this single value, including "*The protocol **does not** address exposure through **food or bioaccumulation** to higher trophic levels*", and "*if the ultimate management objective for mercury is to protect high trophic level aquatic life and/or those wildlife that prey on aquatic life, **more stringent site-specific application** of these water quality guidelines may be necessary*" (CCME, 2003, p.2; **emphasis mine**).

Although the Province of Ontario is silent on the issue of any other water quality guidelines for mercury, other jurisdictions have been more engaged with revising their mercury and

methylmercury based on best available science at the time. British Columbia explicitly acknowledges the limitations of the CCMEs guidelines, stating "It should be noted that the CCME (2000) in developing guidelines for fresh and marine waters did not consider bioaccumulation effects per se, but based their guidelines on **chronic toxicity**. They caution that the guidelines that they have developed 'may not protect wildlife that consume aquatic life'." (British Columbia Ministry of Environment and Lands, 2001; emphasis mine). We may reasonably extend the statement about consumers of aquatic life to humans. Despite the document being nearly as old as the original CCME guidance, BC takes the interesting approach of defining the water quality guideline to protect wildlife for total mercury by scaling it as a function of the percentage of total mercury that is methylmercury, acknowledging that methylmercury is the only form of mercury that bioaccumulates and biomagnifies in wildlife. Their Table 5 indicates that only in environments where methylmercury is largely not being formed would the CCME guideline of 26 ng/L for total mercury be remotely reasonable for fish consumers to be protected. In environments where methylmercury makes up an increasing fraction of total mercury, the allowable amount of total mercury decreases proportionally with the %methylmercury in the system. At 8% of total mercury as methylmercury, the guideline for total mercury is 1.25 ng/L. Even at 8% methylmercury the BC guideline total mercury value is below the detection limit of the technique that the Proponent declares adequate for the purposes of monitoring (DL of ~ 5 ng/L). The Proponent states in this document (as I provided to them in prior submissions) that that % methylmercury in surface waters of the proposed project can exceed 14% (using their own sparse data), translating to a guideline concentration of a mere 0.72 ng/L for the protection of wildlife consuming aquatic life. Despite the BC document being nearly 25 years old, the rationale for their mercury criteria is logical, and recognize the fact that even low levels of mercury in the environment can bioaccumulate and biomagnify to hazardous levels for fish consumers if the landscape has high methylmercury production potential. It is clear that current conditions in surface waters in the project area already exceed this criteria, meaning that **any** cumulative effect would be in exceedance of BC criteria for mercury in freshwater.

I find it impossible to accept any generalized guideline for mercury or methylmercury in aquatic environments, and instead advise site specific assessment for appropriate threshold levels (which the CCME also explicitly does in their 2003 document, but never seems to be considered). An acceptance of this project mercury plan adhering to the CCME guidance for mercury and methylmercury threshold concentrations for direct and indirect effects is effectively a license to impair downstream resources given the low concentrations of mercury identified by the Proponent through limited baseline sampling. Site specific criterion for mercury and methylmercury must be required here, and derived from **appropriate** baseline data – scant little of which currently exist (see Opinion 2).

5 Opinion 2: The background data collected as part of the baseline studies for this project are largely erroneous or their interpretation is flawed, rendering them neither comprehensive nor sufficient to detect whether the project will have measurable impacts on fish mercury levels in the future.

In the context of the protection of fish consumers, nearly all of the background data for total mercury are useless and stated incorrectly. All of the "data" that are reported in Table 2.10 of "Attachment 4 - Surface and Groundwater Technical Supporting Document" (March 2024) for total mercury are not data at all, but the reporting detection limits of the contract laboratory.

The background mercury data in water (with the exception of the handful of appropriate trace mercury and methylmercury analyses that were conducted by Flett Research) **is incorrect**. The data provided for mercury **are not data** – they are detection limits of the inappropriate technique used to do element scans by inductively coupled plasma – mass spectrometry (ICP-MS). ICP-MS in a standard configuration cannot generate data for mercury with appropriate detection limits (despite the Proponent's assertion to the contrary in the Mercury Plan). Moreover, the Proponent treats these detection limit placeholders as data – **these are not data.** If the contract laboratory reported these values as data, then they are not operating in compliance with ISO 17025 protocols. If the Proponent substituted detection limits for samples reported to be below the detection limit by the contract lab, then this is not correct procedure and should be stated as such. In both cases, a serious lack of oversight and understanding of analytical results is clear as **these are not data**. There is also insufficient data for methylmercury in surface water as this critical parameter was only measured sparsely as part of the baseline monitoring program. As a result, there is virtually no background data for mercury in surface waters for the project area, nor is there sufficient monitoring in the proposed plan because the appropriate trace mercury and methylmercury monitoring is only proposed at select locations and at a frequency that is insufficient to detect change over time, and with highly inappropriate threshold levels that are orders of magnitude above the levels at which adverse effects will occur.

Further investigation into the baseline monitoring data provided in Attachment 4 of the AEX-ECA application which contains all of the background data cited by the Proponent in the Mercury Plan also reveals that the **concentrations reported for sulphate were also erroneous** up until May of 2023 when the Proponent either changed analytical methods or laboratories, or incorrect instrument operation was corrected. From 2021-06-03 to 2023-03-30, we find data that are reported with no precision (i.e. no decimal place) and spuriously range from values of 1 to 11. I know of no analytical technique that would report concentrations like this (we see similarly erroneous data for parameters such as Chloride, TSS, TDS). The clearest evidence to me that this data is no better than random is the value of 7 mg/l on 2022-12-15, followed by a value of 1 mg/L four days later on 2022-12-19. Given that there was no appreciable change in river flow over this time, **these data are erroneous and cannot be used**. There is similar randomness in other parameters. The fact that the average concentrations that are reported directly in the Appendix are substantially different for the three stations on the Chukuni River should have been the first indication that there was a data quality problem.

Notably, the data quality changes substantially in May 2023, with two decimal place precision and a much more realistic range of concentrations (4.18 – 6.30 mg/L). Other parameters also show this step change in data quality. There was obviously a change in technique or in the contract laboratory being used that was not documented, which is contrary to best practices at the very least.

Other variables reported are also suspect up until this date as many of the physical parameters (e.g. TDS, TSS) and nutrient data ($N0_2$), contain inexplicable values, change in quality, or are dropped completely (e.g. NO_3-$N0_4$-T). The failure to note and censor these erroneous data is inexplicable – to use them to calculate descriptive statistics is inexcusable. For these variables (including sulphate) there are only 8-9 usable data points for all of the stations reported (including the Chukuni River).

The Mercury Plan makes reference to comprehensive background data about mercury and sulphate that will inform modelling efforts and trigger undefined actions should they change. One cannot numerically model concentrations of "below the detection limit". The reality is that the background data is neither "comprehensive" nor "sufficient" by any reasonable definition, and the approval of a Mercury Plan such as this is license to both proceed blind with respect to the site specific mercury conditions, as well as condone the continued use of an inappropriate analytical approach (despite the Proponent's statement to the contrary) that will reliably generate non-data that cannot capture trends in mercury concentrations across most of the sampling sites in the project area.

6 **Opinion 3: The assimilative capacity of the receiving waters (Chukuni River) as a mitigation strategy for excess sulphate loading is not supported by available data. As this is the only measure that has been proposed to address the indirect downstream effect of sulphate-related methylmercury production, there is no evidence that other adverse downstream effects can be avoided.**

Similar to the comparison to various mercury guidelines discussed above, the Proponent outlines in the Mercury Plan a range of sulphate mitigation measures that are being "considered" to address the issue of sulphate loading to sites of mercury methylation (Section 3.3). The primary mitigation measure outlined is to not discharge sulphate directly into sites with high methylation potential (e.g. wetlands). I am not sure that this constitutes a mitigation measure because of the obvious environmental consequence of doing so. Other measures being "considered" include various tailings management strategies and management of sulphate-bearing runoff. In the middle of the list is the **only** option that has been discussed and justified by the Proponent in all prior submissions:

"Discharging treated effluent to a large receiving watercourse (Chukuni River) that has a high oxygenation level and high assimilative capacity."

This 'mitigation strategy' has been commented on by myself and other experts in prior submissions, however this single sentence contains so much misleading information that it is worth breaking down here, making reference to the much more detailed discussion found in prior expert submissions.

1) **Treated effluent:** Indeed the Proponent has outlined strategies for treating effluent to be discharged to the Chukuni River, however none of the treatment technologies proposed target sulphate at all. Sulphate production from overburden and waste rock could be substantially greater than the Proponent states. Given that groundwater contributes nearly 80% of the total water outflows, 25% of groundwater samples (75^{th} percentile) from many locations in the project area had sulphate concentrations well in excess of 10 mg/L (Appendix B, Table 3 AEX-ECA Application), and the water treatment technology outlined by the Proponent has no capacity to remove sulphate, it would seem that the Proponent's 'expected' case of 10 mg/L sulphate is not just unlikely, but nearly impossible to achieve without even considering the potential for additional sulphate sources due to operations. Indeed without any additional treatment the Proponents 'extreme' case is likely a gross underestimate. With only gypsum saturation ultimately controlling sulphate solubility, sulphate concentrations in the range of 1000-1500 mg/L may be expected and are in fact, typical of many mine sites with oxidizing sulphide minerals like pyrite.

2) **Large watercourse:** This is of course a relative statement however a 20-year median annual discharge of 26.5 m^3/s is objectively a substantial flow. However as I have outlined in prior memos (Branfireun Review of Kinross Response to ANA Memo concerning Great Bear Project AEX ECA Application, August 1, 2024; October 7, 2024), median or mean statistics do not tell the whole story about assimilative capacity, despite the Proponent utilizing the simple numerical average of the entire daily discharge record (which upward biases the value) for all of their dilution scenarios presented in prior submissions to justify assimilative capacity. In the context of dilution of an environmentally relevant chemical, it is more relevant and protective to explore the lower ranges of flow, since it is at these levels that the river has less assimilative capacity and adverse effects are more likely. The 20-year average 25th percentile value is 14.2 m^3/s, meaning that for a full quarter of the year (which would include the relevant summer low flows when biogeochemical activity including methylation would be the highest), flows in the river are equal to or less than this value. The 20-year average minimum flows are only 5.7 m^3/s; more than 5 times lower than the discharge value that the Proponent used to calculate dilution. I argue that this is a more appropriate 'extreme' case discharge value to use, however it is notable that **the record contains a period of zero flow conditions in 2011 – a condition under which effluent discharge would make up 100% of river flow and would be completely undiluted (i.e. the river has zero assimilative capacity)**. 2023 was among the lowest flow years in the last 20, and the central tendency of the river discharge over that period is toward lower, and less variable flow. If the 2023 flow statistics (median, 25th percentile, and minimum flows of 13.5, 6.6 and 3.1 m^3/s are reflective of future drier conditions driven by climate change, then the use of a single value of average flow that is 10x greater than this low flow condition to calculate effluent dilution and demonstrate assimilative capacity is clearly not protective by any definition.

3) **High oxygenation level:** The Proponent has frequently made the argument that oxygenated waters in the receiving reach of the Chukuni River preclude negative effects of sulphate addition because sulphate reduction would not occur. This statement is misleading, as I could visit the most methylmercury contaminated lake in Ontario (Clay Lake) in August, measure surface water oxygen levels and declare it oxygenated. This would be ignoring the anoxic bottom waters and sediments where very high levels of methylmercury are formed. Of course, rivers do not stratify but it is well documented that they can have anaerobic sediments, biofilms and hyporheic zones where sulphate reduction and methylation can occur (despite having a well-mixed water column above). The biogeochemical status of the immediate receiving river reach is actually not the biggest issue here, it is the methylation potential of downstream waters where this well-oxygenated river will deliver sulphate that may be many times in excess of background levels.

Pakwash Lake is the first lake downstream of the proposed effluent discharge, and already has **five** fish species that have restricted consumption advisories due to mercury contamination (https://www.ontario.ca/page/fish-consumption-report?id=50459330) indicating that any further loading of methylmercury, or enhancement of the methylating process either in the lake or upstream would amplify an existing environmental degradation.

Whether the fish species with tissue mercury exceedances in Pakwash Lake immediately downstream of the proposed operation derive their methylmercury from Chukuni riverbank wetlands, river littoral sediments, biofilms or periphyton, anoxic profundal lake sediments, or anoxic hypolimnetic waters during stratification is actually irrelevant – methylmercury is produced in the aquatic environment because it is found in fish in downstream receiving waters

and it is dependent on the activity of sulphate-reducing bacteria, which are dependent on available sulphate. To have that many species with mercury consumption advisories confirms that this is a mercury sensitive environment with high mercury methylation potential.

4) **High assimilative capacity:** The argument was been made that additional sulphate might not enhance methylation in the receiving reach because it is oxygenated, but the Proponent has further argued that the proposed operation will not measurably increase sulphate in the Chukuni River and downstream receiving waters because of the dilution of the operation's effluent by the large flows of the Chakuni River (where dilution is used synonymously with assimilative capacity). All of the above points outline how the Proponent has arrived at the conclusion of high assimilative capacity through the application of erroneous/incorrect data, inappropriate analyses of river flows, and untested estimates of sulphate loading from project effluent, none of which is bounded by uncertainty. I have numerically laid out the potentially dire sulphate concentrations that may arise as a result of low flows combined with higher than stated effluent sulphate concentrations/volumes, should the reader choose to explore this more fully (Branfireun Review of Kinross Response to ANA Memo concerning Great Bear Project AEX ECA Application, August 1, 2024; October 7, 2024).

7 Opinion 4: The model that the proponent indicates will be used to predict changes in mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish (including assessment of bioaccumulation / bio-magnification pathways) cannot technically deliver any of these outcomes.

In the Great Bear Project Mercury Plan Section 3.4.3, the Proponent states that the GoldSim software modelling package will be used to "stimulate ***(sic)*** the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project." Without substantiation, they go on to state that "GoldSim has been extensively and successfully applied to simulate complex water resource management, mining operation, contaminant transport, and waste management projects and represents a robust industry-standard modelling software." Although I do not disagree that GoldSim has been widely applied to various industry problems I cannot speak to its success. I can say that it does not appear to ever have been applied to an environmental mercury speciation scenario. There is a clear reason for this – GoldSim is fundamentally (even with its CT submodel) a non-reactive mass-balance model that cannot incorporate mechanistic sorption/desorption reactions along flowpaths, the biomethylation process, nor the complex interaction between mercury and sulphate. As such, the model proposed can never be successfully applied in the manner that is proposed. A mass balance model *cannot* by definition incorporate mechanistically the input and removal processes for mercury, and *cannot* address the biogeochemical aspects of mercury methylation across the landscape which are at the root of the potential impacts associated with the Great Bear proposal. The reason why mass balance models are used for solutes (and can work for solutes that are conservative in water) is because they are simple to apply quickly and require little parameterization (i.e. are inexpensive to implement). Indeed they can have value to evaluate simple "what if" scenarios. However, being cheaper and easier to use is not sufficient justification for taking a naïve approach to evaluating possible environmental risks in a region of extreme mercury sensitivity, when much more defensible approaches exist, including models for watershed-steam mercury dynamics. On page 17 of the Mercury Plan, the authors state that GoldSim is used because it provides "a clear description and rationale for model input parameters and assumptions." I have seen this language used in other cases that I have opined about, with the implication being that GoldSim is somehow MORE clear in its description and

rationale of input parameters and assumptions than other models (i.e. superior). This seems to be popular but baseless justification, as it implies that it is somehow more transparent than other model frameworks.

The statement that the mass balance models like GoldSim are transparent with respect to data inputs is true, in that it is true that *any* model is transparent with respect to data inputs because one must know what the data inputs are in order to run the model (a non sequitur). What is also true of any model is the adage of "garbage in, garbage out." The definition of input parameters and stated variables is always required in any model, as is the establishment of boundary conditions and mechanisms that reflect the best available science. In the case of the Great Bear Project, we have a virtual absence of useable data for baseline water quality (see above), which means that we are at a loss for values for the very input parameters that are required.

The Great Bear Project Mercury Plan reaches even farther by stating that "Results of GoldSim modelling for surface water and sediment quality, described above, will be used to forecast and assess potential effects on fish mercury concentrations in downstream watersheds. Both small and large-bodied fish will be considered in this assessment." My understanding of GoldSim is that it uses the sediment compartment to model water chemistry, not the other way around, so to suggest that GoldSim can be used predictably for the sediment compartment is unrealistic beyond simple mass transfer, despite the importance of the sediment compartment for net methylation. More problematic is the leap of faith between whatever output is provided by GoldSim and a prediction of methylmercury concentrations in biota. There is no evidence of any such effort being successfully reported in the public domain; if the Proponent has advanced the science in this area then I would welcome an opportunity to review their efforts in this regard as it would mark a major breakthrough in modelling mercury biogeochemistry and biotic uptake. I suspect that this is not the case, since the means by which this is to be accomplished is apparently "changes in fish body burden mercury concentrations is considered to be the forecasted methylmercury concentration in the water column, as determined by the water quality model." I am not sure who "considered" this relationship, however it was not someone with a modest scientific understanding of the controls on fish tissue MeHg concentrations – such a simplistic forecasting relationship does not exist, and this is in addition to the fact that GoldSim cannot predict methylmercury concentrations in the first place.

8 Other Errors, Omissions and Concluding Remarks

There are other problematic statements throughout the Mercury Plan that are used to downplay the potential impacts of the project do not align with scientific facts. The statement "For example, SRB-induced mercury methylation could occur in areas of organic soils peripheral to the rock stockpiles; however, methylmercury production beneath rock stockpiles can be limited by low temperatures at the base of the stockpiles which will inhibit SRB activity." is patently false given that the SRB can be quite active at temperatures just above freezing (e.g. Fortin et al., 2000).

We have all kinds of details on sample handling and Quality Assurance/Quality Control procedures in Section 2.2.1 that convey attention to detail and rigour, however a statement about sampling frequency is carefully worded so that the inadequacy of the water quality sampling is not apparent.

Baseline surface water quality sampling generally occurs monthly to characterize seasonal variability in water quality, providing flow is present and that the monitoring site can be safely accessed. (GBP Mercury Plan, p.5)

This statement fails to identify which solutes will be measured from this 'generally' monthly sampling, however in prior documents, the Proponent has clearly indicated that low detection level mercury and methylmercury sampling will only be done at only **half of the sampling sites**, and are only to be taken **quarterly (4 times per year)**. This low frequency of sampling of the only mercury data of utility is insufficient to statistically detect change until that change is so substantial that its effects would be irreversible. Since all of the other mercury sampling will be subject to an inappropriate analytical technique that will mostly return non-detects, the proposed monitoring programs are effectively designed to avoid change detection and I expanded on this in a prior memo (Branfireun to Esmonde, on Advanced Exploration Program (AEX) Environmental Compliance Approval - Industrial Sewage Works (ECA – ISW) July 5, 2024).

Here, we see the assembly of a house of cards by the Proponent. We have a water quality model that is not capable of predicting mercury biogeochemical processes, and that is dependent on background data and proposed monitoring that is insufficient. The outcome will be the inevitable future conclusion by the Proponent that the combination has led to an inability to adequately predict changes in methylmercury concentrations in fish because of 'uncertainties' in GoldSim output, and 'unforeseen complexities' in coupling abiotic and biotic compartments. The reality is that these uncertainties and complexities are completely foreseeable as outlined here. The consideration of the December 2024 Mercury Plan as anything other than deficient will excuse the Proponent's future failure to predict the impact of the proposed development from a mercury perspective because of the appearance of due diligence at this stage of the process. I conclude that the TISG's requirement that the Proponent provide *a detailed and robust analysis on the potential for project contributions to methylmercury production in downstream watersheds* has not been met based on the information provided in their Mercury Plan.

Water Quality

Ambient Water Quality Guidelines for Mercury

Overview Report — First Update

Prepared pursuant to Section 2(e) of the
Environment Management Act, 1981

Original signed by Margaret Eckenfelder
Assistant Deputy Minister
Environment and Lands HQ Division
February, 2001

Summary

This report is one in a series that establishes ambient water quality guidelines for British Columbia. The guidelines are safe conditions or levels of contaminants, applicable province-wide, which are set to protect various water uses.

This report updates the 1989 BC Environment guidelines for total mercury (THg) by providing revised water quality guidelines to protect aquatic life from chronic effects of mercury. This was deemed to be necessary since the Canadian Council of Ministers of the Environment (CCME) have recently developed guidelines for mercury in the water column to protect aquatic life and in the flesh of aquatic life to protect wildlife. The report also outlines water quality guidelines to protect avian wildlife feeding on aquatic organisms. The updated guidelines are consistent with the CCME tissue residue guideline to protect wildlife from methyl mercury (MeHg) in their diet. The guidelines for livestock, irrigation and recreation, are unchanged from in the 1989 report. The guidelines are summarized in Table 1, Table 2, and Table 3.

Table 1: Summary of Water Quality Guidelines for Mercury

Water Use	30-d av. Conc.* (µg/L THg)	Maximum Conc. (µg/L THg)
Source Drinking Water	See Source Drinking Water Quality Guidelines: https://www2.gov.bc.ca/assets/download/1F11ABD2CBD24EB09A70B89AB50CE6B0	
Wildlife and Aquatic Life (Freshwater Estuarine and Marine)+ When MeHg = 0.5% of THg When MeHg = 1.0% of THg When MeHg = 8.0% of THg	 0.02 0.01 0.00125	None proposed
Irrigation Water Supplies	None proposed	2.0
Livestock Water	None proposed	3.0

* The 30-day average is based on five weekly samples taken in a period of 30 days.
+ If natural levels exceed the guidelines for aquatic life, then any increase allowed above the natural levels should be based on site-specific data.

Table 2: Tissue Residue Guidelines to Protect Wildlife from Mercury Toxicity

The concentration of methyl Hg in fish or shellfish consumed by wildlife should not exceed 0.033 µg/g wet weight.

Preface

THE MINISTRY OF ENVIRONMENT, LANDS AND PARKS (now called Ministry of Water, Land and Air Protection) develops province-wide ambient water quality guidelines for variables that are important in the surface waters of British Columbia. This work has the following goals:

1. to provide guidelines for the evaluation of data on water, sediment, and biota

The definition of a guideline is:

A maximum and/or a minimum value for a physical, chemical or biological characteristic of water, sediment or biota, which should not be exceeded to prevent specified detrimental effects from occurring to a water use, including aquatic life, under specified environmental conditions.

The guidelines are province-wide in application, are use-specific, and are developed for some or all of the following specific water uses:

- Raw drinking and public water supply
- Aquatic life
- Wildlife
- Agriculture (livestock watering and irrigation)
- Recreation and aesthetics

The guidelines are set after considering the scientific literature, guidelines from other jurisdictions, and general conditions in British Columbia. The scientific literature gives information on the effects of toxicants on various life forms. This information is not always conclusive because it is usually based on laboratory work which, at best, only approximates actual field conditions. To compensate for this uncertainty, guidelines have built-in safety factors which are conservative but reflect natural background conditions in the province.

Guidelines are subject to review and revision as new information becomes available, or as other circumstances dictate.

The guidelines apply to the ambient raw water source before it is diverted or treated for domestic use.

The Ministry of Health regulates the quality of water for domestic use after it is treated and delivered by a water purveyor.

Guidelines relating to public health at bathing beaches are the same as those used by the Ministry of Health which regulates the recreation and aesthetic use.

Introduction

Mercury is a non-essential element for plants and animals. However, metallic mercury is widely used in industry for the manufacture of chemicals, electrical equipment, power generation, dental amalgams and metallurgical gold. The mercurial compounds have found applications in paints, drywall compounds, scientific supplies, pharmaceuticals, fungicides and bactricides.

Mercury is found naturally in the earth crust, rocks, minerals, and coal and base metal deposits. Areas of high mercury content associated with zones of instability and volcanic and thermal activity have been found over the globe.

Many natural and anthropogenic sources contribute to environmental mercury loading. In the environment, mercury can exist in both organic and inorganic forms. Methyl mercury (MeHg), the most toxic form of mercury, tends to bioaccumulate and biomagnify in the aquatic food chain. Piscivorous mammals, fish and birds accumulate most of their body burden through diet.

Mercury is known to damage renal, nervous, reproductive, and developmental systems. The chemical form of mercury and route of entry are important determinants of its toxicity. Ingestion of inorganic mercury is primarily responsible for erosion of intestinal tracts and kidney damage in both animals and humans. Methyl mercury and short-chain organic mercurials destroy neuronal cells in areas of central nervous systems concerned with sensory and co-ordination functions.

In British Columbia, economic grade deposits of mercury are commonly associated with sedimentary rocks such as limestone and sandstone of the Palaezoic to Recent age. The province's richest mercury deposits are in the Pinchi Lake fault zone which extends from Fort St. James northwest to the Omineca River. Other major areas of mercury mineralization in British Columbia include Kamloops Lake, Bridge River, and Yalakom River.

The concentration of mercury in natural waters is generally low. However, elevated concentrations of mercury have been reported in British Columbia in areas contaminated by the industrial activity (e.g., Squamish) and where extensive mercury mineralization has occurred.

Historical mercury concentrations should be viewed with caution. Results from cleaner laboratory analytical methods with lower detection limits show that background mercury concentrations are lower than previously thought. Older high values may be the artifacts of high detection limits and artificial contamination during measurement.

Recommended Guidelines

Table 1 summarizes all guideline values including those that have been updated. This was deemed to be necessary since the Canadian Council of Ministers of the Environment (CCME) have recently developed guidelines for mercury in the water column to protect aquatic life and in the flesh of aquatic life to protect wildlife. There is obviously a need to reconcile all these guideline values in one document for the benefit of resource managers.

1. SOURCE DRINKING WATER

See the Source Drinking Water Quality Guidelines: Guideline Summary Document

https://www2.gov.bc.ca/assets/download/1F11ABD2CBD24EB09A70B89AB50CE6B0

2. AQUATIC LIFE (FRESHWATER, ESTUARINE AND MARINE)

These guidelines replace the 1989 BC Environment guidelines for fresh, marine and estuarine waters.

(a) The 30-day average guidelines for marine, estuarine and fresh waters are the same, due to the facts that:

- the bioaccumulation potential of mercury in marine and freshwater food chain is similar; and
- both are based on the 1999 CCME recommended tissue residue guideline to protect the most sensitive consumers of aquatic life (e.g., avian species).

The average concentration of total mercury in water as measured over a 30-day period (based on five weekly samples) should not exceed 0.02 ug/L when the methyl mercury (MeHg) constitutes less than or equal to 0.5% of the total mercury concentration. When the proportion of MeHg is greater than 0.5%, the guideline should be adjusted as indicated in the Table 3 below. The rationale for the graduated guideline is the fact that MeHg concentrations may vary in the environment. For example if the percent of MeHg is 11% the guideline would be calculated by the following equation:

0.1ng MeHg/L (WQGwl *see below in rationale section*) ÷ 0.11 (i.e. the % MeHg)
= 0.9 (guideline ng/L total Hg)

Table 3: The Total Hg Guideline as a Function of the Percentage of Methyl Mercury

% MeHg (of total Hg)	Guideline (ng/L total Hg)
0.5	20.0 ng/L
1.0	10.0 ng/L
2.5	4.0 ng/L
5.0	2.0 ng/L

These levels will protect freshwater aquatic life from chronic effects of mercury. They will also prevent undesirable accumulation of mercury from water to the food chain that may harm the most sensitive consumers (e.g., avian species) of aquatic life.

Rationale:

The following assumptions were made to update the 30-day average guideline to protect from mercury bioaccumulation in fish to a level that may harm wildlife consuming the mercury-contaminated fish:

All mercury in fish tissue is in the methylated form. This conclusion is consistent with observations made by researchers in the literature.

The MeHg bioaccumulation factor at a higher trophic level (level 3 or fish consumed by avian species) is 320,000 on wet-weight (BAF_{3ww}) basis or 1,600,000 on dry-weight (BAF_{3dw}) basis. This BAF is consistent with the US EPA recommended value and values observed in Squamish, British Columbia.

Based on recommended level of methyl mercury at 33 µg/kg wet-weight (diet) and the methyl mercury BAF_{3ww} of 320,000, the acceptable concentration in water for the protection of wildlife consuming fish can be estimated as follows:

$$WQGwl = (33\ \mu g\ MeHg\ kg^{-1} \times 1000\ mg/\mu g) / 320{,}000 = 0.1\ ng\ MeHg/L$$

(where WQGwl is the water quality guideline to protect wildlife)

Table 5 below expresses WQGwl in terms of the comparable THg levels for various percentages of MeHg as a function of THg.

Table 5. WQGwl In Terms of the Comparable THg Levels for Various Percentages of MeHg as a Function of THg

% MeHg (of total Hg)	WQGwl (ng/L total Hg)
0.5	20.0 ng/L
1.0	10.0 ng/L
2.5	4.0 ng/L
8.0	1.25 ng/L

This analysis suggests that the 1989 BC Environment's 30-day average guideline of 0.02 mg/L (or 20 ng/L) total mercury is valid as long as MeHg is less than or equal to 0.5% of the total mercury concentration. Appropriate water quality guidelines for MeHg concentrations other than those specified in the above table can be determined using a linear relationship between WQGwl and MeHg (%).

It should be noted that the CCME (2000) in developing guidelines for fresh and marine waters did not consider bioaccumulation effects per se, but based their guidelines on chronic toxicity. They caution that the guidelines that they have developed 'may not protect wildlife that consume aquatic life'. As well, they considered marine and fresh waters separately, even though there is no reason to suspect that the chemistry of each affects mercury or its bioaccumulation in fish and avian wildlife and do not provide a guideline for MeHg in marine water.

(b) The 1989 BC Environment guidelines for a maximum mercury concentration in either fresh or marine waters has been deleted due to the bioaccumulative nature of mercury which is the most important consideration in developing guidelines. Direct toxic effects that a maximum concentration is meant to protect against are seldom encountered and will be accounted for in bioaccumulation in most cases.

3. WILDLIFE

The 30-day average concentration of total mercury in water to protect wildlife should not exceed levels shown in Section 2 above. These guidelines are based on the tissue residue guideline recommended by the CCME (2000), and will protect the most sensitive avian life feeding on aquatic organisms that may accumulate undesirable levels of mercury in their tissues. This guideline replaces the 1989 BC Environment guideline of 3.0 mg THg/L that had been based on livestock sensitivity to mercury since there were insufficient data on mercury toxicity to avian wildlife. The CCME (2000) did not recommend mercury guidelines for wildlife.

Additionally, the methyl mercury concentration should not exceed 0.033 µg/g wet weight in the diet of wildlife. This guideline is consistent with the CCME (2000) tissue guidelines to protect avian wildlife feeding on fish and shellfish containing mercury.

4. LIVESTOCK WATER SUPPLY

The concentration of total mercury in livestock water supply should not exceed 3.0 µg/L at any time. This is consistent with the 1989 BC Environment and the CCME (1999) guidelines.

5. IRRIGATION

The maximum concentration of total mercury in irrigation water should not exceed 2.0 µg/L. This is consistent with the 1989 BC Environment guideline. The CCME (1999) did not recommend mercury guidelines for water used for irrigation.

Application of the Guidelines

1. FORMS OF MERCURY

Toxicity of mercury has been expressed in terms of both total and methyl forms of mercury. However, total mercury is recommended for setting water quality objectives for a given waterbody. The advantages of expressing toxicity on the basis of total mercury concentrations are:

i. all the mercury that may potentially be toxic is included in the measurement; if the total mercury concentration in water is within the guideline limits, then it is safe to conclude that no mercury pollution exists;
ii. for comparison purposes, there is a considerable amount of historical information available for total mercury; and
iii. total mercury measurements are routine and relatively inexpensive.

Mercury in aquatic organisms (e.g., fish) is predominantly in the methyl form and should also be measured when investigating mercury contamination problems in aquatic systems. The CCME recommended tissue residue guideline (0.033 micrograms MeHg/g wet weight-diet) should apply to protect wildlife consumers of fish.

The main disadvantage of using total mercury to assess water quality is that a large fraction of mercury may become biologically unavailable by forming complexes with the organic and suspended solids fractions of water. Nevertheless, given favourable environmental conditions, mercury complexed in such a manner will be released into the environment in readily available forms, becoming part of the food chain.

2. ASSESSMENT OF EXISTING WATER QUALITY

The guidelines recommended in this document are primarily based on laboratory bioassays that usually are performed with soluble forms of mercury under controlled conditions. Aquatic organisms in a natural environment, however, obtain their mercury burden from both water and food. Mercury from sediments

could become available to the organisms under certain environmental conditions. Thus measuring total mercury in water alone cannot be taken as a true measure of a mercury problem in a given waterbody.

Other assessment techniques include measurements of mercury in fish, and long-term bioassays with resident species using local water. The guidelines for mercury in fish can be used for to assess existing water quality. Long-term bioassays are complex and costly, and should be used for waterbodies with high fisheries values that are threatened by a controllable source.

The role of sulfate-reducing bacteria (SRB) in the cycling of Fe and S was studied in a young constructed wetland located in Kanata, Ontario, Canada. The wetland is a surface-flow system composed of three consecutive cells. Sediments and water samples were collected over the course of 1 year within each cell. Sediments were analyzed for the presence of SRB (using a lactate-rich medium), whereas surface and porewaters were analyzed for their concentrations of dissolved Fe and sulfate and for pH, E_h*, and dissolved organic carbon. Lactate-using SRB were present at all three sites within the wetland, and the populations were largest (*10^{10} *colony-forming units per gram of sediment) during the cold winter months, where the temperature of the water was ~1° C. The presence of high-SRB populations also corresponded to highly anoxic conditions within the sediments and to a decrease of sulfate concentrations, suggesting that cold temperature did not affect the activity of SRB. Our results indicate that Fe and S cycling in the young constructed wetland was active throughout the year, especially in the cold winter months, where large SRB populations were encountered. This suggests that Fe removal in wetlands can be effective in temperate climates, even though the temperature of the water decreases drastically during the winter.*

Keywords constructed wetland, iron cycling, sulfate-reducing bacteria, sulfur cycling

Biogeochemical reactions responsible for metal removal in constructed wetlands include adsorption onto reactive mineral and organic surfaces and precipitation as insoluble metal

Received 10 December 1999; accepted 3 April 2000.

We thank the city of Kanata, Ontario, Canada, for allowing us to sample the wetland. The project was supported by the University of Ottawa Research Fund and the Interfaculty Collaborative Research Fund. We also thank F.R. Pick and two anonymous reviewers for their constructive comments and suggestions.

oxides and sulfides (Tarutis and Unz 1996). Of all these processes, microbial sulfate reduction and the subsequent precipitation of metal sulfides have been identified as important reactions in metal removal in wetlands (Machemer and Wildeman 1992; Feng and Hsieh 1998; Webb et al. 1998). In fact, in many low-temperature sedimentary environments, microbial sulfate reduction is the sole mechanism responsible for the formation of iron monosulfides and pyrite (Berner 1984). Recent work has shown that such iron sulfide minerals play an important role in trace metal adsorption in anoxic sediments (Huerta-Diaz et al. 1998).

Microbial sulfate reduction depends on various physicochemical factors, including the supply of sulfates, the amount and type of organic electron donors, pH, and temperature (Berner 1984). In freshwater environments, such as wetlands, sulfate reduction rates are generally limited by the amount of sulfate, because the average SO_4 concentrations are ~50 to 450 μM (Feng and Hsieh 1998). In constructed wetlands, however, sulfate concentrations can be greater because of wastewater loading and anthropogenic activities. A second important factor influencing sulfate reduction in natural aqueous environments is temperature. Temperature effects on the growth of and reduction rates by sulfate-reducing bacteria (SRB) have been studied in sediments in cold climates, such as the Arctic and Antarctic (Isaksen and Jorgensen 1996; Sageman et al. 1998). The latter showed that SRB from Arctic sediments grew well at very low temperatures, but the sulfate reduction rates were greatest at much higher temperatures. The same studies concluded that sulfate reduction rates were more dependent on substrate supply than on temperature.

There is much concern about metal retention by constructed wetlands in northern climates (Maehlum et al. 1995; Reddy and Burgoon 1996). As surface water temperature decreases, microbial sulfate reduction rates are believed to decrease, perhaps leading to a decrease in metal retention. Data on the effect of temperature on SRB growth and sulfate reduction rates in wetlands are, however, limited. Batal (1989) hypothesized that SRB increase their numbers in cold water because the decrease in their metabolic rate provides more substrate for growth of other SRB. Therefore, metal retention, especially Fe, during the winter should be sustained because the increasing number of SRB should maintain the sulfate reduction rates.

The present study was initiated to examine the impact of seasonal variations of SRB populations on the cycling of Fe and SO_4 in the sediments of a young constructed wetland built to treat municipal and agricultural runoff. Seasonal variations in SRB numbers were expected to affect the removal of soluble Fe from the water.

Materials and Methods

Site Description

The Monahan wetland, located in the city of Kanata, Ontario, Canada, is a surface-flow system that was built in 1995 to control the quantity and quality of storm water runoff. The wetland is referred to as a young wetland because it has yet to accumulate a substantial amount of organic matter in its sediments. In young wetlands, the retention of metals depends more on adsorption onto organic matter than on microbial sulfate reduction observed in older wetlands (Machemer and Wildeman 1992). The Monahan wetland was designed to keep water velocities <0.5 m/s and to hold 35,000 m^3 of water. The mean water depth is 1.5 m and the total drainage basin area of the wetland is ~637 ha. The wetland itself has three consecutive cells, which were lined initially with a thick layer of clay to prevent water infiltration into the underlying aquifer. No organic substrate was added on the clay liner. The Monahan wetland is mainly colonized by cattails (*Typha latifolia*) (Table 1). Phosphorus loading to the Monahan wetland is relatively high (0.17 mg/L), which results in an intense

TABLE 1 Characteristics of the sampling sites

[b]The standard deviation ($n = 3$) is given in parentheses.

colonization of the littoral zones by cattails. As a result, ~44,000 kg of organic matter accumulate, mainly as peat, at the bottom of the wetland each year.

Downloaded by [University of Ottawa] at 10:48 12 November 2015

Sampling

Sediments and porewater samples were taken in each cell (at locations called sites 1, 2, and 3) of the wetland (Table 1). Sediments were collected in October and December 1997 and in April and August 1998. One sediment core was taken at each sampling date and site with a 10-cm-diameter plexiglass tube and was sectioned on site into 1-cm intervals. To avoid contamination, samples used for bacterial enumeration were taken in the middle of the core and stored in sterile glass vials. To minimize air contact, the vials were completely filled with sediments and stored on ice until their return to the laboratory. Most probable number (MPN) enumeration was carried out within 24 h of sampling. In situ measurements of pH and redox were also performed on the same sediment cores, using a portable pH meter. The pH electrode was calibrated on site with pH standards (at pH 4 and 7). The redox electrode was also calibrated on site with the ZoBell's solution (Nordstrom 1977). A second set of samples was taken in October 1997 for analysis of geochemical fractions. The sediments were placed in acid-washed bottles and kept at 4°C until being freeze-dried. Fresh surface sediments (from 0–2 cm deep) were also analyzed for organic matter content, as determined by loss on ignition.

Porewater samples (peepers) were collected in December 1997 and in April and August 1998 with plexiglass peepers. One peeper was installed per site and sampling date. Porewater peepers were filled with degassed ultrapure water and closed with a 0.2-μm pore-size filtering membrane (HT-Tufryn; Gelman Scientific). Peepers were inserted vertically into the sediments (not more than 0.5 m from the sediment cores) and left in place for 2 weeks (Carignan 1984). The peepers allowed for the collection of interstitial and surface waters at 1-cm-intervals along a 35-cm profile. Water samples were retrieved with 5-ml plastic syringes and transferred into preacidified plastic bottles (10 μl of conc. HCl for 4 ml of sample). Water sample collection was completed within 1 h of the retrieval of the peepers. The temperature of the overlying waters was also monitored on a monthly basis over the course of the sampling period. Surface water samples were collected every 3 days from April 1997 to October 1997 at site 1 (inflow) and site 3 (outflow). Samples were filtered (with 0.45-μm pore-size filter) and acidified after collection and analyzed for dissolved organic carbon (DOC) by using a DC-190 (Hewlett Packard) TOC analyzer.

MPN Counts of SRB

Numbers of viable SRB were estimated with MPN dilutions in liquid medium (American Public Health Association, 1965) within 24 h of sampling. A modified version of Postgate's

growth medium B (Postgate 1984; 10 g/L Bacto-Tryptone [Difco], 5.9 ml 60% Na-lactate, 2 g/L $MgSO_4 \cdot 7H_2O$, 0.5 g/L Fe $SO_4 \cdot 7H_2O$, and 0.5 g/L Na_2SO_3) was used along with a reducing agent supplement (RAS; 7.5 g/L ascorbic acid and 7.5 ml/L thioglycollic acid). All solutions were adjusted to pH 7.50 with 2 M NaOH. Dilution series (1:10) were carried out in culture tubes, starting with ~1 g of wet sample in 9 ml of reduced water (100 ml/L RAS and 2.1 g/L NaCl adjusted to pH 7.50 with 2 M NaOH). Between each dilution, the tubes were vortex-mixed for 1 min to thoroughly disperse the bacteria and sediments. Five tubes containing 9 ml of growth medium and 1 ml of RAS were then individually inoculated with 1 ml from each dilution set. Sealed tubes were left in the dark at room temperature until black Fe-sulfide precipitates started to form (~1–2 weeks). Note that the medium used might have preferentially selected lactate-utilizing SRB over nonlactate users.

Sequential Chemical Extraction

Sediments were subjected to a sequential chemical extraction to separate them into three iron-rich fractions: Fe-reactive, including oxides, carbonates, monosulfides, and hydrous aluminosilicates; Fe-silicates; and Fe-pyrite (Huerta-Diaz et al. 1993). Freeze-dried sediments (0.25 g) were first digested with 1 M HCl (10 ml) for 16 h. Iron concentration in the HCl fraction is referred to as Fe-reactive. The solid residue was then placed in 10 M HF (30 ml) for 16 h to extract Fe from silicate minerals, and finally any remaining residue was transferred to concentrated HNO_3 (10 ml) for 2 h to assess the pyrite fraction. All extractions were run on duplicate samples.

Iron and Sulfate Analysis

Sulfate concentrations in the porewater samples were analyzed by ion chromatography (Dionex DX-100) with a detection limit of 20 μM. Iron concentrations were measured by graphite furnace atomic absorption spectroscopy (Varian Spectra AA-250 plus), with a detection limit of 0.09 μM. Blanks and certified standards (SCP Science Canada) were used to ascertain the accuracy of the porewater Fe and SO_4 measurements. The iron content of each extraction fraction was analyzed by flame atomic absorption (Varian AA-1475) with use of appropriate standards and matrices; the detection limit of that method for Fe was 1.7 μM.

Statistical Analyses

Statistical analyses were performed with Systat 7.0 for Windows 95. Spatial and temporal differences in DOC content in surface water were tested by using a two-way parametric analysis of variances (ANOVA). Assumptions of the parametric ANOVA were tested with Wilkes–Shapiro test for normality of residuals, with Levene's test for homoscedasticity and with autocorrelation plots for independence among residuals.

Results

SRB Populations

Temperatures of surface water dropped near the freezing point in the winter, and a thin layer of ice (5–15 cm) developed over most of the wetland (Figure 1). Nevertheless, SRB were observed at all three sampling sites during each of the sampling periods (Figure 2), being recovered from the first 10 cm of sediment (organic and inorganic sedimentary material and clays from the liner material put at the bottom of the wetland during its construction). SRB

Downloaded by [University of Ottawa] at 10:48 12 November 2015

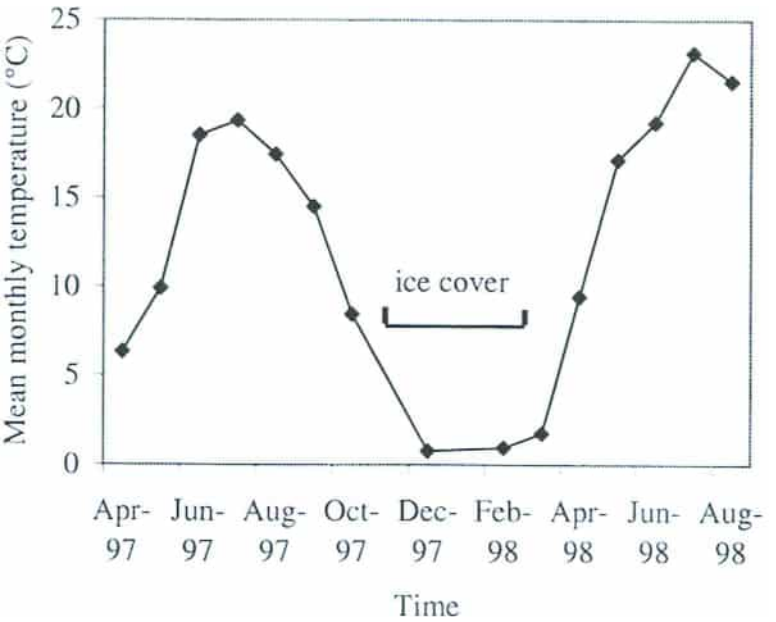

FIGURE 1 Average monthly temperature (°C) of the surface waters in the constructed wetland for the period April 1997 to August 1998.

Downloaded by [University of Ottawa] at 10:48 12 November 2015

populations varied with depth at all sites but appeared to fluctuate most as a function of the season, especially near the sediment–water interface. In fact, the largest SRB populations were encountered at site 1 during the winter sampling in December. The smallest SRB populations were seen in the upper layer of sediments at sites 1 and 2 in April.

Surface and Porewater Chemistry

The pH of interstitial waters was between 7.00 and 8.50 (Figure 3) and remained fairly stable with respect to both depth and sampling time. A slight pH increase was observed near the sediment–water interface at site 1 in August, at site 2 in October and April, and at site 3 at all sampling dates. On the other hand, redox conditions varied greatly with depth and sampling time (Figure 3). Although anoxic conditions prevailed in the sediment deeper than 1–2 cm, slightly oxic conditions were encountered near the sediment–water interface at site 1 in April and August, whereas the sediments were anoxic in October. At site 2, suboxic conditions prevailed near the surface in October and April, whereas the surface sediments were slightly anoxic in August. At site 3, conditions were suboxic to oxic near the surface in October and April, whereas the sediments were completely anoxic in August. Samples were not analyzed for pH and E_h in December.

One set of data for iron and sulfate is missing for site 3 in December, because the peeper could not be recovered from under the ice. At all sites and sampling times, Fe was not detected in the overlying waters, except at sites 1 and 2 in December, which had low concentrations of Fe (Figure 4). For all sites, Fe concentrations increased drastically near or at the sediment–water interface, especially at site 1 in April, at site 2 in December, and at site 3 in April (Figure 4). In addition, large fluctuations were observed within the sediments, especially in the deeper portion of the profiles, where sedimentary particles were mixed with clays. Sulfate concentrations showed a very different trend: Concentrations were greatest in the overlying waters and decreased sharply in the sediments (Figure 5). Sulfate

concentrations never exceeded 300 μmol/L below the sediment–water interface and did not vary much as a function of time. On the other hand, seasonal variations were observed in the overlying waters at all sites (Figure 5). The largest SO_4 concentrations were encountered in December at sites 1 and 2, were less in April, and reached a minimum in August.

DOC concentrations in the surface waters varied on temporal and spatial scales (Table 2). DOC concentrations ranged from 5.96 to 12.04 mg/L and differed significantly between seasons (Table 3). Throughout the year, basis, DOC concentrations at the inlet were significantly lower than at the outlet. The same difference in DOC concentrations between the inlet and outlet also occurred at each sampling date. DOC concentrations were particularly high in June 97, reaching 9.50 and 12.04 mg/L at the inlet and outlet, respectively.

Sediment Chemistry

The organic matter content of the surface sediments varied slightly between the three sampling sites (Table 1), with slightly higher values at sites 2 (middle cell) and 3 (outflow) than at

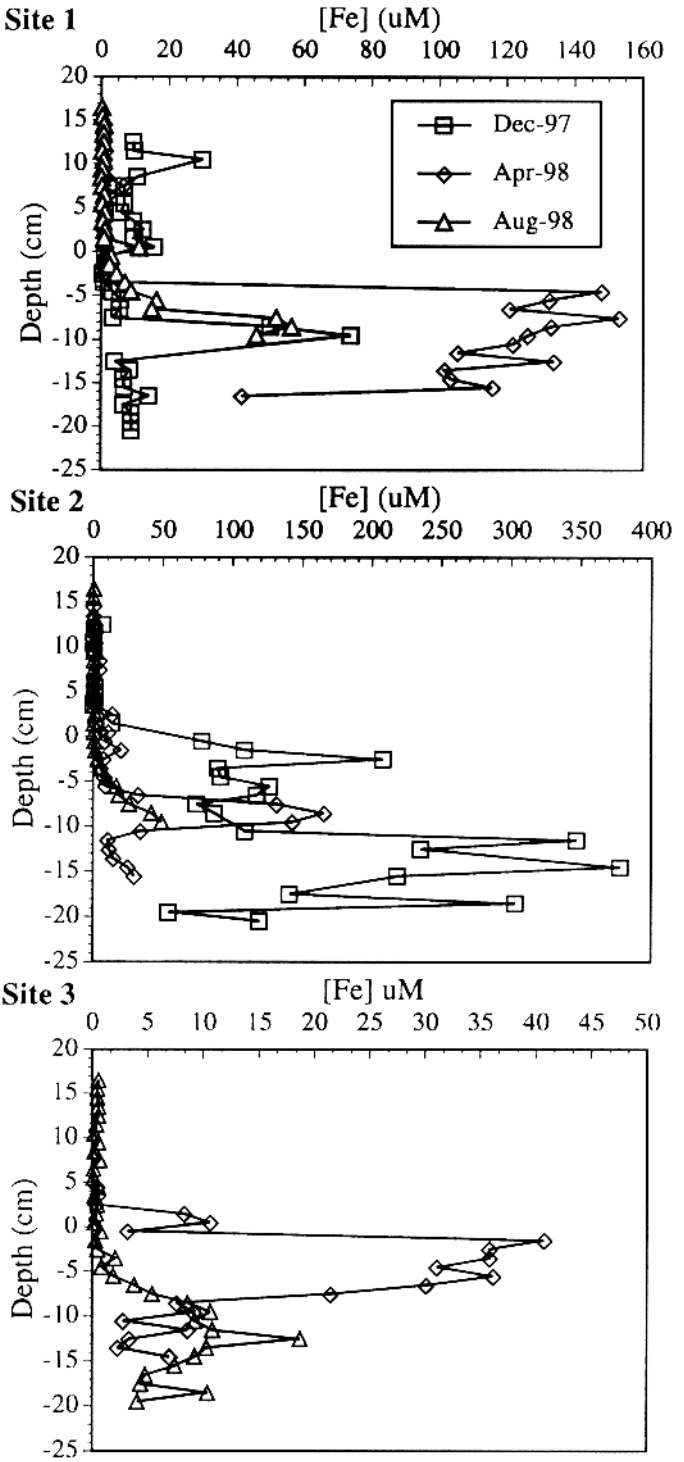

FIGURE 4 Fe concentration profiles in the overlying waters and in the porewaters for three sampling dates at site 1 (near the water inflow), site 2 (the middle cell), and site 3 (the outflow basin). Note the presence of dissolved Fe in the overlying waters at sites 1 and 2 in December.

site 1 (inflow). The reactive iron fraction showed a slight increase near the sediment–water interface at all three sites, whereas the silicate fraction fluctuated with depth (Figure 6). Fe concentrations associated with the pyrite fraction were less than those observed in the Fe-reactive and silicate fractions. In fact, no Fe was detected in the pyrite fraction at site 3.

Discussion

Fe and S Cycling and Redox Fluctuations

The cycling of iron and sulfur in wetlands and other aquatic environments is affected by redox reactions, which are triggered by the mineralization of organic matter (Stumm and Sulzberger 1992). In fact, the rapid consumption of oxygen during the degradation of organic matter and the subsequent use of alternate electron acceptors can move the oxic/anoxic barrier toward the sediment–water interface and create anoxic conditions in the surficial sediments (Froelich et al. 1979). Such redox fluctuations were observed in the sediments of the Monahan wetland throughout the year, especially in the top 2 cm of the sediments (Figure 3), in which completely anoxic conditions were encountered in October at site 1 and in August at site 3. Redox measurements were not made in December, but the presence of reducing conditions in the surface sediments and in the overlying waters of sites 1 and 2 was inferred by the presence of soluble Fe above the sediment–water interface (Figure 4). Under reducing conditions, Fe-rich minerals such as Fe-oxides undergo reductive dissolution,

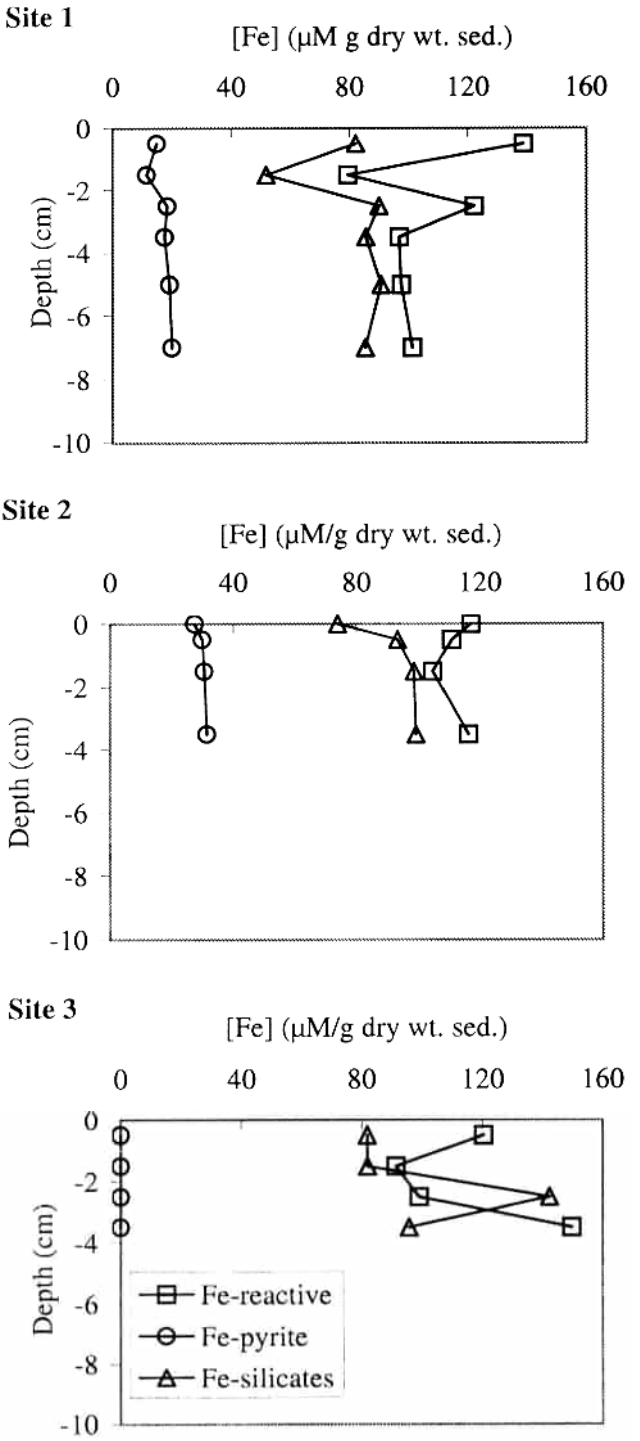

FIGURE 6 Profiles of Fe-rich fractions in the sediments of sites 1, 2, and 3 in October 1997 as determined by sequential chemical extraction. Fe-reactive was extracted with HCl, Fe-silicate with HF, and Fe-pyrite with HNO_3. Notice the absence of Fe-pyrite in the sediments of site 3.

which allows Fe(II) to either diffuse upward into the overlying waters or downward into the sediments (Stumm and Sulzberger 1992). The presence of an ice cover over most of the wetland during the winter months might have also contributed to the presence of anoxic conditions by limiting oxygen diffusion into the water. Redox fluctuations, however, were not constant within the wetland. For example, site 3 (outflow) often behaved differently from site 1 (inflow), and surface sediments near the inflow tended to be less oxic overall than the sediments at sites 2 and 3, even though they contained less organic material in the sediments and in the water at site 1 (Tables 1 and 2). These cell differences were probably caused by various degrees of oxygen consumption and differences in microbial activity throughout the year.

Sulfate concentration profiles in the Monahan wetland indicate that sulfate was reduced near the sediment–water interface (Figure 5), as indicated by the sharp decrease of concentrations in the sediments. Sulfate reduction was observed over the course of the year and did not appear to be limited to warmer months. In fact, sulfate concentrations within the sediments remained constant, whereas concentrations in the overlying waters increased during the winter months—probably because of the use of de-icing agents containing sulfate salts or sulfate impurities on the surrounding roads (Shanley 1994).

Microbial Sulfate Reduction

The decrease of sulfate concentrations showed a positive correlation with the presence of SRB in the sediments (Figures 2 and 5). SRB were indeed recovered throughout the year and did not appear to be greatly affected by the presence of suboxic conditions in the surface sediments or by the temperature. SRB were generally present in the surface sediments where oxic conditions prevailed, except at sites 1 and 2 in April 1998, where they were absent (Figure 2). This suggests that SRB were either oxygen-tolerant or living in anoxic microenvironments within the oxic sediments. Oxygen usually inhibits microbial sulfate reduction (Widdel 1988), but sulfate reducers have been isolated from oxic to suboxic environments (Canfield and DesMarais 1991; Sass et al. 1997). Visual observation of the wetland surface sediments revealed the presence of small black patches rich in Fe-sulfides within the oxic sediments, indicating the presence of microenvironments. On the other hand, the absence of SRB in the surface sediments at sites 1 and 2 in April and their presence at site 3 suggest possible changes in population dynamics.

Our results also indicate that SRB thrived during the colder months. In fact, the largest populations were encountered in December, when the temperature of the water was ~1°C (Figure 2). The largest SRB populations also corresponded to the largest decline of sulfate concentrations (Figure 5), suggesting an apparent increase in sulfate reduction during the colder months. Our results are surprising, because sulfate reduction rates in natural aquatic environments usually decrease during colder months (Abdollahi and Nedwell 1979; Moeslund et al. 1994; Holmer and Kristensen 1996). However, recent work by Sageman et al. (1998) and Isaksen and Jorgensen (1996) showed that optimum growth temperature for SRB isolated from cold environments was often higher than the in situ temperature, but the sulfate reduction rates were comparable with those measured in sediments of temperate climates. Numerous studies have also suggested that cold temperature might not inhibit bacterial life but might diminish the affinity of the bacteria for substrates (Wiebe et al. 1992; Nedwell and Rutter 1994; Isaksen and Jorgensen 1996; Sageman et al. 1998). It is difficult to conclude from our results that substrate affinity was a key factor in SRB growth at cold temperature, because we did not identify the various types of SRB and organic substrates in the water. In fact, it is possible that the growth medium used for the enumeration (MPN) preferentially selected lactate-utilizing SRB, which might not be representative of the whole SRB population in the wetland. Regarding substrate availability,

our limited number of DOC values (Table 2) suggest that the pool of organic substrates varied throughout the year from one site to the other, being generally lower in the winter because of low primary productivity (Mann and Wetzel 1995). Our results indicate that to compensate for the low organic content of the sediments and the potential lower affinity for the substrates, SRB increased in number during the colder months, which had the effect of maintaining the sulfate reduction rates throughout the year. Clearly more work is needed on the characterization and availability of potential organic donors to assess the role of substrate affinity.

SRB and Fe-Rich Mineral Formation

The dynamics of SRB populations and their effect on sulfur and iron cycling affected the mineralogy of the wetland sediments. The constructed wetland was 2 years old at the time of sampling and originally contained clay material at the bottom. Results from the chemical extraction (Figure 6) indicated that the surface sediments were enriched in reactive Fe, indicating that Fe was bound to carbonates, oxides, monosulfides, and hydrous aluminosilicates (Huerta-Diaz et al. 1993). In most natural aquatic environments, the enrichment of Fe-reactive compounds corresponds to the formation of diagenetic Fe-oxides and Fe-monosulfides (FeS). Diagenetic Fe-oxides usually form when soluble Fe(II) from anoxic sediments diffuses upward toward the oxic–anoxic interface and is oxidized to Fe(III) (Fortin et al. 1993), whereas Fe-monosulfides precipitate as a result of sulfide production during microbial sulfate reduction (Berner 1984). Seasonal variations in Fe and S cycling are therefore responsible for the enrichment in reactive Fe in the constructed wetland. On the other hand, the Fe-silicate fraction showed no distinctive patterns but simply reflected the existence of the clay material emplaced during construction of the wetland and its redistribution through bioturbation. In fact, visual observation of the sediment cores indicated that the clay material in the deeper portion of the core was often mixed with black precipitates, probably Fe-sulfides. Our results also showed that pyrite (FeS_2) formed within the wetland, but only at sites 1 and 2. Pyrite formation is not a direct by-product of microbial sulfate reduction; its formation in aquatic environments is often attributed to the reaction of Fe-monosulfides with dissolved sulfides (Berner 1984; Schoonen and Barnes 1991; Donald and Southam 1999). Our results indicate that the formation of pyrite might have been inhibited in the outflow basin (site 3), perhaps because of a low production of sulfides. However, SRB populations in October were at their greatest, which suggests a large supply of dissolved sulfides (Figure 2). Clearly, the presence of SRB alone cannot explain the absence of pyrite at site 3; the solubility of pyrite is also a function of physicochemical factors, such as the presence of sulfide-complexing agents and the concentration on Fe (Howarth et al. 1983; Howarth and Merkel 1984). In fact, our results indicate that the concentrations of dissolved Fe in the anoxic sediments of site 3 were 3 to 8 times lower than the ones at sites 1 and 2, respectively (Figure 4).

In conclusion, Fe and S cycling in the young Monahan constructed wetland was active throughout the year, especially in the cold winter months, where large SRB populations were encountered. This suggests that metal removal in young wetlands, especially Fe, is effective in temperate climates, even when the temperature of the waters decreases drastically in the winter.

BY EMAIL

Attention: Aaron MacDonell
Director of Environmental Services
Kinross Gold Corp.

Dear Aaron MacDonell,

RE: Great Bear Project Mercury Study Plan

On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows"), we write in response to the Mercury Study Plan (the "Study Plan") prepared by WSP Canada Inc. on behalf of Great Bear Resources, as per the requirement in the Tailored Impact Statement Guidelines ("TISG") issued by the Impact Assessment Agency of Canada (the "Agency" or "IAAC") for the Great Bear Gold Project (the "Project") on August 1, 2024.

The TISG requires the proponent to "submit a study plan to the Agency with sufficient time to facilitate a review by experts and interested parties and to inform the studies undertaken." With respect to the study plan, the IAAC notes in the TISG that "the potential for project contributions to methylmercury production in downstream watersheds requires a detailed and robust analysis" that includes "establishing baseline methodology and effects assessment methodology related to methylmercury." (emphasis added)

Our experts have previously raised significant concerns with respect to the quality and quantity of baseline data and monitoring completed to date, and the monitoring planned, with respect to the Great Bear Gold Project. These concerns remain. The Study Plan does not provide us with adequate assurance that this preliminary work will be accurately and adequately completed before the proponent moves forward with the necessary studies and engages in risky Advanced Exploration ("AEX") construction and mining activities. Any studies completed based on erroneous and unreliable data will not provide Grassy Narrows with the necessary information we need to properly assess the potential impacts of the Project on our inherent, Aboriginal, and Treaty rights, nor will it provide the External Technical Reviewers ("ETR") with the technically rigorous and accurate information that they need to assess the impacts of mercury and methylation during the Impact Assessment process.

Our experts are also concerned with the effects assessment methodology proposed, including the use of inadequate baseline data, unclear monitoring, flawed ML-ARD work, and unsuitable modelling software.

The proposed software has technical limitations that will prevent it from being successfully applied in the manner proposed to address the biogeochemical aspects of mercury methylation across the landscape and methylmercury uptake by biota. The Study Plan indicates that the software will not be modeled downstream of the Project site and important details, such as a

mixing zone in between “nodes”, cannot be simulated in sufficient detail. As well, the model does not intend to assess cumulative impacts and methylation potential at the discharge point, downstream and throughout the broader river system.

The Study Plan thus presents a model that is unable to predict mercury biogeochemical processes, and which is dependent on background data and proposed monitoring that is insufficient. As we address below, any study based on this Plan is bound to fail and will be inadequate for its intended purposes as outlined in the TISG.

Request for extension to provide comments

The IAAC directed the proponent to submit a study plan with “sufficient time to facilitate a review by experts and interested parties.” (emphasis added) A few weeks is not enough time for Grassy Narrows to complete the necessary review, particularly because a significant portion of the review period extended over the Christmas holidays. The holidays are one of the only times when Grassy Narrows people are usually able to lower the level of stress and anxiety that the mercury crisis and industrial threats have brought to the community. Establishing short comment periods for critical plans related to toxic threats over the holidays exacerbates the stress and anxiety which have fueled a well-documented mental health and suicide crisis in Grassy Narrows. This is a concern that Grassy Narrows has explained repeatedly to Kinross and to the IAAC. The fact that this grave concern is being ignored is emblematic of the unilateral, coercive, reckless, and disrespectful nature of this Project and this process to date. The timeline provided by Great Bear is insufficient to review the proposed Study Plan, to engage with our experts and our community in a fulsome manner, to carry out our governance process, and to develop a fulsome response.

While you insist that you will not pause your work on the Impact Assessment as you must adhere to the Impact Assessment timelines, the IAAC continues to tell us that this is not the case. The IAAC informs us that the proponent can agree to a pause in the Impact Assessment process at any time. As well, the IAAC has assured us that there is no deadline by which the proponent is required to submit the Study Plan. In fact, IAAC agreed that it would be proper for the ETR to have the opportunity to review the Study Plan and provide input prior to proceeded with the studies. The ETR Terms of Reference have yet to be set, the selection process has yet to be finalized, and its membership has yet to be selected. It is premature to close the comment period on the Study Plan.

It is in everyone’s interest for Grassy Narrows and our external experts to have enough time to review the Study Plan prior to proceeding with the study/studies to ensure that the studies are “detailed and robust”, the ETR has the information they need to adequately assess methylation-related issues, and the Impact Assessment is completed in a technically rigorous manner. If the study proceeds without sufficient time for effective peer review, or with a flawed methodology, then its results will not be reliable. It is not prudent nor rational to proceed with the Study Plan in these circumstances. We reiterate our request for an extension to provide fulsome comments.

Preliminary comments

We have been unable to complete a fulsome review of this critical document which will inform the proponent’s analysis of methylmercury, a key concern identified by Grassy Narrows during the Planning Phase of the federal Impact Assessment and throughout other regulatory review processes. However, as you insist that you will move forward with the studies without us, we are submitting our preliminary comments.

We have also enclosed two initial reports from our experts who have completed a preliminary technical review of the Study Plan to date: (1) Preliminary Report by Dr. Brian Branfireun, and (2) Preliminary Report by Dr. Kevin Morin. Note that Dr. Branfireun is an internationally recognized expert in the field of watershed biogeochemistry and the environmental cycling of mercury, including methylation, and his insights with respect to the methodologies proposed are particularly valuable.

Grassy Narrows' previous submissions should also be meaningfully integrated into a revised Study Plan, including our initial March 2024 submissions and subsequent submissions from Grassy Narrows and our experts in response to the PTTW, ECA for ISW, and Closure Plan applications. These submissions include important content that relates to the Study Plan, including information about Grassy Narrows' concerns and priorities; the sufficiency of generic guidelines for the protection of aquatic wildlife; deficiencies in the components of the planned study, including with respect to baseline data, monitoring plans, ML-ARD, groundwater modelling, and mitigation plans, among other things; and deficiencies in the review process to date.

1. **The proponent's reliance on achieving on/off site water quality that complies with PWQO and CCME water quality guidelines is inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota.**

The Plan states that to date, water quality monitoring shows that mercury and methylmercury concentrations in water are below Canadian Council of Ministers of the Environment ("CCME") water quality guidelines for the protection of aquatic life. It is clear that the proponent intends to apply CCME guidelines to the Project as "comparisons", but also as regulatory thresholds from a compliance standpoint.

Dr. Branfireun continues to opine that CCME guidelines for mercury and methylmercury are "useless for the protection of fish consumers, and even if discharges or indirect effects were a fraction of these guideline limits there would be significant potential for downstream impairments of aquatic resources." The CCME guidelines for total mercury and methylmercury for the protection of aquatic life are significantly above background levels. For example, the CCME guideline for total mercury in surface water is roughly 10-20-fold higher than uncontaminated baseline levels of mercury in the English River watershed. Previous submissions by Dr. Branfireun are clear that any increase in mercury above baseline in water would be expected to be reflected in walleye.

The CCME document itself provides that it "does not address exposure through food or bioaccumulation to higher trophic levels" and that "if the ultimate management objective for mercury is to protect high trophic level aquatic life and/or those wildlife that prey on aquatic life, more stringent site-specific application of these water quality guidelines may be necessary." Stringent site-specific guidelines are necessary in the circumstances. These site-specific guidelines must take into account the specific ecosystem, watershed, bioaccumulation, subsistence human consumers of high trophic level fish and wildlife, cumulative impacts, and the ongoing mercury crisis in Grassy Narrows. Grassy Narrows has raised this issue consistently since its first submission on the Great Bear Gold Project, and we have yet to see it reflected in the project plans including this Mercury Study Plan. The information that Grassy Narrows and its experts have provided about mercury and methylation continues to be ignored.

It is unclear what guideline levels, if any, are being proposed for sulphate, and for other parameters that impact methylation including DOC, temperature, light penetration, and pH, among others. However, the sulphate guideline levels for the receiving environment proposed in the ECA application were found by Dr. Branfireun to be entirely inappropriate for the purpose of preventing methylation impacts. If Kinross is planning to use those same levels here, then the results of this study will be erroneous.

The Study Plan must establish site specific criterion for mercury, methylmercury, sulphate, and other parameters that impact methylation, based on appropriate baseline data, and the site-specific factors noted above, not based on generic national standards that have not been designed for bioaccumulation nor for subsistence fish eaters and/or previously exposed populations. Methodology that relies on "useless" comparators and guidelines will not lead to an analysis that is "detailed and robust."

2. **The background data collected as part of the baseline studies for this Project are largely erroneous or their interpretation is flawed, which makes them insufficient to detect whether the project will have a measurable impact on fish mercury levels in the future.**

Grassy Narrows continues to raise concerns with respect to the background data collected by the proponent as part of their baseline studies. The proponent has not corrected many of the baseline study problems identified by Grassy Narrows' experts. Serious data quality problems remain and any methodology that proposes modelling based on such erroneous data will lead to study results that are inaccurate and ineffective, rendering the entire study useless, and posing serious risks to Grassy Narrows.

Dr. Branfireun continues to opine that "in the context of the protection of fish consumers, nearly all of the background data for total mercury are useless and stated incorrectly." The background mercury data in water is incorrect. The data provided for mercury are not data but are instead detection limits of the contract laboratory. The detection limits for methylmercury are higher than background levels in the English River. Concentrations reported for sulphate have also been erroneous up until May 2023 when the proponent appears to have changed analytical methods or laboratories which was not documented, contrary to best practices.

The baseline studies and proposed methodology with respect to biota are similarly inadequate. The proponent has not collected consistent species to allow for comparison between years, assessed both high trophic sport fish and low trophic indicator species, nor identified the frequency and duration of any studies.

The Study Plan relies on background data about mercury and sulphate that will inform modelling efforts and trigger undefined actions should they change. Dr. Branfireun opines that the proponent proposes to use an "inappropriate analytical approach" that will "reliably generate non-data that will not capture trends in mercury concentrations across most of the sampling sites in the project area."

The baseline studies have a number of other key deficiencies including:

1) The baseline studies are being conducted after activities that can impact methylation (such as road and machine track construction, forest clearing, drilling, soil impacts, and other industrial activities) have already occurred. This makes it impossible for most sampling sites to establish a baseline that is free of project impacts or those from other

projects.

2) Further activities that can impact methylation are planned to be carried out over the study period including extensive Advanced Exploration activity that includes activities normally considered to be mine construction. This will further interfere with the ability to establish a proper baseline.

3) There are no baseline sites in the Chukuni River that are upstream of the potential impacts of other mine sites including the Red Lake Mine and the Madsen Mine. Therefore, the baseline will likely reflect contaminated conditions which will obscure impacts from this project.

4) There are no baseline sites downstream of Pakwash Lake even though dissolved methylmercury and sulphate can travel long distances downstream and have impacts large distances from the discharge point.

5) The Plan is lacking detail so the precise sampling purpose, locations, protocols, and durations cannot be evaluated.

Grassy Narrows has repeatedly expressed a lack of trust that a profit motivated gold mining company, nor its partners, can be relied upon to establish a credible baseline. The highly critical expert reviews of the baseline work to date and the monitoring plans further substantiate Grassy Narrows' concerns. Grassy Narrows has repeatedly requested that the Crown or the proponent support Grassy Narrows to carry out a credible baseline study. However, neither the Crown nor Kinross have supported this work to date. The result is that the baseline work and plans to date are fundamentally flawed and incapable of effectively supporting risk assessment and mitigation.

Well-designed baseline studies are required to be carried out over a number of years in order to establish a baseline with a reasonable level of confidence in the range of natural variation in the baseline. Without this, it will be impossible to know whether changes seen during monitoring are due to the project or due to natural variation.

3. **Metal Leaching and Acid Rock Drainage prediction methods are improper.**

Another key input into the Study Plan is the prediction of which substances will be generated by the overburden, ore, and tailings from the project and their concentrations (ML-ARD). Previous submissions by Source Environmental note that the project has yet to complete a credible contaminants of concern assessment.

Dr. Morin similarly explains that the proponent continues to use the same ML-ARD approach and testing as Advanced Exploration and fails to follow guidance in the federal Prediction Manual of best practice and industry standards which are required under Ontario regulations. Where the proponent has committed to conducting certain tests, such as the tests for geochemical characterization, the proponent has not released most of its results.

As well, the proponent plans to use incorrect analytical methods in the proposed studies which are flawed and "will underestimate the amount of mercury in Great Bear mined materials including the walls of underground workings and pits, waste rock, overburden, soil, and tailings." Dr. Morin opines that the proposed methods are "not appropriate, reliable, and safe for the Mercury Study." He adds that the proposed groundwater modelling is similarly unreliable. Dr.

Morin concludes that he expects that the proponent will underestimate the important geochemical input and groundwater flow leaving its Gear Bear site which is “critical for a reliable outcome from the proposed Mercury Study.”

The proponent should not proceed with the Study Plan until there is high quality ML-ARD data and baseline data over multiple years for the model, and a credible monitoring plan in place. This must also be completed before the proponent proceeds with further activities that could cause potential impacts, including impacts to baseline data, for example, AEX construction, road and trail building, etc.

4. **The assimilative capacity of the receiving waters as a mitigation strategy for excess sulphate loading is not supported by the available data.**

The proponent continues to present a mitigation strategy that involves “discharging treated effluent to a large receiving watercourse (Chukuni River) that has a high oxygenation level and high assimilative capacity.” Our experts have commented on this “strategy” in previous submissions, explaining that this presents an erroneous understanding of methylation in aquatic environments. Dr. Branfireun responds in detail in his enclosed report. Dr. Branfireun concludes that:

- The strategies for treating effluent to be discharged to the Chukuni River do not target sulphate, and sulphate production from overburden and waste rock are likely to be greater than the proponent states.

- The proponent’s assessment of the watercourse’s assimilative capacity is inadequate as the proponent uses the average of entire daily discharge records for all of their dilution scenarios. There are potentially dire sulphate concentrations/volumes that could arise as a result of low flows combined with higher than stated effluent sulphate concentrations/volumes.

- The proponent relies on the high oxygenation level of the Chukuni River and does not consider the methylation potential of downstream waters, nor riparian areas and porewater, where this well-oxygenated river will deliver sulphate that may be many times in excess of background levels, in particular, to downstream mercury-sensitive lakes with high mercury methylation potential.

As with other components of this project, the cumulative impacts of this project in the context of other past, present, and planned projects does not appear to have been considered. There are at least five other gold mining projects proposed or operating in this watershed, as well as a pulp mill, sawmill, dams, diversions, clearcut logging, and municipal waste.

As well, the other mitigation measures described in the Study Plan are generally vague, unclear, and incomplete, and the list of potential effects is similarly incomplete and does not include potential effects from road and trail construction, site clearing, soil impacts, and water/dewatering, for example. There is insufficient information available for Grassy Narrows to adequately assess the proposed mitigation measures, and the information provided to date does not satisfy our experts that the proposed measures are effective and safe.

5. **The proposed model that the proponent plans to use to predict changes in sulphate, mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish cannot technically**

deliver on those outcomes.

The Study Plan states that the proponent will rely on the GoldSim software modelling package to "simulate the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project." Our experts raise significant concerns with the GoldSim software, including its inability to be applied to an environmental mercury speciation scenario, and opine that additional information on the model is required before it can be assessed as an adequate model for the methylation studies.

Dr. Morin explains that mercury and sulphate predictions will only be generated at "nodes", the areas where the user-defined "conceptual boxes" connect. This means that the predictions will not simulate waterbodies in their environmental complexity, but simply represent the internal conditions that the proponent "chooses to assume, estimate, and simulate." It is particularly concerning that the Chukuni River will only be modeled at two "nodes", immediately above and below the property boundary. There are no "nodes" in Pakwash Lake nor further downstream where there are concerns of mercury methylation. There are also no nodes at a baseline site that is upstream from the impact of other local mines and therefore reflects uncontaminated conditions. Dr. Morin explains that "because of this "node" approach, important details like an initial dilution zone (a mixing zone) in the Chukuni River between Nodes CHK-1 and CHK-2 cannot be simulated in sufficient detail."

Dr. Branfireun explains that GoldSim "does not appear to ever have been applied to an environmental mercury speciation scenario" and attributes this to the software's model which "cannot incorporate mechanistic sorption/desorption reactions along flow paths, the biomethylation process, nor the complex interaction between mercury and sulphate." Dr. Branfireun concludes that, as a result, "the model proposed can never be successfully applied in the manner that is proposed. […] A mass balance model *cannot* by definition incorporate mechanistically the input and removal processes for mercury, and *cannot* address the biogeochemical aspects of mercury methylation across the landscape which are at the root of the potential impacts associated with the Great Bear proposal."

The Study Plan, and its model, also appear to ignore a number of parameters beyond THg, meHg, and sulphate which can impact methylation dynamics including DOC, light penetration, temperature, pH, and other parameters.

We are not satisfied that the GoldSim software proposed is appropriate or technically able to apply to the circumstances and produce a useful prediction. We are concerned that the technical limitations of the software, as well as the manner in which the proponent intends to use the software, will not produce reliable, accurate, or useful predictions. Our concerns are heightened given the ongoing data quality problems in relation to the Great Bear Project – flawed data will lead to flawed results, regardless of the software chosen.

<u>Conclusion</u>

Dr. Branfireun concludes in his report:

> "We have a water quality model that is not capable of predicting mercury biogeochemical processes, that is dependent on background data and proposed monitoring that is insufficient. The outcome will be the inevitable future conclusion by the Proponent that the combination has led to an inability to adequately predict changes in methylmercury concentrations in fish because of 'uncertainties' in GoldSim output, and "unforeseen

> complexities" in coupling abiotic and biotic compartments. The reality is that these uncertainties and complexities are completely foreseeable as outlined here. […] I conclude that the TISG's requirement that the Proponent provide *a detailed and robust analysis on the potential for project contributions to methylmercury production in downstream watersheds* has not been met based on the information provided in the Mercury Plan."

In light of our experts' opinions, we are concerned with this Study Plan and require additional time to complete a fulsome review and engage with our experts in a more in depth manner, and to engage with our other experts and our community.

We reiterate our request for a 90-day extension to provide comments. It is not prudent nor rational to proceed with a Mercury Study which is built on erroneous, incomplete, and inaccurate data and which uses flawed methodology that is unable to adequately address the biogeochemical aspects of mercury methylation across the landscape as required.

We expect that the proponent will not move forward with this Study Plan, the proposed studies, or any additional work on the site that may cause adverse effects prior to receiving and meaningfully integrating our comments.

Attn: Grassy Narrows Lands Protection Team

Dear Grassy Narrows Lands Protection Team,

RE: Great Bear Mining Project - Preliminary Technical Review of the Mercury Study Plan dated December 2024

Introduction

Thank you for forwarding the Great Bear Project Mercury Study Plan by WSP Canada Inc., dated December 2024. This Study Plan is a response to the Tailored Impact Statement Guidelines (TISG) from the Impact Assessment Agency of Canada. The TISG requires a detailed investigation of mercury and methylmercury. This investigation includes interactions with sulphate some of which will be generated by proposed future mine wastes at the Great Bear Project at all relevant pH levels.

Grassy Narrows First Nation already has expertise on mercury and methylmercury. Therefore, my technical review here focuses on the portions of Section 3.4 (Methods for Forecasting Future Conditions) involving modelling within my areas of expertise. Section 3.4 begins:

> "The following sections outline the key data inputs and modeling approaches proposed to predict future conditions and potential changes from baseline levels, resulting from the Project's potential contributions to methylmercury production. Sulphate, mercury, and methylmercury concentrations in both mine site drainage and the receiving environment will be influenced by factors such as the geochemistry of ore and mine rock, the quantities and management of stockpiled materials, and the characteristics of the receiving waters."

The proposed models in Section 3.4 involve geochemistry including Metal Leaching and Acid Rock Drainage (ML-ARD or geochemical source terms), groundwater flow, and water quality as discussed in the following subsections of the Mercury Study Plan.

3.4.1 Geochemical Characterization
3.4.2 Groundwater Modelling
3.4.3 Mercury and Methylmercury Water Quality Modelling

As explained below, the proposed methods and models in these subsections of Section 3.4 are incorrect, misleading, and/or unacceptably ambiguous for assessing and predicting mercury and

sulphate on, beneath, and around the Great Bear Project. I expect the general effect of the proposed methods and models for the Mercury Study Plan will be to underestimate the leaching and transport of mercury, sulphate, and other metals and elements at the Great Bear Project.

Geochemical Characterization

Subsection 3.4.1 explains the methods that will be used to predict the aqueous concentrations and solid-phase levels for dozens of potential contaminants at the Great Bear Project, including sulphate, ML-ARD, and water quality at near-neutral pH.

This Study Plan states,

> "The sampling approach and testing methods for the geochemical investigations comply with ... guidance found within the Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND, 2009), which represents best practice and industry standard approaches and methodologies for ML/ARD sampling and characterization in Canada."

Kinross committed to the same approach and testing for Advanced Exploration at the Great Bear Project years ago, but fails to follow guidance in this federal Prediction Manual of best practice and industry standards[1]. Where Kinross did follow some guidance and detected potential for significant water-quality degradation and ML-ARD, Kinross decided this serious potential was not relevant to its Great Bear site. Where Kinross admitted to not following the guidance and using a non-recommended procedure that was cheaper, Kinross' rationale was that the non-recommended procedure was mentioned in the federal Prediction Manual as not recommended and thus Kinross was indeed following the federal Prediction Manual.

Kinross has committed to conducting many of the tests for geochemical characterization in this Subsection 3.4.1 as it did for Advanced Exploration at the Great Bear Project. However, as of early 2025, Kinross has not released most of the results for any geochemical testing.

Section 3.4.1 continues Kinross usage of the wrong analytical methods as it did for Advanced Exploration[1]. For example, Section 3.4.1 lists:

> "Solid phase elemental content analysis by aqua regia digestion and inductively coupled plasma-mass spectrometry scan"

However, Kinross fails to explain to non-technical readers that this will underestimate the amount of mercury in Great Bear mined materials including the walls of underground workings and pits, waste rock, overburden, soil, and tailings.

[1] MDAG. 2024. Review of Kinross Gold Responses to Grassy Narrows First Nation Concerns for Advanced Exploration, Concerning Metal Leaching, Acid Rock Drainage (ML-ARD), On-Site Contamination of Water, Fugitive Dust, and Hydrogeology in the ECA, PTTW, and Closure Plan Responses. Report for Grassy Narrows Lands Protection Team, dated September 5, 2024. 48 p.

This is because "aqua regia digestion" dissolves and analyzes only part of the mercury and many other elements in Great Bear mine materials, leaving behind an undetected and unknown amount of additional mercury and other elements. This is not appropriate under conditions and pathways such as fugitive dust to the environment, local-scale acidic conditions, animal inhalation, and comparisons to crustal abundances, which require "total digestion" of all mercury in a sample rather than only part of the mercury from partial "aqua regia digestion". Thus, based on the listing of methods in Section 3.4.1 for mercury, sulphate, and other elements, it is easy to overlook or miss the facts that these proposed methods are not appropriate, reliable, and safe for the Mercury Study.

Therefore, Grassy Narrows First Nation should understand that this Mercury Study Plan contains a program for Geochemical Characterization that matches that for Advanced Exploration, but Kinross has not been able to fulfill this program for Exploration to date after about two years of trying. Also, this geochemical characterization will use invalid and/or ambiguous methods that will underestimate the severity of mercury and sulphate issues at the Great Bear Project. As a result, I expect that Kinross will underestimate the important geochemical input that is critical for a reliable outcome from the proposed Mercury Study. If Kinross corrects the geochemical methods in the Mercury Study Plan to those appropriate to the Great Bear Project, then Advanced Exploration should be stopped because it is already based on invalid and/or ambiguous methods.

Groundwater Modelling

In Subsection 3.4.2, the Mercury Study Plan contains a description of the groundwater modelling that will be used to predict the flow of groundwater and likely the additional mercury loadings to the water-quality model discussed below. Similar to the Geochemical Characterization above, the procedure proposed for groundwater modelling is about the same as used for Advanced Exploration that is seriously flawed[1].

There are many errors in Kinross' modelling of groundwater flow at the Great Bear Project. Many reflect technical details that require relatively long explanations[1]. For example, groundwater modelling at the Great Bear Project apparently shows a high mound of free-standing groundwater above the land surface near Dixie Creek. This artificial and obviously wrongly modelling incorrectly restricts groundwater with mercury, sulphate, and other elements from travelling off the Great Bear site and into the surrounding environment around Dixie Creek.

Perhaps the easiest error to understand with Kinross' groundwater modelling, for both Advanced Exploration and the Mercury Study Plan, is the difference between "transient" and "steady state" groundwater modelling. Similar to surface water and many other environmental processes like temperature and rainfall, subsurface groundwater flow can shift and change daily, seasonally, yearly, over decades, and even longer due to climate change. Thus, the earth's environment is inherently "transient" through time, which can be important for defining flows and loadings of mercury, sulphate, and other elements.

Kinross does not model groundwater at the Great Bear Project using naturally transient conditions. Instead, Kinross only models groundwater at Great Bear with "steady state" conditions, where groundwater flows and loadings are constant all the time, every day, every season, every year, every decade, etc. For Advanced Exploration, at what point in the future was groundwater modelled? No one can say, but the obvious assumption is that it represents conditions a long time into the future. No one can say because Kinross continues to refuse transient modelling.

Groundwater modellers for Great Bear have stated that transient modelling is not needed despite having no transient data, no transient measurements, and no transient modelling[1]. I suspect that Kinross is strongly opposing transient groundwater modelling because it requires additional site measurements and parameters apparently not measured at the Great Bear Project.

Transient groundwater modelling at the Great Bear Project is seriously needed to understand better the impacts and effects on (1) groundwater inflows around the mine and (2) groundwater movement throughout all hydrogeologic layers and surrounding environment, as time passes. Kinross has pointed out that the effects of drought and climate change cannot be estimated, which is because only steady-state modelling was conducted.

Because steady-state modelling of some distant future but unknown time was modelled for Advanced Exploration, this is obviously the modelling that would also apply to proposed mining in the Mercury Study Plan. However, the steady-state modelling for Advanced Exploration was likely wrong but Kinross has not released the additional information from its steady-state model to confirm this.

During proposed exploration and later mining, groundwater will be drawn from all depths into the underground mine at least 500 meters (0.5 km) deep vertically. However, Kinross will release only the drawdown map for the uppermost 36 m of overburden, and not the remaining ~500 m vertical thickness of rock. This incorrectly implies (1) drawdown happens instantaneously for long lateral distances throughout the Great Bear site and (2) transient conditions are minor because they will only be up to 36m vertically.

In situations where groundwater levels will fluctuate more than 500 meters vertically, non-steady "transient" modelling is certainly needed. In fact, groundwater levels, forced by Kinross pumping, varying by roughly 500 m vertically (varying by roughly 0.5 kilometers below the land surface) at the Great Bear Project is one of the best examples of where transient groundwater modelling is critical for reliable and realistic flow directions and associated loadings of mercury, sulphate, and other elements. The proposed open pits at Great Bear will also lead to significant transient groundwater flows and geochemical loadings like mercury and sulphate closer to the land surface but are ignored by Kinross.

Additionally, Kinross misleads by indicating shallow contaminated groundwater will not escape to the environment but would be drawn into the pumped-down underground mine[1]. This is false at early times and only becomes reasonable after unknown longer times as steady-state conditions are approached. The lack of transient modelling prevents anyone from proving how long it will take to

reach steady-state conditions and prevent contaminated groundwater from escaping.

Based on this error alone of steady-state groundwater modelling, Section 3.4.2 of the Mercury Study Plan is remarkable in that it simply states,

> "These numerical groundwater flow models [of FEFLOW 7.2] consider three dimensional steady-state flow conditions and implement an equivalent porous media approach which is deemed sufficient for characterizing the overall groundwater flow regime at the scale of this analysis."

This is wrong, because FEFLOW 7.2 can also simulate transient conditions. Kinross is misleading readers here by not revealing the full capability of this groundwater model including transient modelling needed for the Mercury Study and for general impacts of the Project. In any case, it is clear that steady-state, always-the-same-and-not-varying groundwater modelling, for conditions at some distant but unknown time, will be used to unreliably simulate the critical groundwater pathways and loadings for mercury and sulphate at the Great Bear Project.

Furthermore, the second part of the quotation above on "equivalent porous media" deceptively hides another important flaw. Groundwater moving through irregular and scattered cracks (fractures) in Great Bear rock will be instead incorrectly modelled as smoothed layers like sand and gravel. Kinross has cryptically "deemed sufficient" this unrealistic modelling based on no data and no evidence that groundwater flow through fractured rock at Great Bear is like groundwater flow through sand, gravel, silt, etc. Without proof otherwise, the porous-media modelling planned for the Mercury Study is not "sufficient" and is plain wrong and misleading.

Therefore, Grassy Narrows First Nation should understand that this Mercury Study Plan contains a program for Groundwater Modelling that matches that for Advanced Exploration. The current groundwater modelling is unreliable and likely wrong in light of many incorrect and unjustified assumptions made by Kinross. The Mercury Study Plan shows these errors will be continued, including the false assumption that groundwater flow will be steady state during mining, being the same every day, every season, every year, every decade, etc. As a result, I expect that Kinross will underestimate the important groundwater flow leaving its Great Bear site. Along with problems with the proposed Geochemical Characterization discussed above, this will underestimate the loadings of mercury, sulphate, and other elements leaving the Great Bear site. This will preclude a reliable outcome from the proposed Mercury Study. If Kinross corrects the proposed groundwater modelling in the Mercury Study Plan, then Advanced Exploration should be stopped because it is already based on the misleading and wrong modelling.

Water-Quality Modelling

Section 3.4.3 on water-quality modelling explains that the model called GoldSim will be used for water-flow and water-quality modelling at the Great Bear Project. Here are some statements from Section 3.4.3 about the GoldSim model.

- GoldSim will "stimulate [sic] the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project".

- "The GoldSim model domain includes waterbodies potentially impacted by the Project within the PA, LSA and RSA."

It is not clear from these statements that GoldSim is not like models such as groundwater (see above) that simulate the movement and chemistry of waters (1) across a site-wide grid of mathematical elements or (2) along a grid of mathematical elements along lake or a creek like Dixie Creek where groundwater can alternately enter and exit the surface waterbodies over short distances.

Instead, GoldSim uses user-defined "compartments" or "conceptual boxes" such as one for the western portion of Dixie Creek near the Great Bear site and another for the eastern portion near the site. The human modellers then conceptually connect these two boxes and any other selected boxes in the GoldSim model to create "nodes". Then the modellers choose the inputs, outputs, and internal conditions and processes that they think apply to each box and node. This should include variable and transient conditions that exist at the Great Bear site over days, seasons, years, and decades, but we already know from the proposed groundwater modelling that transient conditions for at least one important pathway for mercury and sulphate will be ignored and thus will not reliable (see above).

Now it is clearer what Kinross means by saying,

> "Sulphate, mercury and methylmercury predictions will be generated for waterbodies represented by model nodes shown in Figure 3-2."

Thus, predictions for mercury and sulphate will be generated only at "nodes" that do not literally simulate waterbodies in their environmental complexity, but simply represent the "boxes" and "nodes" and internal conditions that Kinross chooses to assume, estimate, and simulate.

Figure 3-2 in the Mercury Study Plan shows that the Chukuni River will be modelled only at two nodes: CHK-1 immediately above the property boundary and CHK-2 immediately below the boundary. Therefore, everything above the property boundary in the Chukuni River will be simulated as a single "node" or "box" for which the modellers will define all the upstream physical, geochemical, and water-quality properties, likely with many simplifications and/or assumptions. Then the physical and chemical contributions from Dixie Creek Node DIX-5 will be "mixed" with Node CHK-1 to obtain predicted flows and concentrations at Node CHK-2, subject to currently unstated simplifications and/or assumptions possibly like adsorption on river-bed sediments or biological processes to remove additional mercury and sulphate from the water at CHK-2. Because of this "node" approach, important details like an initial dilution zone (a mixing zone) in the Chukuni River between Nodes CHK-1 and CHK-2 cannot be simulated in sufficient detail. This gives you some idea how the GoldSim model will "simulate" water flow and water quality at, beneath, and around the Great Bear site.

The GoldSim model for the Great Bear Project can be easily manipulated by the modellers but this is hidden from external inspection by Grassy Narrows First Nation. For example, the modellers can apply a condition where aqueous concentrations of mercury, sulphate, and other elements are allowed to decrease but are not allowed to increase as water "flows" through the boxes and nodes. Section 3.4.3 promises to "[p]rovide a clear description and rationale for model input parameters and assumptions". This is appropriate and important but in my experience I have never seen this

provided in sufficient detail for any GoldSim model.

Therefore, to understand how the GoldSim water-quality model for the Great Bear Project has been designed and manipulated through all of its boxes and nodes, and thus whether its results and predictions are reasonable, a relatively large amount of information on the GoldSim model will be needed from Kinross. I have not seen this provided in detail before, but it will be required for the Great Bear Mercury Study.

Conclusion

As explained above, the proposed methods and models in the subsections of Section 3.4 of the Mercury Study Plan are incorrect, misleading, and/or unacceptably ambiguous for assessing and predicting mercury and sulphate on, beneath, and around the Great Bear Project. I expect the general effect of the proposed methods and models for the Mercury Study Plan will be to underestimate the leaching and transport of mercury, sulphate, and other metals and elements at the Great Bear Project.

Sincerely,

Kevin A. Morin, Ph.D., P.Geo., L.Hydrogeo.
President

Technical Memo

To: **Joseph B. Fobister, Lead Negotiator (Grassy Narrows Land Protection Team), David Sone (ANA Advisor), Jackie Esmonde (Legal Counsel) and Sydney Lang (Legal Counsel) of the ANA Advisory Team**

From: **Rina Freed (Ph.D., P.Eng.), Georgina Farah, B.Sc.**

Date: **April 29th 2025**

Subject: **Review of the Great Bear Resources Mercury Study Plan**

Source has been retained by Asubpeeschoseewagong Anishinabek (ANA) Land Protection Team to provide comments on the proposed Great Bear Project. This technical review provided to ANA is in relation to a Mercury Study Plan, a requirement of the Tailored Impact Statement Guidelines issued for the project in August 2024.

The objectives of the Mercury Study Plan are to outline baseline methodology and to identify project contributions to mercury / methylmercury generation in downstream waterbodies. Industrial mercury pollution originated from the Dryden Paper Mill in the 1960s and 1970s, causing mercury contamination in the English-Wabigoon River and mercury related conditions in Grassy Narrows people. As a result, ANA community members are especially concerned with mercury pollution. Formation of methylmercury is of considerable concern within the watersheds surrounding the proposed Great Bear Project which contain mercury from geological sources, atmospheric deposition from distant industrial sources, and potentially local industrial sources such as hydro damming and clearcut logging. Methylmercury is a species of mercury that bioaccumulates and biomagnifies in consumers, causing accumulation in the food chain.

The following comments are not exhaustive and are limited to areas within the expertise of the authors, and should be read in conjunction with reviews by other experts and by ANA.

Alignment with Tailored Impact Statement Guidelines (TISG)

1. **Lack of Maps for Proposed Study Areas:**

   Section 7.3.1 of the Great Bear Project TISG states the impact statement for each valued component (VC) identified must describe the spatial boundaries of said VC and a rationale for the boundaries. These spatial boundaries must be shown on maps in each impact statement.

The Mercury Study Plan does not include maps for the PA (Project Area), LSA (Local Study Area) and RSA (Regional Study Area) identified for the VC methylmercury, which makes it hard for reviewers to understand where the boundaries lie and the reasoning behind them. These maps should be included in the Mercury Study Plan.

2. Regional Study Area for Cumulative Effects

An identified VC in the TISG is the health of Indigenous Peoples in relation to potential changes in the surrounding watershed. This includes downstream water quality from effluent discharge and past industrial activity.

More explanation is required in the Study Plan to explain how cumulative effects are addressed. For example, the Regional Study Area (RSA) described in the Mercury Study Plan may be too narrow for a cumulative effects assessment, as it does not include areas of significant historic mercury contamination such as the English-Wabigoon River system which are downstream of the proposed industrial effluent discharge point. To ensure a comprehensive assessment of cumulative effects for this identified VC, the RSA should be expanded to include areas of historic mercury contamination that have impacted ANA.

Baseline Methodology

3. Inclusion of the Exploration Phase in the Study Plan

The Study Plan should include the proposed underground exploration phase as well as the Life of Mine project described in the Project Description (January 2024). Please indicate if the exploration project phase is included in the study plan. This phase has the potential to generate methylmercury, as noted in previous submissions, and should be included in the study. This should include both early exploration activities, and the “Advance Exploration” program, which includes construction of key components of the mine.

4. Documentation of Missed Sampling Events

Establishing a sufficient baseline dataset is critical for conducting an effects assessment. In section 2.2 Summary of Analytical Methodology, water quality will be sampled monthly providing flow is present and the site can be safely accessed. To ensure a complete dataset, the proponent should ensure any missed sampling events are recorded with a rationale and attempts to re-sample the location(s) should be made within the monthly sampling period.

In order to establish a reliable baseline dataset, sampling should be carried out over three years, and should include monthly sampling, as well as 5 samples in 30 days during periods of low and high flows.

Also, in order to establish a valid baseline, the proponent should ensure that appropriate baseline monitoring sites are established which:

a. Do not reflect regional sources of contamination (eg. upstream mines),
b. Do not reflect contamination from earlier stages of this project,
c. Reference stations that will not be impacted by later stages of this project,
d. Will continue to be monitored throughout the project.

The proponent should also ensure that the correct sampling and lab methodology are used to ensure that all contaminant levels above baseline are detected reliably.

5. Inclusion of Mercury, Methylmercury and Sulphate Loadings

Loadings may be a useful measurement of mercury, methylmercury and sulphate and provide an indication of the total mass of these parameters anticipated in the project waterbodies. The study plan should include a requirement to develop monthly predictions of loadings for mercury, methylmercury and sulphate (and other substances affecting methylation) that may enter the project area waterbodies, including the Chukuni River.

6. Baseline Sampling Locations

Methylmercury concentrations observed in monitoring data in the project area ranged from 1.98% to 14.35% (of total mercury) reflecting that there are certain project areas that generate more methylmercury than others. The Study Plan should provide a rationale of how both surface water and groundwater sampling locations in the Study Plan have been chosen in relation to expected direct and indirect effects and discuss the potential influence of project waters on wetted areas. Given that methylmercury is primarily generated under anoxic conditions, which can vary across the project site, the Study Plan should provide a rationale as to how the baseline sampling locations are sufficient to capture the range in methylmercury. Currently, the Mercury Study Plan does not include a sufficient level of detail for each proposed monitoring site to assess whether the purpose or rationale of the location fulfills the intent of the baseline program. The program should ensure that each downstream sampling point is sufficient to establish a robust baseline against which any changes in downstream water quality related to mercury and methylation can be measured.

7. Unnamed Waterbodies #1 and #2

According to Section 2.2.1 Water Quality, seasonal baseline surface water quality sampling for temperature, pH and dissolved oxygen occurs in Pakwash Lake, Genesee Lake and Unnamed Waterbody #6. The Study Plan should include a rationale as to why there is no planned physicochemical property sampling proposed for Unnamed Waterbodies #1 and #2.

Additionally, the Study Plan should list which waterbodies are included in the multi-season fish habitat assessments.

8. Additional Data Request- Water Quality

Baseline water quality reporting should include the 95th percentile, minimum and maximum values for all waterbodies sampled, as well as an assessment of seasonal variation. Figures should be provided showing seasonal variation for the range in mercury, methylmercury and sulphate baseline data. Baseline data should cover 3 years and include monthly sampling, as well as 5 samples in 30 days during periods of low and high flows.

9. Mercury and Methylmercury in Temporary Closure

Spatial and temporal boundaries for the effects assessment are discussed by phase of mine life. However, there is no discussion of a Care and Maintenance phase, which commonly occurs in mining, according to economic conditions. Mines often plan for operations and closure phases but lack rigorous assessment of temporary closures and their implications for the receiving environment. The effects assessment cannot be considered complete without an assessment of a temporary closure scenario. The proponent should consider a 'worst case scenario' during operations, where the mine is forced to temporarily shut down. Implications for water management, water treatment and potential for adverse effects related to mercury, methylmercury and sulphate in a care and maintenance scenario should be assessed in the Study Plan.

10. Traditional Food Harvesting Considerations

While the sampling locations proposed as part of the Mercury Study Plan attempt to assess the impact of effluent release on water quality as it flows through the waterbodies surrounding the mine site, there is no discussion in the Mercury Study Plan regarding how it will assess potential impacts on human health or how the movement of fish and other species that are consumed will be considered. For example, Great Bear should assess, as part of the Mercury Study Plan, how far key fish species for Indigenous consumption, including walleye, migrate to and from the project site, its receiving waters, and downstream water bodies that are potentially impacted. How does the study plan presented account for movement of species that will ultimately be consumed potentially outside of the study area? The study plan also does not apply consumption guidelines that are designed for Indigenous subsistence consumers of fish, nor does it consider the pre-existing mercury exposure that Grassy Narrows people have experienced. The study plan does not appear to take into account the unique mercury risks associated with Grassy Narrows people who consume fish as part of their way of life and who have previously experienced high levels of mercury exposure.

Effects Assessment Methodology

11. Lack of Data Provided on Geochemical Characterization to Date

Section 8.3.1. of the TISG provided for the Great Bear Project states that the associated Impact Statement should describe the representativeness of samples collected for acid rock drainage and metal leaching. Despite the Mercury Study Plan stating that baseline geochemical data has been collected since 2022, the plan does not indicate the location of samples or the results of testing thus far. The existing data for baseline geochemical analysis that will be included in the water quality model (GoldSim) for methylmercury should be provided. Significant deficiencies in the ML-ARD data and study plan have been identified by Source and by other reviewers in previous submissions. These deficiencies should be corrected, and the associated studies completed and reviewed, before the geochemical data is used as an input in the effects assessment.

12. Quality Assurance for Geochemical Samples

The methodology for geochemical characterization described in Section 3.4.1 of the Mercury Study Plan does not include quality assurance / quality control procedures, including but not limited to laboratory certificates of analysis as requested in Section 8.3.1 of the TISG. What are the procedures to follow for quality assurance / quality control for samples taken for geochemical characterization?

13. Inclusion of Worst Case Scenario in Water Quality Modelling

Section 8.3.2 of the TISG states the Impact Statement for the Biophysical Environment must provide base case (i.e. most likely, mean, median) and worst case (e.g. 75^{th}-90^{th} percentile) scenarios, plus any applicable sensitivity scenarios. However, the Mercury Study Plan indicates the GoldSim model used for Mercury and Methylmercury Water Quality Modelling (Section 3.4.3) will only identify and describe the base case (expected case) plus sensitivity scenarios. This is not considered appropriate as the worst case scenario should also be included in future modelling for mercury and methylmercury concentrations. Considering the legacy of mercury contamination in the surrounding region, it is critical that the ‘worst case’ is considered and modelled, not just the expected scenario.

Conclusion

Thank you for the opportunity to provide a review of the drafted Mercury Study Plan for the Great Bear Project. If you have any questions, please contact the undersigned.

Yours truly,

Source Environmental Associates Inc.

Draft Mercury Study Plan

Great Bear Resources Ltd.'s Response to January 31, 2025 Letter from Asubeechoseewagong Netum Anishinabek

#	Comments	Great Bear Resources Response
A. The proponent's reliance on achieving on/off site water quality that complies with PWQO and CCME water quality guidelines is inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota		
A1	The Plan states that to date, water quality monitoring shows that mercury and methylmercury concentrations in water are below Canadian Council of Ministers of the Environment ("CCME") water quality guidelines for the protection of aquatic life. It is clear that the proponent intends to apply CCME guidelines to the Project as "comparisons", but also as regulatory thresholds from a compliance standpoint.	Water quality modeling will use the both baseline water quality data and a suite of available guidelines for mercury and methylmercury, as proposed in the Mercury Study Plan to assess results of the modelling. This includes the existing CCME guideline (4 ng/L) as a benchmark for comparisons. This is an industry-standard approach based on available guidance documents. Additionally, biomagnification and food web modeling will be incorporated into the Mercury Study Plan to provide a complementary line of assessment beyond what water quality guideline comparisons alone may be able to capture. This approach will account for potential mercury and methylmercury bioaccumulation through the food web, including in fish consumed by both humans and wildlife (e.g., forage and sport fish). Regardless of the water quality guidelines applied, the Human Health and Ecological Risk Assessment (HHERA) will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish concentrations and consumption for members of the local communities.
A2	Dr. Branfireun continues to opine that CCME guidelines for mercury and methylmercury are "useless for the protection of fish consumers, and even if discharges or indirect effects were a fraction of these guideline limits there would be significant potential for downstream impairments of aquatic resources." The CCME guidelines for total mercury and methylmercury for the protection of aquatic life are significantly above background levels. For example, the CCME guideline for total	Water quality modeling will use the both baseline water quality data and a suite of available guidelines for mercury and methylmercury, as proposed in the Mercury Study Plan to assess results of the modelling. This includes the existing CCME guideline (4 ng/L) as a benchmark for comparisons. This is an industry-standard approach based on available guidance documents. Additionally, biomagnification and food web modeling will be incorporated into the Mercury Study Plan to provide a complementary line of assessment beyond what water quality guideline comparisons alone may be able to capture. This approach will account for potential mercury and methylmercury bioaccumulation

#	Comments	Great Bear Resources Response
	mercury in surface water is roughly 10-20-fold higher than uncontaminated baseline levels of mercury in the English River watershed. Previous submissions by Dr. Branfireun are clear that any increase in mercury above baseline in water would be expected to be reflected in walleye.	through the food web, including in fish consumed by both humans and wildlife (e.g., forage and sport fish). Regardless of the water quality guidelines applied, the HHERA will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish concentrations and appropriate consumption rates for members of the local communities.
A3	The CCME document itself provides that it "does not address exposure through food or bioaccumulation to higher trophic levels" and that "if the ultimate management objective for mercury is to protect high trophic level aquatic life and/or those wildlife that prey on aquatic life, more stringent site-specific application of these water quality guidelines may be necessary." Stringent site-specific guidelines are necessary in the circumstances. These site-specific guidelines must take into account the specific ecosystem, watershed, bioaccumulation, subsistence human consumers of high trophic level fish and wildlife, cumulative impacts, and the ongoing mercury crisis in Grassy Narrows. Grassy Narrows has raised this issue consistently since its first submission on the Great Bear Gold Project, and we have yet to see it reflected in the project plans including this Mercury Study Plan. The information that Grassy Narrows and its experts have provided about mercury and methylation continues to be ignored.	Regardless of the water quality guidelines applied for comparison purposes, the HHERA will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish and appropriate consumption rates for members of the local communities. Fish concentrations will be predicted based on a food web model that considers the potential for bioaccumulation. The aquatic food web modelling will be based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling.
A4	It is unclear what guideline levels, if any, are being proposed for sulphate, and for other parameters that impact methylation including DOC, temperature, light penetration, and pH, among others. However, the sulphate guideline levels for the receiving environment proposed in the ECA application were found by Dr. Branfireun to be entirely inappropriate for the	A key objective of the Mercury Study Plan is to assess how potential changes in sulfate concentrations may influence methylmercury production in the receiving environment. This includes evaluating the relationships between sulfate, and other water quality parameters within the context of methylmercury production. Rather than only relying on predefined sulfate thresholds, or data from dissimilarly impacted environments, the study has been designed to collect and use site-specific data — an approach which aligns with best practice and available regulatory guidance.

#	Comments	Great Bear Resources Response
	purpose of preventing methylation impacts. If Kinross is planning to use those same levels here, then the results of this study will be erroneous.	Regarding the sulfate levels referenced in the ECA application for the advance exploration program, the Mercury Study Plan is not simply adopting those values. Instead, a process-based approach is proposed to evaluate sulfate's role in the production of methylmercury and the potential for bioaccumulation.
A5	The Study Plan must establish site specific criterion for mercury, methylmercury, sulphate, and other parameters that impact methylation, based on appropriate baseline data, and the site-specific factors noted above, not based on generic national standards that have not been designed for bioaccumulation nor for subsistence fish eaters and/or previously exposed populations. Methodology that relies on "useless" comparators and guidelines will not lead to an analysis that is "detailed and robust."	Please see responses to comments A1 and A2, above. Dismissing the study's validity based on an assumption about guideline application misrepresents its intent and proposed methodology. Regardless of the water quality guidelines applied for comparison purposes in the Impact Statement, the HHERA will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish and appropriate consumption rates for members of the local communities. Fish concentrations will be predicted based on a food web model that takes into account the potential for bioaccumulation. The aquatic food web modelling will be based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Appropriate mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling.
B.	**The background data collected as part of the baseline studies for this Project are largely erroneous or their interpretation is flawed, which makes them insufficient to detect whether the project will have a measurable impact on fish mercury levels in the future.**	
B1	Grassy Narrows continues to raise concerns with respect to the background data collected by the proponent as part of their baseline studies. The proponent has not corrected many of the baseline study problems identified by Grassy Narrows' experts. Serious data quality problems remain and any methodology that proposes modelling based on such erroneous data will lead to study results that are inaccurate and ineffective, rendering the	Baseline conditions refers to pre-project, existing environmental conditions, consistent with industry-standard effects assessment methodologies and the Tailored Impact Statement Guidelines for the Project. Baseline sampling programs were initiated in 2019 (noting that the construction of Project has not as been initiated as the Project has not been approved yet), and have been designed to be extensive and appropriate to inform the effects assessment. The repeated claim that background data collected as part of ongoing baseline studies are "useless" is unfounded and inaccurate. They have been designed to be extensive and appropriate to inform the effects assessment, and encompass a comprehensive

#	Comments	Great Bear Resources Response
	entire study useless, and posing serious risks to Grassy Narrows.	network of sites strategically selected to capture and characterize spatial and temporal variations. The site-specific data is analyzed at third-party accredited laboratories - an approach which aligns with best practice and available regulatory guidance. The specific concerns raised by Grassy Narrows have most recently been addressed in the October 25, 2024 memorandum "*Response to ANA Letter Concerning Great Bear Project AEX ECA ISW Application and Expected Impacts to the Chukuni River*". Key points are as follows: *"The water quality laboratory analyses have been conducted using industry-approved methods at accredited laboratories (Canadian Association for Laboratory Accreditation). It is important to clarify that while ICP-MS has been used for total metal scans, it has not been employed for mercury quantification since 2021 such that detection limits of ongoing analyses are much lower. Starting in 2022, sulphate and mercury monitoring on the Chukuni River has included the following analyses:* • *Methylmercury by Distillation, Aqueous Ethylation, Purge and Trap, and Cold Vapor Atomic Florescence Spectroscopy (CVAFS) at specialized laboratories[a] with reported detection limits of approximately 0.0035 ng/L* • *Ultra-low mercury by Oxidation, Purge, and Trap, and CVAFS at specialized laboratories with reported detection limits of approximately 0.04 ng/L* • *Standard mercury by Cold Vapor Atomic Absorption Spectroscopy (CVASS) with reported detection limits of approximately 5 ng/L* • *Sulphate (method E235.S04) with reported detection limits of approximately 0.3 mg/L* *The analytical methods used and the reported detection limits (DL) are sufficiently sensitive to characterize the existing water quality of the Chukuni River. Dr. Branfireun correctly noted that analytical results below the reported DL were retained in the water quality database and included in the statistical summaries presented in the Application. This approach is consistent with established*

[a] Ultra low (ultra trace) analyses are offered by a limited number of specialized laboratories in Canada that use specialized analytical techniques and laboratory measures to avoid potential for cross contamination. Baseline ultra data for the AEX Program has been completed at Flett Research Ltd.

#	Comments	Great Bear Resources Response
		guidance on environmental data handling (Environment and Climate Change Canada, 2014; Environmental Protection Agency, 1990), reflects industry standards and regulator expectations, and is appropriate to support baseline database creation. *For sulphate concentrations, it is noted by Dr. Branfireun that there is variation in reported water quality data over the period of record, such that sulphate data is not useful. Water quality in natural systems is inherently dynamic and can fluctuate even over short periods due to a range of environmental factors, such as precipitation, runoff, temperature changes, and natural heterogeneity in ice cover. The variation identified by Dr. Branfireun of 7 mg/L sulphate on 2022-December-15 and 1 mg/L sulphate on 2022-December-19, as being erroneous, is consistent with expected natural variability and does not undermine the reliability of the overall dataset, which includes hundreds of data points. Such fluctuations are typical in natural aquatic environments.*
B2	Dr. Branfireun continues to opine that "in the context of the protection of fish consumers, nearly all of the background data for total mercury are useless and stated incorrectly." The background mercury data in water is incorrect. The data provided for mercury are not data but are instead detection limits of the contract laboratory. The detection limits for methylmercury are higher than background levels in the English River. Concentrations reported for sulphate have also been erroneous up until May 2023 when the proponent appears to have changed analytical methods or laboratories which was not documented, contrary to best practices.	Baseline conditions refers to pre-project, existing environmental conditions, consistent with industry-standard effects assessment methodologies and the Tailored Impact Statement Guidelines for the Project. Baseline sampling programs were initiated in 2019 (noting that the construction of Project has not as been initiated as the Project has not been approved yet), and have been designed to be extensive and appropriate to inform the effects assessment. 		variability and does not undermine the reliability of the overall dataset, which includes hundreds of datapoints. Such fluctuations are typical in natural aquatic environments.
B3	The baseline studies and proposed methodology with respect to biota are similarly inadequate. The proponent has not collected consistent species to allow for comparison between years, assessed both high trophic sport fish and low trophic indicator species, nor identified the frequency and duration of any studies.	Baseline mercury data from over 320 fish samples has been collected from the Project waterbodies representing high trophic sport fish (Walleye and Northern Pike) and insectivorous fish such as sucker and minnow species as shown in the table below. The intent was to document baseline contaminants in fish across the project area representative of multiple types of habitats. This results in a variety of species sampled depending on what is present in those habitats. Consistent species were used when available, however, species presence varied by location as is normal in the natural environment where conditions are not rigid unlike a laboratory. Detailed methodology of the fish tissue collections will be included in baseline documentation appended to the Impact Statement. With respect to the Mercury Study Plan, exposure and reference stations will be used and species-specific fish collection made with appropriate numbers of samples to allow for statistical comparisons. In additional to fish, other components of the food web have been sampled as per the table below.

Web Component / Trophic Level	Species	Location	Number of Samples
Carnivore (Piscivore) Fish	Northern Pike Walleye Yellow Perch	Dixie Creek Chukuni River Genessee Lake Unnamed Waterbodies	175
Omnivorous Fish	Lake Whitefish	Chukuni River	2
Insectivorous Fish	Silver Redhorse White Sucker Brook Stickleback Central Mudminnow Finescale Dace Iowa Darter Lake Chub Northern Redbelly Dace Spottail Shiner Yellow Perch	Dixie Creek Chukuni River Genessee Lake Unnamed Waterbodies Unnamed Watercourses	145

#	Comments	Great Bear Resources Response
B4	The Study Plan relies on background data about mercury and sulphate that will inform modelling efforts and trigger undefined actions should they change. Dr. Branfireun opines that the proponent proposes to use an "inappropriate analytical approach" that will "reliably generate non-data that will not capture trends in mercury concentrations across most of the sampling sites in the project area."	The aquatic food web modelling will be based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Appropriate mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling.
C. The baseline studies have a number of other key deficiencies including:		
C1	The baseline studies are being conducted after activities that can impact methylation (such as road and machine track construction, forest clearing, drilling, soil impacts, and other industrial activities) have already occurred. This makes it impossible for most sampling sites to establish a baseline that is free of project impacts or those from other projects.	Baseline conditions refers to pre-project, existing environmental conditions, consistent with industry-standard effects assessment methodologies and the Tailored Impact Statement Guidelines for the Project. Baseline sampling programs were initiated in 2019 - noting that the construction of Project has not as been initiated as the Project has not been approved yet. Accordingly, this statement is incorrect. The project baseline studies include reference stations located away from potential future project influence as appropriate, including upstream stations for water-related studies.
C2	Further activities that can impact methylation are planned to be carried out over the study period including extensive Advanced Exploration activity that includes activities normally considered to be mine construction. This will further interfere with the ability to establish a proper baseline.	As noted above, baseline conditions refers to pre-project, existing environmental conditions, consistent with industry-standard effects assessment methodologies and the Tailored Impact Statement Guidelines for the Project. Baseline sampling programs were initiated in 2019 - noting that the construction of Project has not as been initiated as the Project has not been approved yet. Accordingly, this statement is incorrect. Utilizing an abundance of caution, Great Bear Resources will be using baseline data for the Impact Statement reflecting the monitoring prior to receiving Advanced Exploration permits.

#	Comments	Great Bear Resources Response
C3	There are no baseline sites in the Chukuni River that are upstream of the potential impacts of other mine sites including the Red Lake Mine and the Madsen Mine. Therefore, the baseline will likely reflect contaminated conditions which will obscure impacts from this project	Baseline conditions refers to pre-project, existing environmental conditions, consistent with industry-standard effects assessment methodologies and the Tailored Impact Statement Guidelines for the Project. Baseline sampling programs were initiated in 2019 - noting that the construction of Project has not as been initiated as the Project has not been approved yet. Accordingly, this statement is incorrect. The baseline conditions at the Project site do reflect the historic and ongoing industrial and residential developments in the upstream watershed. These developments are unrelated to the Project and reflect existing conditions.
C4	There are no baseline sites downstream of Pakwash Lake even though dissolved methylmercury and sulphate can travel long distances downstream and have impacts large distances from the discharge point.	The baseline program supporting the effects assessment currently extends downstream to the outlet of Pakwash Lake, over 20 km from the proposed discharge location and is sufficient to support the effects assessment. Project discharge is estimated to contribute less than 1% of total flows. If necessary, study area boundaries will be reassessed following modeling to ensure they adequately capture and evaluate potential Project effects.
C5	The Plan is lacking detail so the precise sampling purpose, locations, protocols, and durations cannot be evaluated.	Sampling locations and stations, frequency of sampling, and identification of analytical methodology is presented in Section 2 of the Mercury Study Plan, including maps (Figures 2.2 though Figures 2-5). Baseline reports were provided to ANA in April 2025.
C6	Grassy Narrows has repeatedly expressed a lack of trust that a profit motivated gold mining company, nor its partners, can be relied upon to establish a credible baseline. The highly critical expert reviews of the baseline work to date and the monitoring plans further substantiate Grassy Narrows' concerns. Grassy Narrows has repeatedly requested that the Crown or the proponent support Grassy Narrows to carry out a credible baseline study. However, neither the Crown nor Kinross have supported this work to date. The result is that the baseline work and plans to date are fundamentally flawed and incapable of effectively supporting risk assessment and mitigation.	On October 3, 2024, Great Bear Resources and Asubeechoseewagong Netum Anishinabek (ANA) entered into an Interim Funding Agreement establishing a financial commitment of $722,650.00 to support ANA's meaningful engagement in the review of the Great Bear Project. Of this amount, $300,000.00 was specifically allocated to support ANA's technical review of documentation related to the Impact Assessment and associated supporting materials. Great Bear provided detailed work plans to Grassy Narrows and the Ministry in June 2023, followed by comprehensive Baseline Reports in April 2024. These submissions were developed to align with provincial and federal regulatory requirements, and were informed by multi-season field programs, input from regulatory agencies, and available Indigenous Knowledge where shared. The work was completed using standard scientific methods and is consistent with industry best practices and

#	Comments	Great Bear Resources Response
		applicable guidance documents. The methodologies, data, and results remain open to review, discussion, and refinement where warranted. Baseline conditions refers to pre-project, existing environmental conditions, consistent with industry-standard effects assessment methodologies and the Tailored Impact Statement Guidelines for the Project. Baseline sampling programs were initiated in 2019 (noting that the construction of Project has not as been initiated as the Project has not been approved yet), and have been designed to be extensive and appropriate to inform the effects assessment. The repeated claim that background data collected as part of ongoing baseline studies are not credible and fundamentally flawed, is unfounded and inaccurate. They have been designed to be extensive and appropriate to inform the effects assessment, and encompass a comprehensive network of sites strategically selected to capture and characterize spatial and temporal variations. The site-specific data is analyzed at third-party accredited laboratories - an approach which aligns with best practice and available regulatory guidance. The 2024 baseline workplans were submitted to ANA in June 2023. To date, we have not received any comments or direction in response. Despite our repeated efforts to advance the work, we have yet to receive any guidance on what ANA is specifically looking for to consider their concerns satisfied.
C7	Well-designed baseline studies are required to be carried out over a number of years in order to establish a baseline with a reasonable level of confidence in the range of natural variation in the baseline. Without this, it will be impossible to know whether changes seen during monitoring are due to the project or due to natural variation	Thank you for confirming our approach to a well-design baseline study is appropriate. Baseline studies were initiated in 2019, and detailed aquatic baseline investigations were conducted over a three year period, from 2022 to 2024 at locations within the proposed Project footprint, as well as peripheral locations beyond the Project to characterize baseline conditions throughout the area. Sampling stations were generally consistent between years with minor adjustments to reflect the needs of the ongoing program and site conditions.
D. Metal Leaching and Acid Rock Drainage prediction methods are improper.		

#	Comments	Great Bear Resources Response
D1	Another key input into the Study Plan is the prediction of which substances will be generated by the overburden, ore, and tailings from the project and their concentrations (ML-ARD). Previous submissions by Source Environmental note that the project has yet to complete a credible contaminants of concern assessment.	ANA has previously made numerous false claims that geochemical and other studies being conducted for the Project are not credible. Great Bear Resources has previously addressed these comments. As previously indicated, baseline geochemical characterization programs have been conducted and are continuing for the Project, following industry standard methods, under the direction of experienced professional geoscientists. This includes the assessment of ML/ARD potential for mine rock, ore, tailings, and overburden, per the approaches and methods in MEND (2009). The results of these studies will be used to assess potential environmental effects of the Project and ensure that they are appropriately mitigated and managed.
D2	Dr. Morin similarly explains that the proponent continues to use the same ML-ARD approach and testing as Advanced Exploration and fails to follow guidance in the federal Prediction Manual of best practice and industry standards which are required under Ontario regulations. Where the proponent has committed to conducting certain tests, such as the tests for geochemical characterization, the proponent has not released most of its results	ANA's claim that methods in MEND (2009) are not being followed is false and has been responded to numerous times by Great Bear Resources. Geochemical information has been shared with ANA as far back as 2023 and most recently with the updated filed Closure Plan in November 2024 including static testing results for hundreds of samples including mine rock and overburden and kinetic testing results for mine rock and overburden.
D3	As well, the proponent plans to use incorrect analytical methods in the proposed studies which are flawed and "will underestimate the amount of mercury in Great Bear mined materials including the walls of underground workings and pits, waste rock, overburden, soil, and tailings." Dr. Morin opines that the proposed methods are "not appropriate, reliable, and safe for the Mercury Study." He adds that the proposed groundwater modelling is similarly unreliable. Dr. Morin concludes that he expects that the proponent will underestimate the important geochemical input and groundwater flow leaving its Gear Bear site which is "critical for a reliable outcome from the proposed Mercury Study."	As outlined in Comment M3 of this document, ANA indicates that mercury should be measured by a "total digestion" method. ANA also indicates that "Kinross fails to explain to non-technical readers that this will underestimate the amount of mercury in Great Bear mined materials including the walls of underground workings and pits, waste rock, overburden, soil, and tailings". ANA is indicating that a method known to underestimate solid phase mercury concentrations should be utilized for the Project. Total digestion methods involve the use of several strong acids and high temperature heating of a sample to completely dissolve the material. Due to the chemical properties of mercury, it can be volatilized under these conditions, which can result in erroneously low mercury concentrations being reported for a given sample. As such, analytical laboratories do not recommend the use of this procedure for solid phase mercury analysis.

#	Comments	Great Bear Resources Response
		The Project has utilized the aqua regia digest method to measure mercury. Mercury is not volatilized by this method and can thus be accurately measured. Please see responses N1 to N5 for a discussion of groundwater modelling.
D4	The proponent should not proceed with the Study Plan until there is high quality ML-ARD data and baseline data over multiple years for the model, and a credible monitoring plan in place. This must also be completed before the proponent proceeds with further activities that could cause potential impacts, including impacts to baseline data, for example, AEX construction, road and trail building, etc.	Baseline geochemical data for the Project has been collected since 2022. Ongoing geochemical characterization programs and water quality modelling is following industry standard approaches for mining projects in Ontario. Models will be verified and validated through continuing laboratory and field programs as well as on-site monitoring.
E. The assimilative capacity of the receiving waters as a mitigation strategy for excess sulphate loading is not supported by the available data.		
E1	The proponent continues to present a mitigation strategy that involves "discharging treated effluent to a large receiving watercourse (Chukuni River) that has a high oxygenation level and high assimilative capacity." Our experts have commented on this "strategy" in previous submissions, explaining that this presents an erroneous understanding of methylation in aquatic environments. Dr. Branfireun responds in detail in his enclosed report. Dr. Branfireun concludes that: The strategies for treating effluent to be discharged to the Chukuni River do not target sulphate, and sulphate production from overburden and waste rock are likely to be greater than the proponent states. The proponent's assessment of the watercourse's assimilative capacity is inadequate as the proponent uses the average of	Much of the content of this comment is specific to the ECA ISW application for the Advanced Exploration Program and its supporting technical studies. They are not applicable and do not accurately reflect the content, intent, or proposed methodology of the Mercury Study Plan or the effects assessment regulatory process for a proposed mining Project in Ontario. The effects assessment for the proposed Project is underway, and mitigation and treatment strategies will be informed based on outcomes of baseline studies and predictive modeling, as is standard practice and supports the development of appropriately targeted and effective mitigation measures. Final effluent criteria will be informed by the content and conclusions of the effects assessment, but are established through the provincial permitting process subsequent to the effects assessment, as is the regulatory environment in Ontario. The assertion that sulphate treatment is not being considered is incorrect. Great Bear is actively evaluating water treatment options, including strategies to manage sulphate concentration, in alignment with regulatory requirements, best practices and feedback received from communities.

#	Comments	Great Bear Resources Response
	entire daily discharge records for all of their dilution scenarios. There are potentially dire sulphate concentrations/volumes that could arise as a result of low flows combined with higher than stated effluent sulphate concentrations/volumes. The proponent relies on the high oxygenation level of the Chukuni River and does not consider the methylation potential of downstream waters, nor riparian areas and porewater, where this well-oxygenated river will deliver sulphate that may be many times in excess of background levels, in particular, to downstream mercury-sensitive lakes with high mercury methylation potential. As with other components of this project, the cumulative impacts of this project in the context of other past, present, and planned projects does not appear to have been considered. There are at least five other gold mining projects proposed or operating in this watershed, as well as a pulp mill, sawmill, dams, diversions, clearcut logging, and municipal waste. As well, the other mitigation measures described in the Study Plan are generally vague, unclear, and incomplete, and the list of potential effects is similarly incomplete and does not include potential effects from road and trail construction, site clearing, soil impacts, and water/dewatering, for example. There is insufficient information available for Grassy Narrows to adequately assess the proposed mitigation measures, and the information provided to date does not satisfy our experts that the proposed measures are effective and safe.	The Mercury Study Plan is not a stand alone Impact Statement. The claim that mitigation measures are vague and incomplete misrepresents the scope of the Mercury Study Plan and the level of detail already provided. The study plan outlines mitigation strategies that are available, being considered, and will be refined as supporting studies are progressed. Cumulative effects will be assessed in the Impact Statement consistent with the Tailored Impact Statement Guidelines and other guidance provided by the Impact Assessment Agency of Canada.

F. The proposed model that the proponent plans to use to predict changes in sulphate, mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish cannot technically deliver on those outcomes.		
F1	The Study Plan states that the proponent will rely on the GoldSim software modelling package to "simulate the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project." Our experts raise significant concerns with the GoldSim software, including its inability to be applied to an environmental mercury speciation scenario, and opine that additional information on the model is required before it can be assessed as an adequate model for the methylation studies.	GoldSim is a widely recognized tool for developing water quality models. GoldSim's application in simulating water volume, flow, and chemical species transport is well-established in environmental modeling, and is the industry standard for mining projects. However, it is important to clarify that while GoldSim is a valuable modeling tool for surface water, the accuracy and reliability of the model in predicting mercury and methylmercury concentrations will be driven primarily by data inputs and assumptions, rather than the specific software employed. In this regard, the surface water model developed to support the effects assessment and Mercury Study Plan will use site-specific empirical data and include clear identification of the interconnections between mercury, sulphate, and other relevant factors, underpinning the model. These interconnections will be grounded in findings from site-specific baseline studies, site-specific geochemical programs, analogue site data, and peer-reviewed scientific literature. The overall approach to the GoldSim model will thus reflect a strong empirical foundation and a comprehensive understanding of the relevant environmental processes. The findings of the surface water model will support subsequent bioaccumulation and aquatic food-web modelling
F2	Dr. Morin explains that mercury and sulphate predictions will only be generated at "nodes", the areas where the user-defined "conceptual boxes" connect. This means that the predictions will not simulate waterbodies in their environmental complexity, but simply represent the internal conditions that the proponent "chooses to assume, estimate, and simulate." It is particularly concerning that the Chukuni River will only be modeled at two "nodes", immediately above and below the	The node-based structure is an industry-standard method for predicting water quality changes across a study area and is commonly used in support effects assessment and approvals process of proposed mining project in Ontario. This approach provides a structured framework for evaluating potential water quality changes at key locations while maintaining a defensible balance between complexity and practicality. To clarify, the assessment for water quality will not be limited to node-based predictions alone. Hydrodynamic mixing modeling will be conducted to evaluate dilution and dispersion processes

#	Comments	Great Bear Resources Response
	property boundary. There are no "nodes" in Pakwash Lake nor further downstream where there are concerns of mercury methylation. There are also no nodes at a baseline site that is upstream from the impact of other local mines and therefore reflects uncontaminated conditions. Dr. Morin explains that "because of this "node" approach, important details like an initial dilution zone (a mixing zone) in the Chukuni River between Nodes CHK-1 and CHK-2 cannot be simulated in sufficient detail."	downstream of discharge within the Chukuni River, including the initial mixing zone. Additionally, food-web and bioaccumulation modeling will support the assessment of mercury, methylation and potential bioaccumulation processes. These analyses will provide a more comprehensive understanding of potential Project effects, beyond the individual assessment locations identified in the receiving environment (aka, nodes). Regarding currently proposed spatial coverage, the modeling framework is designed to be adaptive. The initial proposed placement of nodes was selected based on anticipated pathways of interaction between the Project and area watercourses. Additional locations can be incorporated. Water quality predictions will be generated for five areas of the Chukuni River: upstream and downstream of Project discharge, at the end of the mixing zone, downstream of the confluence of Dixie Creek and upstream of the confluence with Pakwash Lake. Modelling of Pakwash Lake will include downstream of the confluence of the Chukuni River, downstream of influences of inflows from inflows from Trout lake River, and at the Pakwash Lake outlet.
F3	Dr. Branfireun explains that GoldSim "does not appear to ever have been applied to an environmental mercury speciation scenario" and attributes this to the software's model which "cannot incorporate mechanistic sorption/desorption reactions along flow paths, the biomethylation process, nor the complex interaction between mercury and sulphate." Dr. Branfireun concludes that, as a result, "the model proposed can never be successfully applied in the manner that is proposed. […] A mass balance model *cannot* by definition incorporate mechanistically the input and removal processes for mercury, and *cannot* address the biogeochemical aspects of mercury methylation across the landscape which are at the root of the potential impacts associated with the Great Bear proposal."	GoldSim is a widely recognized tool for developing water quality models. GoldSim's application in simulating water volume, flow, and chemical species transport is well-established in environmental modeling, and is the industry standard for mining projects. However, it is important clarify that the stimulated processes and reactions represented in the model are user defined, rather than being defined by the specific software employed. In this regard, as appropriate, the GoldSim model can include data inputs regarding mercury speciation and user-defined calculations and assumptions regarding sorption/desorption reactions along flow paths etc. The surface water model developed to support the effects assessment and Mercury Study Plan will use site-specific empirical data and include clear identification of the interconnections between mercury, sulphate, and other relevant factors, underpinning the model. These interconnections will be grounded in findings from site-specific baseline studies, site-specific geochemical programs, analogue site data, and peer-reviewed scientific literature. The overall approach to the GoldSim model will thus reflect a strong empirical foundation and a comprehensive understanding of the relevant

#	Comments	Great Bear Resources Response
		environmental processes. The findings of the surface water model will support subsequent bioaccumulation and aquatic food-web modelling.
F4	The Study Plan, and its model, also appear to ignore a number of parameters beyond THg, meHg, and sulphate which can impact methylation dynamics including DOC, light penetration, temperature, pH, and other parameters.	These parameters will be considered in the Mercury Study Plan.
F5	We are not satisfied that the GoldSim software proposed is appropriate or technically able to apply to the circumstances and produce a useful prediction. We are concerned that the technical limitations of the software, as well as the manner in which the proponent intends to use the software, will not produce reliable, accurate, or useful predictions. Our concerns are heightened given the ongoing data quality problems in relation to the Great Bear Project – flawed data will lead to flawed results, regardless of the software chosen.	Please see responses above regarding proposed modelling approach, noting that ANA have not suggested an alternative software that they believe is appropriate or technically appropriate for discussion. The overall approach to the GoldSim and bioaccumulation model is comprehensive and sufficient to support the effects assessment. The aquatic food web modelling will be based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Appropriate mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling.
G. Conclusions		
G1	Dr. Branfireun concludes in his report: "We have a water quality model that is not capable of predicting mercury biogeochemical processes, that is dependent on background data and proposed monitoring that is insufficient. The outcome will be the inevitable future conclusion by the Proponent that	We strongly disagree with Dr. Branfireun's statement, and assert that as it misrepresents both the modeling approach and the broader effects assessment approach being taken for the Project, using industry-standard approaches, consistent with guidance provided by the Impact Assessment Agency of Canada. The proposed water quality modeling framework meets regulatory requirements and aligns with industry best practices for assessing potential Project-related effects. Contrary to the assertion that the

#	Comments	Great Bear Resources Response
	the combination has led to an inability to adequately predict changes in methylmercury concentrations in fish because of 'uncertainties' in GoldSim output, and "unforeseen complexities" in coupling abiotic and biotic compartments. The reality is that these uncertainties and complexities are completely foreseeable as outlined here. […] I conclude that the TISG's requirement that the Proponent provide a detailed and robust analysis on the potential for project contributions to methylmercury production in downstream watersheds has not been met based on the information provided in the Mercury Plan."	model is incapable of predicting mercury biogeochemical processes, the Mercury Study Plan proposes to incorporate multiple lines of evidence, including food-web modeling, to assess methylmercury production and bioaccumulation. The integration of hydrodynamic mixing modeling further strengthens the assessment by addressing spatial and temporal variability in the receiving environment. As presented in Great Bear Responses to comments above, the claim that background data and proposed monitoring are insufficient is unfounded. Baseline studies are comprehensive and have been designed to characterize existing conditions comprehensively, including key drivers of mercury methylation. The suggestion that uncertainties will inevitably prevent an adequate assessment is speculative and incorrect. While all environmental models have inherent uncertainties, the proposed approach employs standard methodologies, supported by site-specific data, used in regulatory approvals across the mining sector. These methodologies are well-established for evaluating potential project effects. The effects assessment and supporting modelling studies have been designed to be rigorous, transparent, and to provide meaningful predictions that support regulatory decision-making for a Project at this stage in the approvals process. We disagree with Dr. Branfireun's biased and unfounded claim that the proposed approach will not provide a detailed and robust analysis. Assertions to the contrary disregard the structured and methodical approach being undertaken to assess potential effects comprehensively. Dr. Branfireun asserts that the Mercury Study Plan lacks sufficient detail regarding the potential for project contributions to methylmercury production. However, no specific advice or technical guidance has been provided to clarify what would constitute an adequate level of analysis. We are fully open to considering input into the plan, but general criticisms without actionable suggestions do not help advance the discussion. We encourage the provision of clear, solution-oriented feedback so that we can meaningfully address any outstanding concerns.

#	Comments	Great Bear Resources Response
G2	In light of our experts' opinions, we are concerned with this Study Plan and require additional time to complete a fulsome review and engage with our experts in a more in depth manner, and to engage with our other experts and our community. We reiterate our request for a 90-day extension to provide comments. It is not prudent nor rational to proceed with a Mercury Study which is built on erroneous, incomplete, and inaccurate data and which uses flawed methodology that is unable to adequately address the biogeochemical aspects of mercury methylation across the landscape as required. We expect that the proponent will not move forward with this Study Plan, the proposed studies, or any additional work on the site that may cause adverse effects prior to receiving and meaningfully integrating our comments.	Great Bear Resources, remains committed to respectful, transparent, and inclusive engagement with Indigenous Nations, the public, and regulators throughout the development of the Great Bear Project.

#	Comments	Great Bear Resources Response
H. Opinion 1: **The selective reliance on achieving on and off site water quality that complies with water quality guidelines (CCME) in inadequate and inappropriate when considering mercury and methylmercury in water, and methylmercury uptake by biota.**		
H1	Disregarding the fact that the authors of the report surprisingly misstate the CCME guideline for methylmercury (it is 4 ng/L not 0.04, although 0.04 would be more scientifically justifiable), the statement that the data from the proposed project will be "compared against" any criteria is meaningless, because one may compare an apple to an orange; no intent, threshold, nor trigger value is indicated or even implied by this language. Despite quoting the more reasonable US EPA criterion of 0.05 ng/L methylmercury for the protection of fish-eating wildlife, prior documents submitted for this project indicate clearly that the Proponent intends (and has been approved by the Ontario MECP) to apply the CCME guideline the project from a compliance standpoint, so the reader should presume that the CCME values are the regulatory thresholds being applied by this Mercury Plan, rather than merely comparisons. As I have stated in prior opinions, there is no other way to characterize the CCME guideline values for mercury and methylmercury as anything but useless for the protection of fish consumers, and even if discharges or indirect effects were a fraction of these guideline limits there would be significant potential for downstream impairments of aquatic resources. For	Regardless of the water quality guidelines applied for comparison purposes, the HHERA will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish and consumption rates for members of the local communities. Fish concentrations will be predicted based on a food web model that takes into account the potential for bioaccumulation. The aquatic food web modelling will be based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Appropriate mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling.

#	Comments	Great Bear Resources Response
	example, the CCME Criterion for (Total) mercury is 26 ng/L, which is a value (developed from a 1991 protocol) for the **direct** protection of aquatic life. Despite being profoundly outdated, the CCME document provides valuable commentary that is all too frequently ignored when setting regulatory criteria based on this single value, including "*The protocol **does not** address exposure through **food or bioaccumulation** to higher trophic levels*", and "*if the ultimate management objective for mercury is to protect high trophic level aquatic life and/or those wildlife that prey on aquatic life, **more stringent site-specific application** of these water quality guidelines may be necessary*" (CCME, 2003, p.2; **emphasis mine**).	
H2	Although the Province of Ontario is silent on the issue of any other water quality guidelines for mercury, other jurisdictions have been more engaged with revising their mercury and methylmercury based on best available science at the time. British Columbia explicitly acknowledges the limitations of the CCMEs guidelines, stating "It should be noted that the CCME (2000) in developing guidelines for fresh and marine waters did not consider bioaccumulation effects per se, but based their guidelines on **chronic toxicity**. They caution that the guidelines that they have developed 'may not protect wildlife that consume aquatic life'." (British Columbia Ministry of Environment and Lands, 2001; emphasis mine). We may reasonably extend the statement about consumers of aquatic life to humans. Despite the document being nearly as old as the original CCME guidance, BC takes	As stated above, to support the overall Project, the Mercury Study Plan will incorporate multiple lines of evidence, including food-web modeling, to assess methylmercury production and bioaccumulation. As stated above, regardless of the water quality guidelines applied for comparison purposes, the HHERA will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish and appropriate consumption rates for members of the local communities. Fish concentrations will be predicted based on a food web model that takes into account the potential for bioaccumulation. The aquatic food web modelling will be based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Appropriate mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling. The same food web model will be used to predict mercury and methylmercury concentrations in smaller fish that would be consumed by piscivores.

#	Comments	Great Bear Resources Response
	the interesting approach of defining the water quality guideline to protect wildlife for total mercury by scaling it as a function of the percentage of total mercury that is methylmercury, acknowledging that methylmercury is the only form of mercury that bioaccumulates and biomagnifies in wildlife. Their Table 5 indicates that only in environments where methylmercury is largely not being formed would the CCME guideline of 26 ng/L for total mercury be remotely reasonable for fish consumers to be protected. In environments where methylmercury makes up an increasing fraction of total mercury, the allowable amount of total mercury decreases proportionally with the %methylmercury in the system. At 8% of total mercury as methylmercury, the guideline for total mercury is 1.25 ng/L. Even at 8% methylmercury the BC guideline total mercury value is below the detection limit of the technique that the Proponent declares adequate for the purposes of monitoring (DL of ~ 5 ng/L). The Proponent states in this document (as I provided to them in prior submissions) that that % methylmercury in surface waters of the proposed project can exceed 14% (using their own sparse data), translating to a guideline concentration of a mere 0.72 ng/L for the protection of wildlife consuming aquatic life. Despite the BC document being nearly 25 years old, the rationale for their mercury criteria is logical, and recognize the fact that even low levels of mercury in the environment can bioaccumulate and biomagnify to hazardous levels for fish consumers if the landscape has high methylmercury production potential. It is clear that current conditions in surface waters in the project area already exceed this criteria, meaning that **any** cumulative effect would be in exceedance of BC criteria for mercury in freshwater.	

#	Comments	Great Bear Resources Response
H3	I find it impossible to accept any generalized guideline for mercury or methylmercury in aquatic environments, and instead advise site specific assessment for appropriate threshold levels (which the CCME also explicitly does in their 2003 document, but never seems to be considered). An acceptance of this project mercury plan adhering to the CCME guidance for mercury and methylmercury threshold concentrations for direct and indirect effects is effectively a license to impair downstream resources given the low concentrations of mercury identified by the Proponent through limited baseline sampling. Site specific criterion for mercury and methylmercury must be required here, and derived from **appropriate** baseline data – scant little of which currently exist (see Opinion 2).	Regulation of mining projects is purposefully guided by federal and provincial, law and regulatory guidance that have stood the test of time, and reflect and balance the technical knowledge of many qualified professionals. Regardless of the water quality guidelines applied for comparison purposes, the HHERA will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish and appropriate consumption rates for members of the local communities. Fish concentrations will be predicted based on a food web model that takes into account the potential for bioaccumulation. The aquatic food web modelling will be based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Appropriate mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling.
I. Opinion 2: **The background data collected as part of the baseline studies for this project are largely erroneous or their interpretation is flawed, rendering them neither comprehensive nor sufficient to detect whether the project will have measurable impacts on fish mercury levels in the future.**		
I1	In the context of the protection of fish consumers, nearly all of the background data for total mercury are useless and stated incorrectly. All of the "data" that are reported in Table 2.10 of "Attachment 4 - Surface and Groundwater Technical Supporting Document" (March 2024) for total mercury are not data at all, but the reporting detection limits of the contract laboratory The background mercury data in water (with the exception of the handful of appropriate trace mercury and methylmercury analyses that were conducted by Flett Research) **is incorrect**. The data provided for mercury **are not data** – they are detection limits of the inappropriate technique used to do	Much of the content of this comment is specific to the ECA ISW application for the Advanced Exploration Program and its supporting technical studies. They are not applicable and do not accurately reflect the content, intent, or proposed methodology of the Mercury Study Plan or the effects assessment regulatory process for a proposed mining Project in Ontario. These concerns were previously raised by Grassy Narrows in October 2024, and have most recently been addressed in the October 25, 2024 memorandum "*Response to ANA Letter Concerning Great Bear Project AEX ECA ISW Application and Expected Impacts to the Chukuni River*". Key points are as follows:

#	Comments	Great Bear Resources Response
	element scans by inductively coupled plasma – mass spectrometry (ICP- MS). ICP-MS in a standard configuration cannot generate data for mercury with appropriate detection limits (despite the Proponent's assertion to the contrary in the Mercury Plan). Moreover, the Proponent treats these detection limit placeholders as data – **these are not data.** If the contract laboratory reported these values as data, then they are not operating in compliance with ISO 17025 protocols. If the Proponent substituted detection limits for samples reported to be below the detection limit by the contract lab, then this is not correct procedure and should be stated as such. In both cases, a serious lack of oversight and understanding of analytical results is clear as **these are not data**. There is also insufficient data for methylmercury in surface water as this critical parameter was only measured sparsely as part of the baseline monitoring program. As a result, there is virtually no background data for mercury in surface waters for the project area, nor is there sufficient monitoring in the proposed plan because the appropriate trace mercury and methylmercury monitoring is only proposed at select locations and at a frequency that is insufficient to detect change over time, and with highly inappropriate threshold levels that are orders of magnitude above the levels at which adverse effects will occur.	*"The water quality laboratory analyses have been conducted using industry-approved methods at accredited laboratories (Canadian Association for Laboratory Accreditation). It is important to clarify that while ICP-MS has been used for total metal scans, it has not been employed for mercury quantification since 2021 such that detection limits of ongoing analyses are much lower. Starting in 2022, sulphate and mercury monitoring on the Chukuni River has included the following analyses:* • *Methylmercury by Distillation, Aqueous Ethylation, Purge and Trap, and Cold Vapor Atomic Florescence Spectroscopy (CVAFS) at specialized laboratories[c] with reported detection limits of approximately 0.0035 ng/L* • *Ultra-low mercury by Oxidation, Purge, and Trap, and CVAFS at specialized laboratories with reported detection limits of approximately 0.04 ng/L* • *Standard mercury by Cold Vapor Atomic Absorption Spectroscopy (CVASS) with reported detection limits of approximately 5 ng/L* • *Sulphate (method E235.S04) with reported detection limits of approximately 0.3 mg/L* *The analytical methods used and the reported detection limits (DL) are sufficiently sensitive to characterize the existing water quality of the Chukuni River. Dr. Branfireun correctly noted that analytical results below the reported DL were retained in the water quality database and included in the statistical summaries presented in the Application. This approach is consistent with established guidance on environmental data handling (Environment and Climate Change Canada, 2014; Environmental Protection Agency, 1990), reflects industry standards and regulator expectations, and is appropriate to support baseline database creation.* *For sulphate concentrations, it is noted by Dr. Branfireun that there is variation in reported water quality data over the period of record, such that sulphate data is not useful. Water quality in natural systems is inherently dynamic and can fluctuate even over short periods due to a range of*

#	Comments	Great Bear Resources Response
		environmental factors, such as precipitation, runoff, temperature changes, and natural heterogeneity in ice cover. The variation identified by Dr. Branfireun of 7 mg/L sulphate on 2022-December-15 and 1 mg/L sulphate on 2022-December-19, as being erroneous, is consistent with expected natural variability and does not undermine the reliability of the overall dataset, which includes hundreds of data points. Such fluctuations are typical in natural aquatic environments. The claim that virtually no background data is unfounded and inaccurate. Data collection has been designed to be extensive and appropriate to inform the effects assessment, and encompass a comprehensive network of sites strategically selected to capture and characterize spatial and temporal variations.
I2	Further investigation into the baseline monitoring data provided in Attachment 4 of the AEX- ECA application which contains all of the background data cited by the Proponent in the Mercury Plan also reveals that the **concentrations reported for sulphate were also erroneous** up until May of 2023 when the Proponent either changed analytical methods or laboratories, or incorrect instrument operation was corrected. From 2021-06-03 to 2023-03-30, we find data that are reported with no precision (i.e. no decimal place) and spuriously range from values of 1 to 11. I know of no analytical technique that would report concentrations like this (we see similarly erroneous data for parameters such as Chloride, TSS, TDS). The clearest evidence to me that this data is no better than random is the value of 7 mg/l on 2022-12-15, followed by a value of 1 mg/L four days later on 2022-12-19. Given that there was no appreciable change in river flow over this time, **these data are erroneous and cannot be used**. There is similar randomness in other parameters. The fact that the average concentrations that are reported directly in the Appendix are	Much of the content of this comment is specific to the ECA ISW application for the Advanced Exploration Program, and its supporting technical studies. So being, the comment does not accurately reflect the content, intent, or proposed methodology of the Mercury Study Plan or the effects assessment regulatory process for a proposed mining Project in Ontario. These specific concerns were raised by Grassy Narrows in 2024, and have most recently been addressed in the October 25, 2024 memorandum "*Response to ANA Letter Concerning Great Bear Project AEX ECA ISW Application and Expected Impacts to the Chukuni River*". #	Comments	Great Bear Resources Response
I3	Notably, the data quality changes substantially in May 2023, with two decimal place precision and a much more realistic range of concentrations (4.18 – 6.30 mg/L). Other parameters also show this step change in data quality. There was obviously a change in technique or in the contract laboratory being used that was not documented, which is contrary to best practices at the very least. Other variables reported are also suspect up until this date as many of the physical parameters (e.g. TDS, TSS) and nutrient data ($N0_2$), contain inexplicable values, change in quality, or are dropped completely (e.g. NO_3-$N0_4$-T). The failure to note and censor these erroneous data is inexplicable – to use them to calculate descriptive statistics is inexcusable. For these variables (including sulphate) there are only 8-9 usable data points for all of the stations reported (including the Chukuni River). The Mercury Plan makes reference to comprehensive background data about mercury and sulphate that will inform modelling efforts and trigger undefined actions should they change. One cannot numerically model concentrations of "below the detection limit". The reality is that the background data is neither "comprehensive" nor "sufficient" by any reasonable definition, and the approval of a Mercury Plan such as this is license to both proceed blind with respect to the site specific mercury conditions, as well as condone the continued	The analytical methods used and the reported detection limits (DL) are sufficiently sensitive to characterize the existing water quality of the Chukuni River. This approach is consistent with established guidance on environmental data handling (Environment and Climate Change Canada, 2014; Environmental Protection Agency, 1990), reflects industry standards and regulator expectations, and is appropriate to support baseline database creation.* *For sulphate concentrations, it is noted by Dr. Branfireun that there is variation in reported water quality data over the period of record, such that sulphate data is not useful. Water quality in natural systems is inherently dynamic and can fluctuate even over short periods due to a range of environmental factors, such as precipitation, runoff, temperature changes, and natural heterogeneity in ice cover. The variation identified by Dr. Branfireun of 7 mg/L sulphate on 2022-December-15 and 1 mg/L sulphate on 2022-December-19, as being erroneous, is consistent with expected natural variability and does not undermine the reliability of the overall dataset, which includes*
J. Opinion 3: **The assimilative capacity of the receiving waters (Chukuni River) as a mitigation strategy for excess sulphate loading is not supported by available data. As this is the only measure that has been proposed to address the indirect downstream effect of sulphate-related methylmercury production, there is no evidence that other adverse downstream effects can be avoided.**		
J1	**Treated effluent:** Indeed the Proponent has outlined strategies for treating effluent to be discharged to the Chukuni River, however none of the treatment technologies proposed target sulphate at all. Sulphate production from overburden and waste rock could be substantially greater than the Proponent states. Given that groundwater contributes nearly 80% of the total water outflows, 25% of groundwater samples (75th percentile) from many locations in the project area had	The mercury study plan was prepared for the Project, yet this comment like many others, appears to pertain to the AEX Program. The reviewer appears to be confusing water quality estimates prepared for the AEX with water quality estimates currently in preparation for the overall Project. Regarding the AEX water quality estimates: • Geochemical testing indicates that overburden is non-potentially acid generating (NPAG) (average NPR = 34) with very low concentrations of sulphur. Of the 116 overburden samples tested,

#	Comments	Great Bear Resources Response
	sulphate concentrations well in excess of 10 mg/L (Appendix B, Table 3 AEX- ECA Application), and the water treatment technology outlined by the Proponent has no capacity to remove sulphate, it would seem that the Proponent's 'expected' case of 10 mg/L sulphate is not just unlikely, but nearly impossible to achieve without even considering the potential for additional sulphate sources due to operations. Indeed without any additional treatment the Proponents 'extreme' case is likely a gross underestimate. With only gypsum saturation ultimately controlling sulphate solubility, sulphate concentrations in the range of 1000-1500 mg/L may be expected and are in fact, typical of many mine sites with oxidizing sulphide minerals like pyrite.	approximately half of the samples had below detection limit sulphur concentrations (<0.005% or 0.01%). When detectable, sulphur concentrations ranged from 0.006% to 0.11%. High concentrations of sulphate from overburden, as claimed by ANA, are not supported by the geochemical test results. • The bulk of the rock generated as part of the AEX is expected to be NPAG and comprise the basalt lithology. Samples of basalt generally have a low sulphur content with a median sulphur content of 0.2%. Sulphate release from the rock was accounted for in water quality estimates for the AEX utilizing industry standard data (e.g., humidity cell tests) for drill core samples representing the rock to be excavated as part of the AEX Program. • The claim that sulphate concentrations in groundwater are well in excess of 10 mg/L is false. The median and average sulphate concentrations in monitoring wells is 4.9 mg/L and 8.5 mg/L, respectively. Approximately 75 percent of the samples have sulphate concentrations ≤10 mg/L. The 95th percentile sulphate concentration is 22 mg/L. This includes data for 74 wells comprising 241 datapoints. Monitoring wells proximal to the AEX portal area have even lower range of sulphate concentrations; the 95th percentile sulphate concentration in those wells is 13 mg/L. Water quality estimates for the overall Project for mine operations and closure are underway. Sulphate is a model parameter and the results of these estimates will be used to identify strategies to manage sulphate in the effluent discharge, if required.
J2	**Large watercourse:** This is of course a relative statement however a 20-year median annual discharge of 26.5 m^3/s is objectively a substantial flow. However as I have outlined in prior memos (Branfireun Review of Kinross Response to ANA Memo concerning Great Bear Project AEX ECA Application, August 1, 2024; October 7, 2024), median or mean statistics do not tell the whole story about assimilative capacity, despite the Proponent utilizing the simple numerical average of the entire daily discharge record (which upward biases the value)	The mercury study plan was prepared for the Project, yet this comment like many others, appears to pertain to the AEX Program. The reviewer appears to be confusing water balance estimates prepared for the AEX Program with water balances currently in preparation for the overall Project. Data inputs, assumptions and results of the water balance modelling to support the overall Project, including discharge volume relative to receiving environment flows, will be provided in the effects assessment. Water balance modelling will include evaluation of extreme wet and extreme dry periods as well as climate change scenarios, in addition to average conditions, as to elevate lower ranges of flow.

#	Comments	Great Bear Resources Response
	for all of their dilution scenarios presented in prior submissions to justify assimilative capacity. In the context of dilution of an environmentally relevant chemical, it is more relevant and protective to explore the lower ranges of flow, since it is at these levels that the river has less assimilative capacity and adverse effects are more likely. The 20-year average 25th percentile value is 14.2 m^3/s, meaning that for a full quarter of the year (which would include the relevant summer low flows when biogeochemical activity including methylation would be the highest), flows in the river are equal to or less than this value. The 20-year average minimum flows are only 5.7 m^3/s; more than 5 times lower than the discharge value that the Proponent used to calculate dilution. I argue that this is a more appropriate 'extreme' case discharge value to use, however it is notable that **the record contains a period of zero flow conditions in 2011 – a condition under which effluent discharge would make up 100% of river flow and would be completely undiluted (i.e. the river has zero assimilative capacity)**. 2023 was among the lowest flow years in the last 20, and the central tendency of the river discharge over that period is toward lower, and less variable flow. If the 2023 flow statistics (median, 25th percentile, and minimum flows of 13.5, 6.6 and 3.1 m^3/s are reflective of future drier conditions driven by climate change, then the use of a single value of average flow that is 10x greater than this low flow condition to calculate effluent dilution and demonstrate assimilative capacity is clearly not protective by any definition.	This comment regarding the AEX Program, and concerns raised regarding hydrological data handling was previously addressed in the following memorandum "*October 2024. Discharge to the Chukuni River, Great Bear AEX ECA ISW Application*". Key points of discussion in this regard were as follows: "The Chukuni River is a regulated system, with flow controlled by the Snowshoe Rapids Dam. Water levels and flow releases at the dam are managed by the Ministry of Natural Resources (MNR).To support calculation of flow statistics in the Application, data available from the 63-year record (not the last 20 years) were used from Water Survey of Canada (WSC) flow gauge located on the Chukuni River near Ear Falls Station (gauge ID 05QC001). As noted in the ECA ISW Application for AEX, the period of record for this gauge includes various types of development in upstream watershed, as well as construction and modification of the Snowshoe Rapids Dam and its operating rules. The period of record was screened to remove low flow periods influenced by significant construction activities at the dam, based on WSC records and MNR documentation, including the period of zero flows in 2011, when the control structure was being repaired to support accurate forecasting of future conditions.

#	Comments	Great Bear Resources Response
J3	**High oxygenation level:** The Proponent has frequently made the argument that oxygenated waters in the receiving reach of the Chukuni River preclude negative effects of sulphate addition because sulphate reduction would not occur. This statement is misleading, as I could visit the most methylmercury contaminated lake in Ontario (Clay Lake) in August, measure surface water oxygen levels and declare it oxygenated. This would be ignoring the anoxic bottom waters and sediments where very high levels of methylmercury are formed. Of course, rivers do not stratify but it is well documented that they can have anaerobic sediments, biofilms and hyporheic zones where sulphate reduction and methylation can occur (despite having a well-mixed water column above). The biogeochemical status of the immediate receiving river reach is actually not the biggest issue here, it is the methylation potential of downstream waters where this well-oxygenated river will deliver sulphate that may be many times in excess of background levels. Pakwash Lake is the first lake downstream of the proposed effluent discharge, and already has **five** fish species that have restricted consumption advisories due to mercury contamination (https://www.ontario.ca/page/fish-consumption-report?id=50459330) indicating that any further loading of methylmercury, or enhancement of the methylating process either in the lake or upstream would amplify an existing environmental degradation. Whether the fish species with tissue mercury exceedances in Pakwash Lake immediately downstream of the proposed operation derive their methylmercury from Chukuni riverbank	The Mercury Study Plan was developed for the overall Project; the reviewer appears to be referencing technical supporting studies for the Advanced Exploration Program which is not appropriate. So being, the comment does not accurately reflect the content, intent, or proposed methodology of the Mercury Study Plan or the effects assessment regulatory process for a proposed mining Project in Ontario. The Chukuni River is a high-flow, turbulent watercourse with oxygen saturation throughout the water column. Comparing this dynamic environment to the stratified basin of Clay Lake, where hypolimnetic oxygen levels are low such that methylation processes are more likely supported, is misleading. To support the overall Project, the Mercury Study Plan will incorporate multiple lines of evidence, including food-web modeling, to assess methylmercury production and bioaccumulation, including downstream in Pakwash Lake where deep-basin conditions may support presence of anoxic bottom waters and sediments. The integration of hydrodynamic mixing modeling further strengthens the assessment by addressing spatial and temporal variability in the receiving environment. The proposed water quality modeling framework meets regulatory requirements and aligns with industry best practices for assessing potential Project-related effects. Regardless of the water quality guidelines applied for comparison purposes, the HHERA will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish and appropriate consumption rates for members of the local communities. Fish concentrations will be predicted based on a food web model that takes into account the potential for bioaccumulation. The aquatic food web modelling will be based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Appropriate mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling.

#	Comments	Great Bear Resources Response
	wetlands, river littoral sediments, biofilms or periphyton, anoxic profundal lake sediments, or anoxic hypolimnetic waters during stratification is actually irrelevant – methylmercury is produced in the aquatic environment because it is found in fish in downstream receiving waters and it is dependent on the activity of sulphate-reducing bacteria, which are dependent on available sulphate. To have that many species with mercury consumption advisories confirms that this is a mercury sensitive environment with high mercury methylation potential.	
K. Opinion 4: **The model that the proponent indicates will be used to predict changes in mercury and methylmercury concentrations in downstream watersheds and assess the potential impact on mercury levels in fish (including assessment of bioaccumulation / bio- magnification pathways) cannot technically deliver any of these outcomes.**		
K1	In the Great Bear Project Mercury Plan Section 3.4.3, the Proponent states that the GoldSim software modelling package will be used to "stimulate ***(sic)*** the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project." Without substantiation, they go on to state that "GoldSim has been extensively and successfully applied to simulate complex water resource management, mining operation, contaminant transport, and waste management projects and represents a robust industry-standard modelling software." Although I do not disagree that GoldSim has been widely applied to various industry problems I cannot speak to its success. I can say that it does not appear to ever have been applied to an environmental mercury speciation scenario. There is a clear reason for this – GoldSim is fundamentally (even with its CT submodel) a non-reactive mass-balance	Please see response to question F1, F2 and F3.

#	Comments	Great Bear Resources Response
	model that cannot incorporate mechanistic sorption/desorption reactions along flowpaths, the biomethylation process, nor the complex interaction between mercury and sulphate. As such, the model proposed can never be successfully applied in the manner that is proposed. A mass balance model *cannot* by definition incorporate mechanistically the input and removal processes for mercury, and *cannot* address the biogeochemical aspects of mercury methylation across the landscape which are at the root of the potential impacts associated with the Great Bear proposal. The reason why mass balance models are used for solutes (and can work for solutes that are conservative in water) is because they are simple to apply quickly and require little parameterization (i.e. are inexpensive to implement). Indeed they can have value to evaluate simple "what if" scenarios. However, being cheaper and easier to use is not sufficient justification for taking a naïve approach to evaluating possible environmental risks in a region of extreme mercury sensitivity, when much more defensible approaches exist, including models for watershed-steam mercury dynamics. On page 17 of the Mercury Plan, the authors state that GoldSim is used because it provides "a clear description and rationale for model input parameters and assumptions." I have seen this language used in other cases that I have opined about, with the implication being that GoldSim is somehow MORE clear in its description and rationale of input parameters and assumptions than other models (i.e. superior). This seems to be popular but baseless justification, as it implies that it is somehow more transparent than other model frameworks.	

#	Comments	Great Bear Resources Response
	The statement that the mass balance models like GoldSim are transparent with respect to data inputs is true, in that it is true that *any* model is transparent with respect to data inputs because one must know what the data inputs are in order to run the model (a non sequitur). What is also true of any model is the adage of "garbage in, garbage out." The definition of input parameters and stated variables is always required in any model, as is the establishment of boundary conditions and mechanisms that reflect the best available science. In the case of the Great Bear Project, we have a virtual absence of useable data for baseline water quality (see above), which means that we are at a loss for values for the very input parameters that are required.	
K2	The Great Bear Project Mercury Plan reaches even farther by stating that "Results of GoldSim modelling for surface water and sediment quality, described above, will be used to forecast and assess potential effects on fish mercury concentrations in downstream watersheds. Both small and large-bodied fish will be considered in this assessment." My understanding of GoldSim is that it uses the sediment compartment to model water chemistry, not the other way around, so to suggest that GoldSim can be used predictably for the sediment compartment is unrealistic beyond simple mass transfer, despite the importance of the sediment compartment for net methylation. More problematic is the leap of faith between whatever output is provided by GoldSim and a prediction of methylmercury concentrations in biota. There is no evidence of any such effort being successfully reported in the public domain; if the Proponent has advanced the science in this area then I would welcome an opportunity to review their efforts in this regard	Goldsim model results for water quality will be used as inputs to food-web and bioaccumulation modelling. Please also see response to comments F1, F2 and F3. As described previously, the HHERA will assess human health risks from predicted changes to mercury and methylmercury concentrations based on measured and predicted changes in water and fish and appropriate consumption rates for members of the local communities. Fish concentrations will be will account the potential for bioaccumulation and biomagnification of methylmercury, based on empirical baseline data that has measured the mercury and methylmercury concentrations in herbivorous, insectivorous, and piscivorous fish and the supporting food web as well (i.e., invertebrates, zooplankton and periphyton). In addition, the empirical data includes measurements of mercury and routine parameters in sediment, porewater and surface water. Appropriate mathematical relationships will be constructed between the food web items to calculate concentration changes in the food web associated with concentration changes predicted in sediment/water quality modelling.

#	Comments	Great Bear Resources Response
	as it would mark a major breakthrough in modelling mercury biogeochemistry and biotic uptake. I suspect that this is not the case, since the means by which this is to be accomplished is apparently "changes in fish body burden mercury concentrations is considered to be the forecasted methylmercury concentration in the water column, as determined by the water quality model." I am not sure who "considered" this relationship, however it was not someone with a modest scientific understanding of the controls on fish tissue MeHg concentrations – such a simplistic forecasting relationship does not exist, and this is in addition to the fact that GoldSim cannot predict methylmercury concentrations in the first place.	
L. Other Errors, Omissions and Concluding Remarks		
L1	There are other problematic statements throughout the Mercury Plan that are used to downplay the potential impacts of the project do not align with scientific facts. The statement "For example, SRB-induced mercury methylation could occur in areas of organic soils peripheral to the rock stockpiles; however, methylmercury production beneath rock stockpiles can be limited by low temperatures at the base of the stockpiles which will inhibit SRB activity." is patently false given that the SRB can be quite active at temperatures just above freezing (e.g. Fortin et al., 2000).	As indicated, inhibition or lowering of sulphate reducing bacteria activity at lower temperatures is well documented in the scientific literature. • Hao, O.K. 2003. Sulphate Reducing Bacteria. #	Comments	Great Bear Resources Response
L2	We have all kinds of details on sample handling and Quality Assurance/Quality Control procedures in Section 2.2.1 that convey attention to detail and rigour, however a statement about sampling frequency is carefully worded so that the inadequacy of the water quality sampling is not apparent. *Baseline surface water quality sampling generally occurs monthly to characterize seasonal variability in water quality, providing flow is present and that the monitoring site can be safely accessed. (GBP Mercury Plan, p.5)* This statement fails to identify which solutes will be measured from this 'generally' monthly sampling, however in prior documents, the Proponent has clearly indicated that low detection level mercury and methylmercury sampling will only be done at only **half of the sampling sites**, and are only to be taken **quarterly (4 times per year)**. This low frequency of sampling of the only mercury data of utility is insufficient to statistically detect change until that change is so substantial that its effects would be irreversible. Since all of the other mercury sampling will be subject to an inappropriate analytical technique that will mostly return non-detects, the proposed monitoring programs are effectively designed to avoid change detection and I expanded on this in a prior memo (Branfireun to Esmonde, on Advanced Exploration Program (AEX) Environmental Compliance Approval - Industrial Sewage Works (ECA – ISW) July 5, 2024).	The statement is accurate and is not misleading. The ongoing sampling effort to support the effects assessment is monthly. Monthly sampling is conducted with flow is present, and site can be safely accessed. For most stations, this means data is collected 10 to 12 months out of the year. However, some small watercourses do not have flow in winter months (no flow, or frozen to bottom), such that samples cannot be collected. The final baseline report prepared to support the effects assessment will include the period of record (number of samples) for each station across the baseline data area. We disagree with the assertion that the proposed analytical methodology for water quality sampling for mercury is appropriate and will return mostly non-detect values. This specific concern was addressed most recently in Great Bear's October 2024 memorandum "*Response to ANA Letter Concerning Great Bear Project AEX ECA ISW Application and Expected Impacts to the Chukuni River*". Key points are as follows: *"The water quality laboratory analyses have been conducted using industry-approved methods at accredited laboratories (Canadian Association for Laboratory Accreditation). It is important to clarify that while ICP-MS has been used for total metal scans, it has not been employed for mercury quantification since 2021 such that detection limits of ongoing analyses are much lower. Starting in 2022, sulphate and mercury monitoring on the Chukuni River has included the following analyses:* • *Methylmercury by Distillation, Aqueous Ethylation, Purge and Trap, and Cold Vapor Atomic Florescence Spectroscopy (CVAFS) at specialized laboratories[f] with reported detection limits of approximately 0.0035 ng/L* • *Ultra-low mercury by Oxidation, Purge, and Trap, and CVAFS at specialized laboratories with reported detection limits of approximately 0.04 ng/L* • *Standard mercury by Cold Vapor Atomic Absorption Spectroscopy (CVASS) with reported detection limits of approximately 5 ng/L*

[f] Ultra low (ultra trace) analyses are offered by a limited number of specialized laboratories in Canada that use specialized analytical techniques and laboratory measures to avoid potential for cross contamination. Baseline ultra data for the AEX Program has been completed at Flett Research Ltd.

#	Comments	Great Bear Resources Response
		• *Sulphate (method E235.S04) with reported detection limits of approximately 0.3 mg/L* In response to Dr. Branfireun's inquiries about the adequacy monitoring the AEX monitoring Program, Great Bear Resources submitted the following response dated July 7, 2024: *The aquatics and surface monitoring programs for AEX Program have been developed in collaboration with the Ministry of the Environment, Conservation and Parks, and align with regulatory standards and expectations in Ontario. These programs are designed to proactively address / confirm potential effects and protect the receiving water throughout the AEX Program. The frequency and methodology of the aquatics sampling are in line with available regulatory guidance, including the Federal Metal and Dimond Mining Effluent Regulations (MDMER), and, together with the surface water quality program, are sufficient to detect changes, triggering management actions, before they reach a level that could cause adverse effects. With sufficient monitoring and ad-adaptive management programs in place, Kinross* [Great Bear Resources] *is confident in its ability to safe-guard surface waters and mitigate potential impacts.*
L3	Here, we see the assembly of a house of cards by the Proponent. We have a water quality model that is not capable of predicting mercury biogeochemical processes, and that is dependent on background data and proposed monitoring that is insufficient. The outcome will be the inevitable future conclusion by the Proponent that the combination has led to an inability to adequately predict changes in methylmercury concentrations in fish because of 'uncertainties' in GoldSim output, and 'unforeseen complexities' in coupling abiotic and biotic compartments. The reality is that these uncertainties and complexities are completely foreseeable as outlined here. The consideration of the December 2024 Mercury Plan as anything other than deficient will excuse the Proponent's future failure to predict the impact of the proposed development from a	We strongly disagree with Dr. Branfireun's biased characterization of the modeling approach, and assert this comment misrepresents the baseline dataset, modelling methodology, and rigor of the effects assessment as a regulatory process. The assertion that the water quality model is incapable of assessing mercury biogeochemical processes is incorrect. The assessment follows industry-standard practices and regulatory requirements, integrating multiple lines of evidence, including food-web modeling, to evaluate methylmercury production and bioaccumulation. Please also see responses to Comments F1, F2 and F3. The claim that the assessment relies on insufficient background data and monitoring is also incorrect. Extensive baseline studies have been conducted to characterize existing, pre-Project conditions, including key factors influencing mercury methylation. These studies provide site-specific empirical data and a defensible foundation for predictive modeling for a Project at this stage in development.

#	Comments	Great Bear Resources Response
	mercury perspective because of the appearance of due diligence at this stage of the process. I conclude that the TISG's requirement that the Proponent provide *a detailed and robust analysis on the potential for project contributions to methylmercury production in down- stream watersheds* has not been met based on the information provided in their Mercury Plan.	The suggestion that the assessment will inevitably fail due to 'uncertainties' or 'unforeseen complexities' is speculative and unfounded. While all environmental models have inherent uncertainties, the approach used here applies well-established methodologies to account for and manage these uncertainties effectively. The claim that the Mercury Plan does not meet the TISG's requirements is demonstrably false. The Plan provides a detailed and robust analysis of potential project contributions to methylmercury production, aligning with both anticipated regulatory expectations and established scientific principles. Assertions to the contrary disregard the structured, evidence-based approach being undertaken to assess the potential for Project effects and mitigate effects, and clearly show an anti-Project bias.

M. Geochemical Characterization		
M1	Subsection 3.4.1 explains the methods that will be used to predict the aqueous concentrations and solid-phase levels for dozens of potential contaminants at the Great Bear Project, including sulphate, ML-ARD, and water quality at near-neutral pH. This Study Plan states, "The sampling approach and testing methods for the geochemical investigations comply with ... guidance found within the Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND, 2009), which represents best practice and industry standard approaches and methodologies for ML/ARD sampling and characterization in Canada." Kinross committed to the same approach and testing for Advanced Exploration at the Great Bear Project years ago, but fails to follow guidance in this federal Prediction Manual of best practice and industry standards[g]. Where Kinross did follow some guidance and detected potential for significant water-	ANA's claim that methods in MEND (2009) are not being followed is false and has been responded to numerous times by Great Bear Resources. This comment is simply a repetition of an earlier comment from ANA regarding the analysis of neutralization potential content, which is not relevant to the analytical determination of mercury. Neutralization potential represents the capacity of a sample to buffer acidity. Neutralization potential originates from minerals such as carbonates or other silicates present in the sample. Several types of neutralization potential can be measured, including the carbonate neutralization potential (CarbNP, represented by fast reacting carbonates like calcite and dolomite) as well as a bulk neutralization potential (NP, represented by carbonates as well as some silicate minerals). In the absence of non-net neutralizing carbonates (which mineralogical testing indicates are not present in the Project materials), carbonate NP represents the most conservative indicator of a sample's neutralization potential. Use of carbonate NP assumes that only carbonate minerals are available for neutralization and does not rely on silicate minerals that may be present in a sample but can be slower to react and therefore not provide effective buffering capacity. As outlined in previous responses, the ARD potential for project materials was determined based on the NPR of the samples, calculated as CarbNP / MPA. This conservatively assumes that only carbonate minerals will provide neutralization potential, and that all of the sulphur present in the rock will

[g] MDAG. 2024. Review of Kinross Gold Responses to Grassy Narrows First Nation Concerns for Advanced Exploration, Concerning Metal Leaching, Acid Rock Drainage (ML-ARD), On-Site Contamination of Water, Fugitive Dust, and Hydrogeology in the ECA, PTTW, and Closure Plan Responses. Report for Grassy Narrows Lands Protection Team, dated September 5, 2024. 48 p.

#	Comments	Great Bear Resources Response
	quality degradation and ML-ARD, Kinross decided this serious potential was not relevant to its Great Bear site. Where Kinross admitted to not following the guidance and using a non-recommended procedure that was cheaper, Kinross' rationale was that the non-recommended procedure was mentioned in the federal Prediction Manual as not recommended and thus Kinross was indeed following the federal Prediction Manual.	generate acidity. CarbNP was based on total inorganic carbon, determined by HCl-Leco analysis, which is one of the approaches recommended by the MEND (2009) to determine carbonate NP. ANA is indicating that the Project should utilize bulk NP. This would potentially underestimate the ARD potential of the samples and would not be conservative.
M2	Kinross has committed to conducting many of the tests for geochemical characterization in this Subsection 3.4.1 as it did for Advanced Exploration at the Great Bear Project. However, as of early 2025, Kinross has not released most of the results for any geochemical testing.	Baseline geochemical programs are ongoing and additional results will be shared as part of the Impact Statement.
M3	Section 3.4.1 continues Kinross usage of the wrong analytical methods as it did for Advanced Exploration1. For example, Section 3.4.1 lists: "Solid phase elemental content analysis by aqua regia digestion and inductively coupled plasma-mass spectrometry scan" However, Kinross fails to explain to non-technical readers that this will underestimate the amount of mercury in Great Bear mined materials including the walls of underground workings and pits, waste rock, overburden, soil, and tailings. This is because is because "aqua regia digestion" dissolves and analyzes only part of the mercury and many other elements in Great Bear mine materials, leaving behind an undetected and unknown amount of additional mercury and other elements. This is not appropriate under conditions and pathways such as fugitive dust to the environment, local-scale acidic conditions, animal inhalation, and comparisons to crustal abundances,	Total digestion methods involve the use of several strong acids and high temperature heating of a sample to completely dissolve the material. Due to the chemical properties of mercury, it can be volatilized under these conditions, which can result in erroneously low mercury concentrations being reported for a given sample. As such, analytical laboratories do not recommend the use of this procedure for solid phase mercury analysis. The Project has utilized the aqua regia digest method to measure mercury. Mercury is not volatilized by this method and can thus be accurately measured. ANA is indicating that a method known to underestimate solid phase mercury concentrations should be utilized for the Project.

#	Comments	Great Bear Resources Response
	which require "total digestion" of all mercury in a sample rather than only part of the mercury from partial "aqua regia digestion". Thus, based on the listing of methods in Section 3.4.1 for mercury, sulphate, and other elements, it is easy to overlook or miss the facts that these proposed methods are not appropriate, reliable, and safe for the Mercury Study. Therefore, Grassy Narrows First Nation should understand that this Mercury Study Plan contains a program for Geochemical Characterization that matches that for Advanced Exploration, but Kinross has not been able to fulfill this program for Exploration to date after about two years of trying. Also, this geochemical characterization will use invalid and/or ambiguous methods that will underestimate the severity of mercury and sulphate issues at the Great Bear Project. As a result, I expect that Kinross will underestimate the important geochemical input that is critical for a reliable outcome from the proposed Mercury Study. If Kinross corrects the geochemical methods in the Mercury Study Plan to those appropriate to the Great Bear Project, then Advanced Exploration should be stopped because it is already based on invalid and/or ambiguous methods.	

N. Groundwater Modelling

General Note from Great Bear Resources

A groundwater model was not provided with the Mercury Study Plan, and we are assuming that the reviewer comments are drawn from their review of a model developed to assess dewatering impacts for the AEX Program. The Mercury Study Plan simply includes a generic description of a groundwater model. Nevertheless, we will attempt to address some of the reviewer's concerns based on their review of the AEX ramp model, recognizing that a modified version of this model will form part of the Impact Statement work. The reviewer has generally elected to provide vague and high-level commentary on groundwater modelling.

#	Comments	Great Bear Resources Response
N1	There are many errors in Kinross' modelling of groundwater flow at the Great Bear Project. Many reflect technical details that require relatively long explanations1. For example, groundwater modelling at the Great Bear Project apparently shows a high mound of free-standing groundwater above the land surface near Dixie Creek. This artificial and obviously wrongly modelling incorrectly restricts groundwater with mercury, sulphate, and other elements from travelling off the Great Bear site and into the surrounding environment around Dixie Creek.	The reviewer provides essentially three examples of where they believe the model is in error, 1) concerning artesian conditions, which is addressed below, 2) concerning the use of transient modelling, which is addressed in the responses to comments N2 to N5, and 3) a final concern about the use of an equivalent porous media approach. With respect to the presence of artesian conditions, a map of simulated groundwater levels has been provided in Figure 9.8 of the groundwater modelling report submitted in support of the PTTW application at the start of 2025. The reviewer's comments lack sufficient detail to identify the area of groundwater mounding above ground surface along Dixie Creek that they are referring to, however the comment provides an opportunity to correct a false impression that the reviewer appears to hold. Groundwater levels above ground surface are relatively common in low lying areas, and frequently manifest in the form of flowing (artesian) wells. Such flowing conditions are observed at the site near Dixie Creek in a number of exploration drillholes, therefore the model is not wrong and is consistent with site observations. Artesian conditions do require restrictions in groundwater flow to create pressure gradients, usually due to the presence of an aquitard between the creek and the well / aquifer. The aquitards present in the area of Dixie Creek include layers of low permeability overburden sediments and tight bedrock, which have been encountered during drilling at the site. We agree with the reviewer that the presence of aquitards would restrict interaction between Dixie Creek and groundwater, but as there is ample physical evidence to support their presence, their inclusion in the model is not an error.
N2	Perhaps the easiest error to understand with Kinross' groundwater modelling, for both Advanced Exploration and the Mercury Study Plan, is the difference between "transient" and "steady state" groundwater modelling. Similar to surface water and many other environmental processes like temperature and rainfall, subsurface groundwater flow can shift and change daily, seasonally, yearly, over decades, and even longer due to climate change. Thus, the earth's environment is inherently	We agree with the reviewer that it is easy to see that Earth systems vary through time (i.e., or transient in the words of the reviewer) and we agree that these variations in the environment are relevant for defining flows and loadings, which is why there is an entire separate report designed to characterize the surface water flow systems. However, in comparison to flows in creeks which can change from almost no flow to flood conditions in the spring, groundwater flow and loadings through the tight bedrock into which the AEX ramp will be constructed will be relatively unaffected by daily or seasonal variations at surface and thus are relatively intransient in the context of the examples that the reviewer has provided.

#	Comments	Great Bear Resources Response
	"transient" through time, which can be important for defining flows and loadings of mercury, sulphate, and other elements. Kinross does not model groundwater at the Great Bear Project using naturally transient conditions. Instead, Kinross only models groundwater at Great Bear with "steady state" conditions, where groundwater flows and loadings are constant all the time, every day, every season, every year, every decade, etc. For Advanced Exploration, at what point in the future was groundwater modelled? No one can say, but the obvious assumption is that it represents conditions a long time into the future. No one can say because Kinross continues to refuse transient modelling. Groundwater modellers for Great Bear have stated that transient modelling is not needed despite having no transient data, no transient measurements, and no transient modelling1. I suspect that Kinross is strongly opposing transient groundwater modelling because it requires additional site measurements and parameters apparently not measured at the Great Bear Project. Transient groundwater modelling at the Great Bear Project is seriously needed to understand better the impacts and effects on (1) groundwater inflows around the mine and (2) groundwater movement throughout all hydrogeologic layers and surrounding environment, as time passes. Kinross has pointed out that the effects of drought and climate change cannot be estimated, which is because only steady-state modelling was conducted.	The reviewer's inaccurate statement that no transient data, in the sense the reviewer uses the term transient, has been acquired at site is false, and the reviewer incorrectly insinuates that Great Bear Resources has not elected to acquire any temporal data. Such data, including groundwater and surface water level measurements, surface flows, weather data, etc., has been reported to date and continues to be collected. With respect to the AEX Program (an underground ramp only without open pits), Great Bear Resources has previously shared with the commentator that assessing changes in groundwater inflow to the ramp is not relevant where such changes are overwhelmed by the much greater changes due to the project over the long term. The philosophy taken is that by assessing the maximum extent of the mine, rather than the smaller inflows at immediate steps along the way, Great Bear Resources is being conservative with respect to impacts to surface water features. In terms of an adequacy of data to complete transient modelling, WSP has worked on almost every mine site in northern Ontario and has access to parameters from other analog sites. The reviewer is likely aware that there is a much smaller range of storage related parameter values that have a large impact transient inflows and still be realistic, compared to non-storage related parameters (i.e., hydraulic conductivity). This is particularly true for simulating a ramp that develops gradually. Given that groundwater inflows to underground workings in northern Ontario simply don't change much from day to day and the slow rate of ramp progression, the use of parameters from analog sites would be sufficient for assessing transient inflows and consistent with expectations of the environmental assessment process. The final part of this comment, the reviewer states that Great Bear Resources has not released the additional information from its steady state model. Great Bear Resources is engaging in good faith with stakeholders and has responded to comments. To date, the requests for transient modelling from the reviewer have concerned the groundwater model developed for the assessment of stream impacts, however, Great Bear Resources is not ruling out the use transient modelling in the future.

#	Comments	Great Bear Resources Response
	Because steady-state modelling of some distant future but unknown time was modelled for Advanced Exploration, this is obviously the modelling that would also apply to proposed mining in the Mercury Study Plan. However, the steady-state modelling for Advanced Exploration was likely wrong but Kinross has not released the additional information from its steady-state model to confirm this.	
N3	During proposed exploration and later mining, groundwater will be drawn from all depths into the underground mine at least 500 meters (0.5 km) deep vertically. However, Kinross will release only the drawdown map for the uppermost 36 m of overburden, and not the remaining ~500 m vertical thickness of rock. This incorrectly implies (1) drawdown happens instantaneously for long lateral distances throughout the Great Bear site and (2) transient conditions are minor because they will only be up to 36m vertically. In situations where groundwater levels will fluctuate more than 500 meters vertically, non-steady "transient" modelling is certainly needed. In fact, groundwater levels, forced by Kinross pumping, varying by roughly 500 m vertically (varying by roughly 0.5 kilometers below the land surface) at the Great Bear Project is one of the best examples of where transient groundwater modelling is critical for reliable and realistic flow directions and associated loadings of mercury, sulphate, and other elements. The proposed open pits at Great Bear will also lead to significant transient groundwater flows and geochemical loadings like mercury and sulphate closer to the land surface but are ignored by Kinross.	In response to similar comments to this comment, drawdown cones at different depths in the bedrock system have been provided with the updated PTTW application. The reviewer states that by originally including only these figures Great Bear Resources implies 1) drawdown happens instantaneously over long distances and 2) transient conditions are minor. The reviewer is reminded that the report repeatedly indicates that the ramp will take five years to construct, which is hardly instantaneous. Furthermore, as previously communicated with the reviewer, the ramp will only advance a few meters per day, meaning groundwater inflows and associated loadings to the ramp will not grossly vary from day to day, simply because the ramp does not change much from day to day. It is likely also worth noting that the conclusion that such figures imply instantaneous appearance of maximum drawdown is an atypical comment from a hydrogeological reviewer. The reviewer then repeats that transient modelling is needed to properly simulate mercury and other loadings, similar to previous comments, but this time introduces the open pits. Seasonal pumping rates from the open pits can be expected to be many, many times greater than to the ramp or underground, in large part due to direct precipitation and snowmelt on exposed surfaces, which are highly seasonal. These are likely to be substantially greater than the seasonal variations in loadings from the groundwater system, particularly after the groundwater previously held in storage near the open pits will have been depleted by dewatering from the previously constructed underground. For these reasons, transient groundwater modelling may also be of little value to the predictions of loadings from the open pits.

#	Comments	Great Bear Resources Response
N4	Additionally, Kinross misleads by indicating shallow contaminated groundwater will not escape to the environment but would be drawn into the pumped-down underground mine1. This is false at early times and only becomes reasonable after unknown longer times as steady-state conditions are approached. The lack of transient modelling prevents anyone from proving how long it will take to reach steady-state conditions and prevent contaminated groundwater from escaping. Based on this error alone of steady-state groundwater modelling, Section 3.4.2 of the Mercury Study Plan is remarkable in that it simply states, "These numerical groundwater flow models [of FEFLOW 7.2] consider three dimensional steady-state flow conditions and implement an equivalent porous media approach which is deemed sufficient for characterizing the overall groundwater flow regime at the scale of this analysis." This is wrong, because FEFLOW 7.2 can also simulate transient conditions. Kinross is misleading readers here by not revealing the full capability of this groundwater model including transient modelling needed for the Mercury Study and for general impacts of the Project. In any case, it is clear that steady-state, always-the-same-and-not-varying groundwater modelling, for conditions at some distant but unknown time, will be used to unreliably simulate the critical groundwater pathways and loadings for mercury and sulphate at the Great Bear Project.	The capture of shallow groundwater by the AEX Program is not one of the proposed methods to mitigate the risk of groundwater contamination proposed to the MECP in the ECA application for the early stages of development, and it is false to suggest that Great Bear Resources is being misleading to the reader to think that Great Bear Resources is reliant on this as part of the groundwater cone as a containment control strategy. Great Bear Resources has repeatedly indicated that contact water during the AEX Program will be contained within lined facilities and seepage collection systems have been proposed as a backup. If Great Bear Resources was attempting to "mislead" stakeholders into thinking that the drawdown cone of the ramp could be counted on for containment, why would they build a lined facility? It is not clear how the reviewer is contributing to a genuine dialogue through such statements or how the use of lined facilities at the early stages of ramp development is indication of an error of the steady state model. At no time did Great Bear Resources state the FELOW 7.2 could not be used for transient modelling, and again the reviewer is wrong to state Great Bear Resources is "misleading" readers by disingenuously attributing such inferences to them. Furthermore, information on FEFLOW capabilities are widely available online and would be certainly known to the experts employed by various stakeholders, and it would be rash to think if such a brazen lie was attempted that it would not be quoted by one of the reviewers. The remainder of the comment about the criticality of the groundwater pathways is essentially a repeat of the previous comment and is addressed above.

#	Comments	Great Bear Resources Response
N5	Furthermore, the second part of the quotation above on "equivalent porous media" deceptively hides another important flaw. Groundwater moving through irregular and scattered cracks (fractures) in Great Bear rock will be instead incorrectly modelled as smoothed layers like sand and gravel. Kinross has cryptically "deemed sufficient" this unrealistic modelling based on no data and no evidence that groundwater flow through fractured rock at Great Bear is like groundwater flow through sand, gravel, silt, etc. Without proof otherwise, the porous-media modelling planned for the Mercury Study is not "sufficient" and is plain wrong and misleading. Therefore, Grassy Narrows First Nation should understand that this Mercury Study Plan contains a program for Groundwater Modelling that matches that for Advanced Exploration. The current groundwater modelling is unreliable and likely wrong in light of many incorrect and unjustified assumptions made by Kinross. The Mercury Study Plan shows these errors will be continued, including the false assumption that groundwater flow will be steady state during mining, being the same every day, every season, every year, every decade, etc. As a result, I expect that Kinross will underestimate the important groundwater flow leaving its Great Bear site. Along with problems with the proposed Geochemical Characterization discussed above, this will underestimate the loadings of mercury, sulphate, and other elements leaving the Great Bear site. This will preclude a reliable outcome from the proposed Mercury Study. If Kinross corrects the proposed groundwater modelling in the Mercury Study Plan, then Advanced	The reviewer here is critical of the equivalent porous media (EPM) approach, suggesting an EPM model is "unrealistic", but yet does not preface their opinion with the fact that this approach is widely used to assess groundwater related impacts at almost all mining projects across the province (in some cases, only simplified analytical equations are used) and widely used in academia and accepted by Federal regulators for the simulation of mine workings. This suggests a lack familiarity of the reviewer with groundwater modelling best practices and industry standards, particularly in the context of mine development assessments such as this one. The presence of bedrock fractures and their effect on groundwater flows is well understood and accounted for by Great Bear Resources in its approach. The entire point of EPM is that it equates groundwater flow rates to the discrete media, which is what is relevant in the determination of loading rates and surface water interactions. This comment also seems to contradict the reviewer's own promotion of FEFLOW transient modelling capabilities previously, which up to this point appear to have been the reviewer's main concern. Given that EPM models have been deemed sufficient for the evaluation of groundwater impacts in recent assessments, it is not "misleading" on the part of Great Bear Resources to expect to use a commonly accepted approach. The lack of objections to the EPM approach from all other groundwater reviewers of the project also suggests that the reviewer appears to be isolated in their opinion. The commentator goes on to make several incorrect statements in the last paragraph. He states that Great Bear Resources has falsely assumed that groundwater flow will be "steady state during mining", when Great Bear Resources repeatedly gives a multi-year time frame for mine development. Great Bear Resources does contend that the steady state model will overestimate the size of the drawdown cone in the short term and therefore will be conservative with respect to both stream impacts and groundwater drawdowns, which is different from assuming the instantaneous creation of steady state conditions attributed by the reviewer to Great Bear Resources. The reviewer also "expect(s) that Kinross will underestimate the important groundwater flow leaving its Great Bear site", which will "underestimate the loadings", but does not provide any evidence or detail to support this statement or indicate if the underestimation they expect will be material. This suggests that the reviewer does not have a detailed understanding of the physical process that are key to the interactions of the proposed AEX development with the local groundwater flow system. Otherwise,

#	Comments	Great Bear Resources Response
	Exploration should be stopped because it is already based on the misleading and wrong modelling.	the reviewer would have clearly laid out cause and effect, rather than relying on vague, high-level arguments. Given that groundwater represents only a minor quantity of the total water balance at an operating mine, that loadings to the environment will also impacted by treatment and desulfurization in the mine processes, this statement seems premature, and is not in line with other mining operations in the province.
O. Water Quality Modelling		
O1	Section 3.4.3 on water-quality modelling explains that the model called GoldSim will be used for water-flow and water-quality modelling at the Great Bear Project. Here are some statements from Section 3.4.3 about the GoldSim model. – GoldSim will "stimulate [sic] the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project". – "The GoldSim model domain includes waterbodies potentially impacted by the Project within the PA, LSA and RSA." It is not clear from these statements that GoldSim is not like models such as groundwater (see above) that simulate the movement and chemistry of waters (1) across a site-wide grid of mathematical elements or (2) along a grid of mathematical elements along lake or a creek like Dixie Creek where groundwater can alternately enter and exit the surface waterbodies over short distances. Instead, GoldSim uses user-defined "compartments" or "conceptual boxes" such as one for the western portion of Dixie	Please see response to comments F1, F2 and F3.

#	Comments	Great Bear Resources Response
	Creek near the Great Bear site and another for the eastern portion near the site. The human modellers then conceptually connect these two boxes and any other selected boxes in the GoldSim model to create "nodes". Then the modellers choose the inputs, outputs, and internal conditions and processes that they think apply to each box and node. This should include variable and transient conditions that exist at the Great Bear site over days, seasons, years, and decades, but we already know from the proposed groundwater modelling that transient conditions for at least one important pathway for mercury and sulphate will be ignored and thus will not reliable (see above). Now it is clearer what Kinross means by saying, "Sulphate, mercury and methylmercury predictions will be generated for waterbodies represented by model nodes shown in Figure 3-2." Thus, predictions for mercury and sulphate will be generated only at "nodes" that do not literally simulate waterbodies in their environmental complexity, but simply represent the "boxes" and "nodes" and internal conditions that Kinross chooses to assume, estimate, and simulate.	
O2	Figure 3-2 in the Mercury Study Plan shows that the Chukuni River will be modelled only at two nodes: CHK-1 immediately above the property boundary and CHK-2 immediately below the boundary. Therefore, everything above the property boundary in the Chukuni River will be simulated as a single "node" or "box" for which the modellers will define all the upstream physical, geochemical, and water-quality properties, likely with many simplifications and/or assumptions. Then the	Please see responses to comments F1, F2 and F3.

#	Comments	Great Bear Resources Response
	physical and chemical contributions from Dixie Creek Node DIX-5 will be "mixed" with Node CHK-1 to obtain predicted flows and concentrations at Node CHK-2, subject to currently unstated simplifications and/or assumptions possibly like adsorption on river-bed sediments or biological processes to remove additional mercury and sulphate from the water at CHK-2. Because of this "node" approach, important details like an initial dilution zone (a mixing zone) in the Chukuni River between Nodes CHK-1 and CHK-2 cannot be simulated in sufficient detail. This gives you some idea how the GoldSim model will "simulate" water flow and water quality at, beneath, and around the Great Bear site.	
O3	The GoldSim model for the Great Bear Project can be easily manipulated by the modellers but this is hidden from external inspection by Grassy Narrows First Nation. For example, the modellers can apply a condition where aqueous concentrations of mercury, sulphate, and other elements are allowed to decrease but are not allowed to increase as water "flows" through the boxes and nodes. Section 3.4.3 promises to "[p]rovide a clear description and rationale for model input parameters and assumptions".This is appropriate and important but in my experience I have never seen this provided in sufficient detail for any GoldSim model. Therefore, to understand how the GoldSim water-quality model for the Great Bear Project has been designed and manipulated through all of its boxes and nodes, and thus whether its results and predictions are reasonable, a relatively large amount of information on the GoldSim model will be needed from	Data inputs, assumptions, and calculations will be explicitly documented in the model reporting for the GoldSim model. We agree with the reviewer, that the intended level of detail will exceed typical reporting standards for effects assessments, providing greater transparency.

#	Comments	Great Bear Resources Response
	Kinross. I have not seen this provided in detail before, but it will be required for the Great Bear Mercury Study.	

Advanced Exploration Project

Great Bear Resources Ltd.'s Response to Source Environmental Associates Inc. Technical Memorandum – Review of Great Bear Resources Mercury Study Plan, dated April 29, 2025

#	Comments & Rationale	Response
A.	**Alignment with Tailored Impact Statement Guidelines (TISG)**	
A.1	**Lack of Maps for Proposed Study Areas** Section 7.3.1 of the Great Bear Project TISG states the impact statement for each valued component (VC) identified must describe the spatial boundaries of said VC and a rationale for the boundaries. These spatial boundaries must be shown on maps in each impact statement. The Mercury Study Plan does not include maps for the PA (Project Area), LSA (Local Study Area) and RSA (Regional Study Area) identified for the VC methylmercury, which makes it hard for reviewers to understand where the boundaries lie and the reasoning behind them. These maps should be included in the Mercury Study Plan.	The Mercury Study Plan, although requested by the TISG, is not part of the Impact Statement and spatial boundaries related to the Impact Statement are not relevant to the Plan. Mapping will be provided in future documentation as appropriate.
A.2	**Regional Study Area for Cumulative Effects** An identified VC in the TISG is the health of Indigenous Peoples in relation to potential changes in the surrounding watershed. This includes downstream water quality from effluent discharge and past industrial activity. More explanation is required in the Study Plan to explain how cumulative effects are addressed. For example, the Regional Study Area (RSA) described in the Mercury Study Plan may be too narrow for a cumulative effects assessment, as it does not include areas of significant historic mercury contamination such as the English-Wabigoon River system which are downstream of the proposed industrial effluent discharge point. To ensure a comprehensive assessment of cumulative effects for this identified VC, the RSA should be expanded to include areas of historic mercury contamination that have impacted ANA.	Cumulative effects will be included in the Impact Statement consistent with the TISG and the Federal guidance, including the current guidance (*Operational Policy Statement: Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012*). Three spatial study areas have been defined for the Impact Statement as required. The Regional Study Area (RSA) for the Impact Statement encompasses the Project Area (PA) and Local Study Area (LSA). It is the maximum geographical extent or zone of influence assessed.

#	Comments & Rationale	Response
B.	**Baseline Methodology**	
B.1	**Inclusion of the Exploration Phase in the Study Plan** The Study Plan should include the proposed underground exploration phase as well as the Life of Mine project described in the Project Description (January 2024). Please indicate if the exploration project phase is included in the study plan. This phase has the potential to generate methylmercury, as noted in previous submissions, and should be included in the study. This should include both early exploration activities, and the "Advance Exploration" program, which includes construction of key components of the mine.	The Mercury Study Plan was a requirement of the TISGs, which are for the designated Great Bear Project only (i.e., proposed open pit and underground mine), and do not apply to exploration and advanced exploration.
B.2	**Documentation of Missed Sampling Events** Establishing a sufficient baseline dataset is critical for conducting an effects assessment. In section 2.2 Summary of Analytical Methodology, water quality will be sampled monthly providing flow is present and the site can be safely accessed. To ensure a complete dataset, the proponent should ensure any missed sampling events are recorded with a rationale and attempts to re-sample the location(s) should be made within the monthly sampling period. In order to establish a reliable baseline dataset, sampling should be carried out over three years, and should include monthly sampling, as well as 5 samples in 30 days during periods of low and high flows. Also, in order to establish a valid baseline, the proponent should ensure that appropriate baseline monitoring sites are established which: a. Do not reflect regional sources of contamination (e.g. upstream mines), b. Do not reflect contamination from earlier stages of this project,	The baseline sampling program has been developed in alignment with the applicable regulatory framework for proposed mining projects in Ontario. It includes long-term monthly sampling designed to capture natural variability and to characterize pre-development conditions, consistent with Ontario's regulatory environment and regulator expectations. The baseline sampling program incorporates reference stations that are not anticipated to be affected by Project development, and monitoring will continue throughout the life of the Project in accordance with applicable approvals.

#	Comments & Rationale	Response
	c. Reference stations that will not be impacted by later stages of this project, d. Will continue to be monitored throughout the project. The proponent should also ensure that the correct sampling and lab methodology are used to ensure that all contaminant levels above baseline are detected reliably.	
B.3	**Inclusion of Mercury, Methylmercury and Sulphate Loadings** Loadings may be a useful measurement of mercury, methylmercury and sulphate and provide an indication of the total mass of these parameters anticipated in the project waterbodies. The study plan should include a requirement to develop monthly predictions of loadings for mercury, methylmercury and sulphate (and other substances affecting methylation) that may enter the project area waterbodies, including the Chukuni River.	Final reporting will include loading estimates for sulphate, mercury and methylmercury, and other relevant parameters, as appropriate, for Project-area watercourse and waterbodies, including the Chukuni River where applicable.
B.4	**Baseline Sampling Locations** Methylmercury concentrations observed in monitoring data in the project area ranged from 1.98% to 14.35% (of total mercury) reflecting that there are certain project areas that generate more methylmercury than others. The Study Plan should provide a rationale of how both surface water and groundwater sampling locations in the Study Plan have been chosen in relation to expected direct and indirect effects and discuss the potential influence of project waters on wetted areas. Given that methylmercury is primarily generated under anoxic conditions, which can vary across the project site, the Study Plan should provide a rationale as to how the baseline sampling locations are sufficient to capture the range in methylmercury. Currently, the Mercury Study Plan does not include a sufficient level of detail for each proposed monitoring site to assess whether the purpose or rationale of the location fulfills the intent of the baseline program. The program should ensure that each downstream sampling point is sufficient to establish a robust baseline against which any changes in downstream water quality related to mercury and	Consistent with standard practice, baseline sampling locations have been selected to characterize pre-development conditions across areas that may be directly or indirectly affected by Project development. Site selection includes representative upstream, downstream and reference locations, as well as areas of potential interaction between project infrastructure and surface water or groundwater-surface water interactions. Locations have been chosen to capture spatial variability, account for natural influences (e.g., geology, anoxic environments, riverine systems), and provide sufficient coverage to support the effects assessment. The baseline program has been designed to establish a robust dataset that will enable assessment of any Project-related changes in downstream water quality related to mercury and methylation, as part of the final reporting under the Mercury Study Plan.

#	Comments & Rationale	Response
	methylation can be measured.	
B.5	**Unnamed Waterbodies #1 and #2** According to Section 2.2.1 Water Quality, seasonal baseline surface water quality sampling for temperature, pH and dissolved oxygen occurs in Pakwash Lake, Genesee Lake and Unnamed Waterbody #6. The Study Plan should include a rationale as to why there is no planned physicochemical property sampling proposed for Unnamed Waterbodies #1 and #2. Additionally, the Study Plan should list which waterbodies are included in the multi-season fish habitat assessments.	Physicochemical data (temperature, pH and oxygen) are monitored in Unnamed Waterbodies 1 and 2. Unnamed Waterbodies 1 and 2 are predicted to be impacted by the mine site development (displaced or considerably altered) and will be compensated for in their entirety within the final Fish Habitat Offset and Compensation Plan.
B.6	**Additional Data Request- Water Quality** Baseline water quality reporting should include the 95th percentile, minimum and maximum values for all waterbodies sampled, as well as an assessment of seasonal variation. Figures should be provided showing seasonal variation for the range in mercury, methylmercury and sulphate baseline data. Baseline data should cover 3 years and include monthly sampling, as well as 5 samples in 30 days during periods of low and high flows.	Baseline water quality reporting for mercury and methylmercury reporting will include 95th percentile, minimum and maximum values for all waterbodies sampled, as well as figures showing seasonal variation. The baseline sampling program has been developed in alignment with the applicable regulatory framework for proposed mining projects in Ontario and includes long-term monthly sampling designed to capture natural variability in pre-development conditions.
B.7	**Mercury and Methylmercury in Temporary Closure** Spatial and temporal boundaries for the effects assessment are discussed by phase of mine life. However, there is no discussion of a Care and Maintenance phase, which commonly occurs in mining, according to economic conditions. Mines often plan for operations and closure phases but lack rigorous assessment of temporary closures and their implications for the receiving environment. The effects assessment cannot be considered complete without an assessment of a temporary closure scenario. The proponent should consider a 'worst case scenario' during operations, where the mine is forced to temporarily shut down.	The Mercury Study Plan was a requirement of the TISGs which are for the designated Project (the proposed open pit and underground mine). The phases described in the Plan are consistent with the TISG and the Impact Statement in preparation. Closure of mines in Ontario is governed by the *Mining Act*. The Closure Plan required by the *Mining Act* will address temporary suspension, state of inactivity and final closure, including chemical monitoring.

#	Comments & Rationale	Response
	Implications for water management, water treatment and potential for adverse effects related to mercury, methylmercury and sulphate in a care and maintenance scenario should be assessed in the Study Plan.	
B.8	**Traditional Food Harvesting Considerations** While the sampling locations proposed as part of the Mercury Study Plan attempt to assess the impact of effluent release on water quality as it flows through the waterbodies surrounding the mine site, there is no discussion in the Mercury Study Plan regarding how it will assess potential impacts on human health or how the movement of fish and other species that are consumed will be considered. For example, Great Bear should assess, as part of the Mercury Study Plan, how far key fish species for Indigenous consumption, including walleye, migrate to and from the project site, its receiving waters, and downstream water bodies that are potentially impacted. How does the study plan presented account for movement of species that will ultimately be consumed potentially outside of the study area? The study plan also does not apply consumption guidelines that are designed for Indigenous subsistence consumers of fish, nor does it consider the pre-existing mercury exposure that Grassy Narrows people have experienced. The study plan does not appear to take into account the unique mercury risks associated with Grassy Narrows people who consume fish as part of their way of life and who have previously experienced high levels of mercury exposure.	Studies have shown that Walleye tend to show a high fidelity to their habitats. A study to track within-year and between-year movement of Walleyes in a chain of 10 interconnected lakes in Vilas County, Wisconsin showed that most (76%) of Walleye remained in the same lake within and between years (Weeks and Hansen 2009). Similar to the Great Brear Project RSA, a study of Walleye movement on the highly fragmented (due to dams) Ottawa River determined that Walleye movement was primarily upstream with limited downstream movement. As could be expected movement among impounded reaches was not detected other than a few instances where fish were entrained through the dams (Haxton et al. 2015). Based on the studies, it is likely that the Walleye population at the site is largely confined by the known barriers including the Snowshoe Rapids on the Chukuni River, and the Manitou Generating Station and Ear Falls Generating Station on the English River. The mercury study will assess potential increased risks to Indigenous consumers of fish harvested from the PA and downstream waterbodies due to existing conditions and the potential influence of the Project by: - Characterizing baseline concentrations of mercury and methyl mercury in fish (Walleye, Northern Pike and Whitefish) sampled during baseline studies around the Project (baseline fish quality) in comparison to baseline concentrations of mercury and methyl mercury in surface water from the same water bodies (baseline surface water quality). Site-specific bioaccumulation factors (BAFs) from surface water to fish will be calculated for mercury and methyl mercury from the baseline data. - Predicting the potential changes in mercury and methylmercury concentrations in surface water from the Project within the receiving environment (Chukuni River) and downstream waterbodies including the English River. - Predicting the potential changes in mercury and methylmercury concentrations in fish in the same water bodies based on the predicted changes in mercury and methyl mercury concentrations in surface water and the calculated BAFs from surface water to fish. - Predicting the potential increased risks to fish consumers from consumption of fish harvested from the PA and downstream waterbodies, calculated using fish consumption rates for average and subsistence consumers of fish reported in the *First Nations Food, Nutrition and Environment Study for Ontario, 2014* (Chan et al 2014). Consumption rates reported in this study are based on data provided by Indigenous communities in the Ecozone 1 (Boreal Shield Subarctic) region, including Grassy Narrows. - The movement of fish in the PA is largely restricted by infrastructure barriers (i.e., dams) and can be

#	Comments & Rationale	Response
		extensive for older or larger predatory fish (e.g., Walleye and Northern Pike) migrating from one waterbody to the next searching for food and mates. The mercury study will be used to inform health risks related to mercury exposure via fish consumption and can be used to estimate consumption guidelines, but this task is not the focus of the study as consumption guidelines are recommended by the Province and Health Canada guidance. Consumption guidelines depend on several assumptions that influence risks, such as the person and life stage, species and size of fish, mercury concentration, consumption rate and the toxicity reference value. The mercury study will primarily calculate risks based on measured baseline concentrations of mercury and projected changes in fish concentrations associated with the Project in comparison to the consumption rates reported in the Chan et al (2014) study for the region. The mercury study will not recommend fish consumption guidelines but the risk estimates provided can be used for information purposes related to fish advisories.
B.9	**Lack of Data Provided on Geochemical Characterization to Date** Section 8.3.1. of the TISG provided for the Great Bear Project states that the associated Impact Statement should describe the representativeness of samples collected for acid rock drainage and metal leaching. Despite the Mercury Study Plan stating that baseline geochemical data has been collected since 2022, the plan does not indicate the location of samples or the results of testing thus far. The existing data for baseline geochemical analysis that will be included in the water quality model (GoldSim) for methylmercury should be provided. Significant deficiencies in the ML-ARD data and study plan have been identified by Source and by other reviewers in previous submissions. These deficiencies should be corrected, and the associated studies completed and reviewed, before the geochemical data is used as an input in the effects assessment.	Geochemical baseline information will be provided in the Impact Statement, as outlined in the TISG. This will include the location of samples as specified in the TISG, along with the results of ML/ARD testing. Water quality estimates for site discharge or fugitive seepage to receivers are being prepared and represent some of the inputs for additional receiving environment modelling (i.e., for methylmercury). Reporting summarizing the mine site water quality modelling and supporting geochemical data will be provided as part of the Impact Statement. ANA has previously made numerous false claims that geochemical and other studies being conducted for the Project are not credible. Great Bear Resources has previously addressed these comments. As previously indicated, baseline geochemical characterization programs have been conducted and are continuing for the Project, following industry standard methods, under the direction of experienced professional geoscientists. This includes the assessment of ML/ARD potential for mine rock, ore, tailings, and overburden, per the approaches and methods in MEND (2009). The results of these studies will be used to assess potential environmental effects of the Project and ensure that they are appropriately mitigated and managed.
B.10	**Quality Assurance for Geochemical Samples** The methodology for geochemical characterization described in Section 3.4.1 of the Mercury Study Plan does not include quality assurance / quality control procedures, including but not limited to laboratory certificates of analysis as requested in Section 8.3.1 of the TISG. What are the procedures to follow for quality assurance / quality control for samples taken for geochemical characterization?	Geochemical baseline information will be provided in the Impact Statement, as outlined in the TISG. As specified in the TISG, laboratory certificates of analysis will be provided for all samples, along with information related to analytical methodology and other quality assurance / control measures.

#	Comments & Rationale	Response
B.11	**Inclusion of Worst Case Scenario in Water Quality Modelling** Section 8.3.2 of the TISG states the Impact Statement for the Biophysical Environment must provide base case (i.e. most likely, mean, median) and worst case (e.g. 75th-90th percentile) scenarios, plus any applicable sensitivity scenarios. However, the Mercury Study Plan indicates the GoldSim model used for Mercury and Methylmercury Water Quality Modelling (Section 3.4.3) will only identify and describe the base case (expected case) plus sensitivity scenarios. This is not considered appropriate as the worst case scenario should also be included in future modelling for mercury and methylmercury concentrations. Considering the legacy of mercury contamination in the surrounding region, it is critical that the 'worst case' is considered and modelled, not just the expected scenario.	The proposed water quality modelling approach, including the forecasting of mercury and methylmercury concentrations, follows standard industry practice by incorporating a range of sensitivity cases to account for variability and uncertainty in key inputs. An upper-case scenario will be identified based on the modelling results. This approach, applying the identification and discussion of an upper-case scenario, will be used consistently across model components, including methylmercury production, so that both expected and upper-bound outcomes are explicitly considered in the assessment.

Re: Estimation of [MeHg] from SO_4 loading – interim update

---

1. Introduction

Sulphate-reducing bacteria (SRB) are known to participate in the mercury-methylation process in freshwater environments (Gilmour et al. 1992). The production of methyl-mercury (MeHg) can be limited by sulphate (SO_4) availability (Orem et al. 2020) and therefore added SO_4 can stimulate MeHg production under certain conditions (e.g., in anoxic environments where sufficient concentrations of organic carbon and inorganic mercury are present; e.g., Watras et al. 1995). There is therefore concern with SO_4 loading into freshwater ecosystems, especially where consumption of fish is significant, because MeHg bioaccumulates in fish tissue posing a risk to human health (Driscoll et al. 2013).

In this memorandum we present our approach for estimating the potential effect of SO_4 loading from the Great Bear project effluent to the Chukuni River on downstream MeHg concentrations. The quantification of SO_4 loading will be based on conventional mass-balance modelling. There is no standard approach for estimating changes in MeHg concentrations due to changes in SO_4 loading in freshwater environments – the conditions in each aquatic system vary and available information to define the SO_4 – MeHg relationship also vary. We derived an empirical SO_4-MeHg loading relationship using the available information from the freshwater environment downstream of the Chukini River, supplemented with information from several research studies completed in similar environments. Sensitivity analysis will be performed to assess the quantitative implications of the inherent uncertainty in model parameters. The approach will be updated with site-specific information collected from the modelled area, in late September, 2025.

The results of this modelling will provide input data for bioaccumulation and health-risk modelling to be completed by WSP Global Inc.

2. Overview of Approach

A mass-balance model will be used to estimate SO_4 loading (effluent and background) for the 23 waterbodies/watercourses between the Great Bear project effluent discharge location on the Chukuni River and Grassy Narrows Lake. MeHg concentrations will be estimated based on published relationships between changes in SO_4 loading and changes in pore-water MeHg concentrations. The current approach incorporates SO_4 influx rates to sediment and MeHg efflux rates to surface water, based on data from aquatic system downstream of the Chukuni River.

The fundamental assumption upon which this modelling exercise is predicated is that SO_4 availability limits MeHg production in the Chukuni–English River system, as opposed to limitation by organic carbon supply, inorganic mercury supply, or other potentially limiting factors. All other factors are conservatively assumed to be non-limiting, such that MeHg stimulation by SO_4 is unconstrained. A sensitivity analysis will be completed to assess the importance of changes in effluent loading and model coefficients/sub-models and inherent assumptions therein. The sub-models numerically predict the effects of the following primary factors that stimulate MeHg production and uptake in the aquatic environment (Table 1):

Table 1. Overview of model structure.

Sub-model	Relevance
Hydrology	Estimated flows (discharge rates) of each waterbody are used to calculate SO_4 and MeHg loading/fluxes and concentrations.
SO_4 Loading	The SO_4-MeHg sub-model (below) is based on the projected increase in SO_4 loading (due to project activities) relative to the pre-project (background) loading.
SO_4 Influx to Sediment	The flux of SO_4 to sediments is estimated based on the concentration gradient between the water column and sediment porewater.
SO_4 Loading vs. MeHg Production	The predicted change in pore-water MeHg due to project activities is based on SO_4 loading above the background load. The SO_4-MeHg relationship is based on empirical data from several published studies that are judged to be relevant to the project setting (Branfireun et al. 1999; Branfireun et al. 2001; Jeremiason et al. 2006; Mitchell et al. 2008; Branfireun 2024; hereafter, “the peatland studies”).
MeHg Efflux from Sediment	The flux of MeHg from sediments is estimated based on the concentration gradient between the sediment porewater and water column.
Temperature-dependence of SO_4-reduction	For sensitivity analysis, a lower MeHg yield was modelled based on a lower SO_4-reduction rate predicted to occur at the low temperatures likely associated with (deepwater) Hg-methylation zones in the study area on a full-year basis (vs. non-winter, near-surface data from the peatland studies).

3. Methods

3.1 Hydrology

The model area includes the waterbodies and watercourses (hereafter referred to collectively as waterbodies) downstream of the effluent-discharge location on the Chukuni River (upstream of Pakwash Lake) to the English River upstream of where it joins Little Fox Lake, north of Grassy Narrows Lake (Figure 1). Grassy Narrows Lake will not be included as one of the modelled waterbodies because it flows into (i.e. is upstream of) the terminal section of the English River within the modelled area (MNR 2025a; Figure 2).

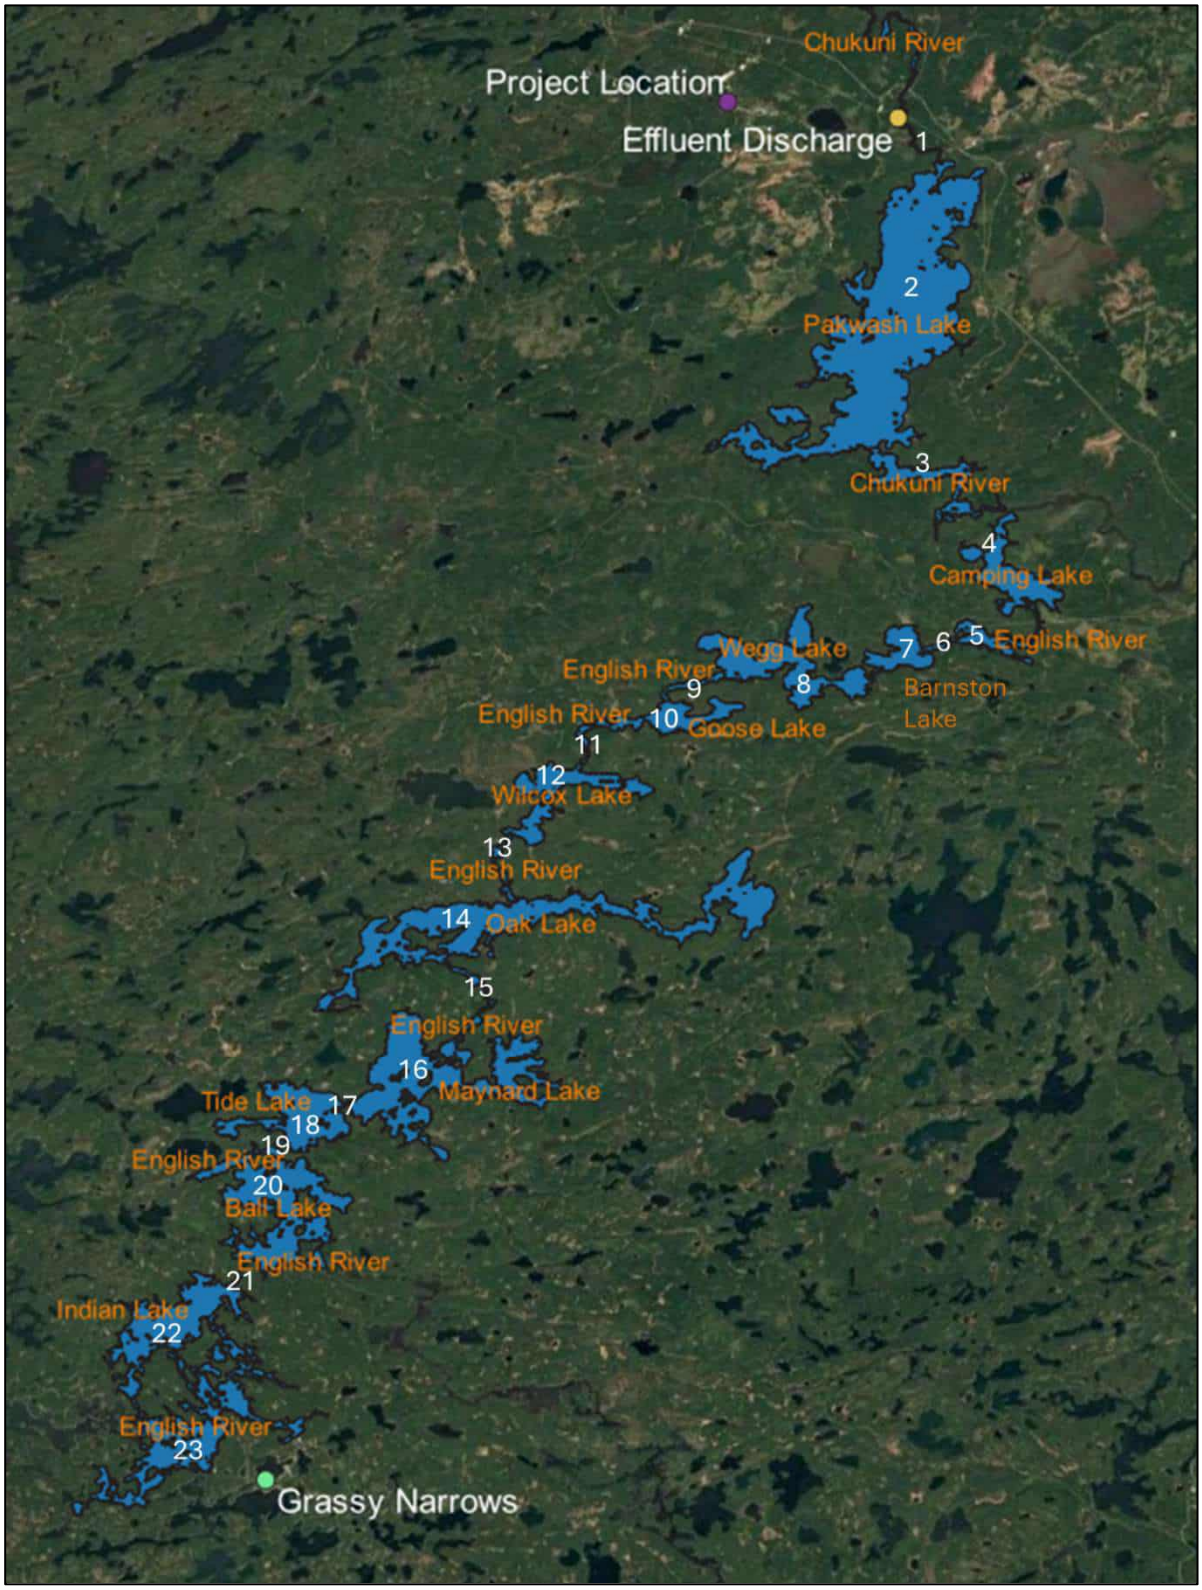

Figure 1. Waterbodies in area to be modelled.

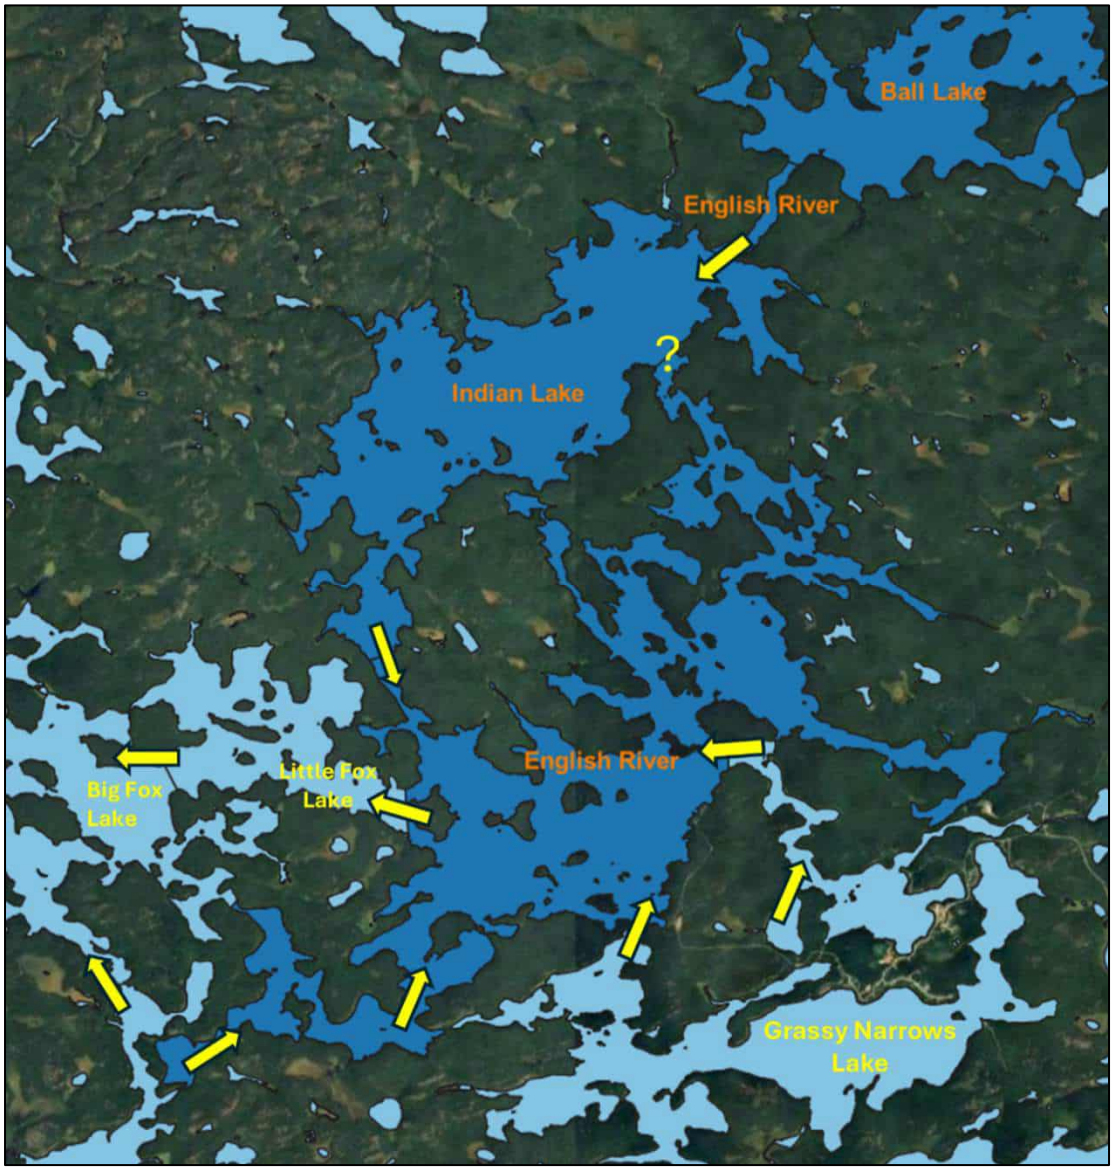

Figure 2. Flow directions in the most downstream area of the model region according to the Ontario Watershed Information Tool (MNR 2025a). The model waterbodies are depicted in dark blue.

The drainage area upstream of the outlet of each waterbody will be calculated using the Ontario Watershed Information Tool (OWIT; MNR 2025a). Annual average ambient flow rates ($Q\text{-}Bkg_{(i)}$) will be estimated for each waterbody based on areal prorating. The annual average flows for the Chukuni River and English River at Manitou Falls will be calculated based on long-term data from WSC (1994–2023) and LWCB (1991–2020), respectively. The flow-area ratio (runoff) at the Chukuni River gauge will be used to estimate flows upstream of the confluence with the English River; the English River at Manitou Falls flow-area ratio will be used to estimate flows downstream of the confluence. While seasonal variation in flow is expected to differ markedly between the two locations because of the dams on the English River, it is expected that the flows of the two watercourses show strong correlation on annual-average basis (i.e., among years). Annual flow rates were chosen for modelling MeHg stimulation by SO_4 in this case, because the purpose of predicting MeHg is to evaluate bioaccumulation change in fish over the course of years.

Table 2. Drainage areas (from OWIT) and flows for regional WSC gauges with the gauges to be used for prorating shown in boldface type.

3.2 Sulphate Loading and Concentrations

3.2.1 Water-column Sulphate Concentrations

The final water-column SO_4 concentration of each waterbody (background + effluent), is calculated as the quotient of the total SO_4 load to that waterbody and the total flow through that water body as

$$[SO_4]_{(i)} = L\text{-}SO_{4(i)} \div Q_{(i)}$$

where

(i) is the waterbody (i.e., 1 of the 23 model compartments)
$[SO_4]_{(i)}$ is the water-column concentration of SO_4 in the i^{th} waterbody (mg/L)
$L\text{-}SO_{4(i)}$ is the total (project + background) loading of SO_4 to the i^{th} waterbody (g/d)
$Q_{(i)}$ is the total flow (discharge) through the i^{th} waterbody (m^3/d)

and

g/m^3 is equivalent to mg/L

3.2.2 Sulphate Loading to Waterbody #1

The total SO_4 load to the Chukuni River upstream of Pakwash Lake, the 1st waterbody in the sequence, is the sum of the background (upstream) SO_4 loading ($L\text{-}SO_4\text{-}Bkg_{(\#1)}$) and effluent loading ($L\text{-}SO_4\text{-}Eff$)

$$L\text{-}SO_{4(\#1)} = L\text{-}SO_4\text{-}Bkg_{(\#1)} + L\text{-}SO_4\text{-}Eff$$

where the background loading is the product of the background concentration ($[SO_4\text{-}Bkg]$) and flow ($Q\text{-}Bkg$)

$$L\text{-}SO_4\text{-}Bkg_{(\#1)} = [SO_4\text{-}Bkg] \times Q\text{-}Bkg$$

and the effluent loading is the product of the effluent concentration ($[SO_4\text{-}Eff]$) and flow ($Q\text{-}Eff$)

$$L\text{-}SO_4\text{-}Eff = [SO_4\text{-}Eff] \times Q\text{-}Eff$$

The background SO_4 concentration ($[SO_4\text{-}Bkg]$) used for modelling is 4.9 mg/L; this concentration is the average of available baseline data collected by WSP (Chukuni River and Pakwash Lake stations; *n* = 168; 2022–2025).

3.2.3 Sulphate Loading to Waterbodies #2–23

For Pakwash Lake and all downstream waterbodies, the SO_4 loading is calculated as the sum of background loading from the immediate watershed only ($L\text{-}SO_4\text{-}WS_{(i)}$) and the in-stream load exported from the upstream waterbody ($L\text{-}SO_4\text{-}out_{(i-1)}$) as

$$L\text{-}SO_{4(i)} = L\text{-}SO_4\text{-}WS_{(i)} + L\text{-}SO_4\text{-}out_{(i-1)}$$

The background watershed loading is the product of the background concentration and immediate-watershed inflow ($Q\text{-}WS_{(i)}$)

$$L\text{-}SO_4\text{-}WS_{(i)} = [SO_4\text{-}Bkg] \times Q\text{-}WS_{(i)}$$

where

$$Q\text{-}WS_{(i)} = Q_{(i)} - Q_{(i-1)}$$

and

$$Q_{(i)} = Q\text{-}Bkg_{(i)} + Q\text{-}Eff$$

The SO_4 exported via the outflow from each waterbody ($L\text{-}SO_4\text{-}out_{(i)}$) is the difference between the total load to that waterbody and the flux of SO_4 lost to the sediments ($F\text{-}SO_{4(i)}$)

$$L\text{-}SO_4\text{-}out_{(i)} = L\text{-}SO_{4(i)} - F\text{-}SO_{4(i)}$$

3.3 Sulphate Flux to Sediments

Fluxes were modelled based on Fick's 1st Law using equations found in Delongchamp et al. (2009). The areal flux ($g/m^2/d$) of SO_4 from the water column to sediment porewater in each waterbody was calculated as

$$F = -1 \times (\Phi \times D_W \div \theta^2) \times (\Delta C \div \Delta x)$$

where

Φ is sediment porosity
D_W is the diffusion coefficient of SO_4 in water
θ is the sediment tortuosity
ΔC is the change in SO_4 concentration between the water column and porewater
Δx is the change in depth within the surficial sediments (assumed to be 10 cm)

Following Delongchamp et al. (2009), tortuosity was estimated from porosity as

$$\theta = 1 - \ln(\Phi^2)$$

The background sediment porewater SO_4 concentration used was 0.2636 mg/L, the average of available data collected by WSP from the Chukuni River and Pakwash Lake (n = 14; Sep 2024; MDL = 0.3 mg/L; ½ MDL substituted for non-detects to calculate average).

The background SO_4 influx to sediment (F-SO_4-Bkg) was calculated based on the background water column SO_4 concentration of 4.9 mg/L. The total SO_4 influx to sediment in each waterbody (F-$SO_{4(i)}$) was calculated based on the total SO_4 concentration of each waterbody ([SO_4]$_{(i)}$); i.e., in the presence of effluent discharge.

3.4 Stimulation of Hg methylation by SRB

The change in sediment efflux of MeHg in each waterbody was estimated based on reports of empirical relationships between changes in SO_4 loading and porewater MeHg concentrations (Table 3). The available studies on this topic were not all included, as some did not express SO_4 loads relative to natural (background) loading (e.g., Harmon et al. 2004) and others reported SO_4 concentrations but not loading (e.g., Gilmour et al. 1992). When only considering the field (mesocosm) studies that did quantify increases in porewater MeHg as a function of augmented SO_4 loading (relative to natural loading), the data available to establish an empirical relationship are from varying temporal scales (days to years), various geographic locations, various depths in sediment, and were collected using variable methods. These studies are, however, to our knowledge the best available sources for establishing an empirical relationship between increased SO_4 loading and Hg methylation. The data considered most representative of the potential effect of SO_4 on MeHg were extracted from the text or figures of each paper. In extracting data from figures, data from multiple sediment depths and replicates were first averaged, and the highest MeHg concentrations in reported timeseries were then extracted, as per a conservative approach. The median ratio (increase in SO_4 load to increase in MeHg concentration) of the available (relevant) data was used to estimate the change in sediment MeHg efflux.

With the exception of Branfireun (2024), the available studies were conducted in peatlands not lakes. We are not aware of any studies conducted in Canadian lakes, or in lakes of the northern United States (or other comparable areas), that have quantified the relationship between change in SO_4 loading and porewater MeHg concentration. The model does <u>not</u> assume that SO_4 or MeHg concentrations or Hg-methylation rates in the study area are comparable to those in peatlands; rather, the model assumes that the stoichiometry — i.e., the proportional change in MeHg in response to increased SO_4 — is comparable to that reported for peatlands, when changes are expressed relative to background levels.

3.5 Sediment MeHg Flux to Water Column

The change in the areal efflux (g/m^2/d) of MeHg from the sediment porewater to the water column in each waterbody (F-MeHg$_{(i)}$) was calculated based on the change in SO_4 influx (Section 3.3) and the empirical SO_4-MeHg relationship discussed above (Section 3.4) as

$$\text{F-MeHg}_{(i)} = \text{F-MeHg-Bkg} \times 0.65 \times \text{F-SO}_{4(i)} \div \text{F-SO}_4\text{-Bkg}$$

The background MeHg efflux rate (F-MeHg-Bkg; i.e., flux out of sediment) was estimated based on available monitoring data and Fick's Law, as described for SO_4 in Section 3.3.

Table 3. Studies of porewater-MeHg increases in response to augmented SO_4 loading.

Reference	Location	Date of experiments	*Duration	SO_4 loading (variable units)		MeHg concentration (ng/L)		SO_4 load (/ Bkg.)	[MeHg] (/ Bkg.)	Ratio	Avg. Ratio

					1.4 mg	187	236	5	1.26	0.25	
					4.2 mg		347	15	1.86	0.12	
										Median:	**0.65**

**Refers to time elapsed prior to the presented data, not necessarily the duration of the entire experiment.*
***Branfireun (2024) used bottle incubations and reported MeHg in supernatant water (deionized and mill effluent) from experimental samples; here it is assumed that the 2-mg/L SO_4 treatment from this study represents background (Bkg.) conditions (allowing relative changes to be quantified for the 10 mg/L and 30 mg/L treatments).*

3.6 Water-column MeHg Concentration

The increase in water-column MeHg concentration (i.e., additional to the background MeHg concentration) of each waterbody ($[MeHg\text{-}Inc]_{(i)}$) was calculated from total sediment efflux (areal efflux in $g/m^2/d$ × lake area in m^2 = g/d) and flow (m^3/d) as

$$[MeHg\text{-}Inc]_{(i)} = F\text{-}MeHg_{(i)} \div Q_{(i)}$$

with concentrations converted from g/m^3 to picograms per litre (pg/L).

Demethylation processes are not considered in the mass balance. This is precautious and reduces model uncertainty concerning demethylation process definition.

3.7 Sensitivity Analysis and Additional Scenarios

Additional effluent discharge scenarios will be evaluated and sensitivity analysis performed to assess the importance of coefficients and assumptions related to temperature, the background MeHg concentration in porewater, and other variables related to flux estimates. For the sensitivity analyses, the model will be run based on the base Operations effluent SO_4 loading scenario.

3.7.1 SO_4 Loading from Project

In addition to the base scenarios for AEX and Operations, two additional scenarios will be modelled: a SO_4 concentration (as annual average) at the approved effluent limit and an increased effluent flow of 25% above the average expected effluent flow for the Operations phase of the project.

3.7.2 Background Porewater MeHg Concentrations

In addition to the median background porewater MeHg value that will be modelled for the base scenario, low and high concentrations will be modelled based on the range of concentrations observed in Pakwash Lake and the Chukuni River in 2024 (WSP data), pending data from the lakes downstream of the Chukuni River (Hutchinson Environmental data) and the concentrations reported by the peatland studies that were used to derive the SO_4-MeHg relationship (i.e., 0.26–1.50 ng/L; Table 3).

3.7.3 Temperature

The effect of temperature on the relationship between SO_4 loading and MeHg generation will be accounted for by assuming a direct relationship between the SO_4-reduction rate and MeHg generation. The effect of temperature on the SO_4-reduction rate will be modelled based on data presented by Robador et al. (2016) for a hypothetical mixture of SO_4-reducing microorganisms with activation energy (Ea) of 70 kJ/mol (data for up to 100% of maximum reduction rate, from their Figure 1b; reproduced below as **Error! Reference source not found.**).

The temperature of porewater was reported by the authors in 2 of the 4 studies used to establish the SO_4-load-[MeHg] relationship (Figure 3). Jeremiason et al. (2006) reported a porewater temperature of 4.5°C associated with their May results. Mitchell et al. (2008) reported average porewater temperatures of 19.8°C

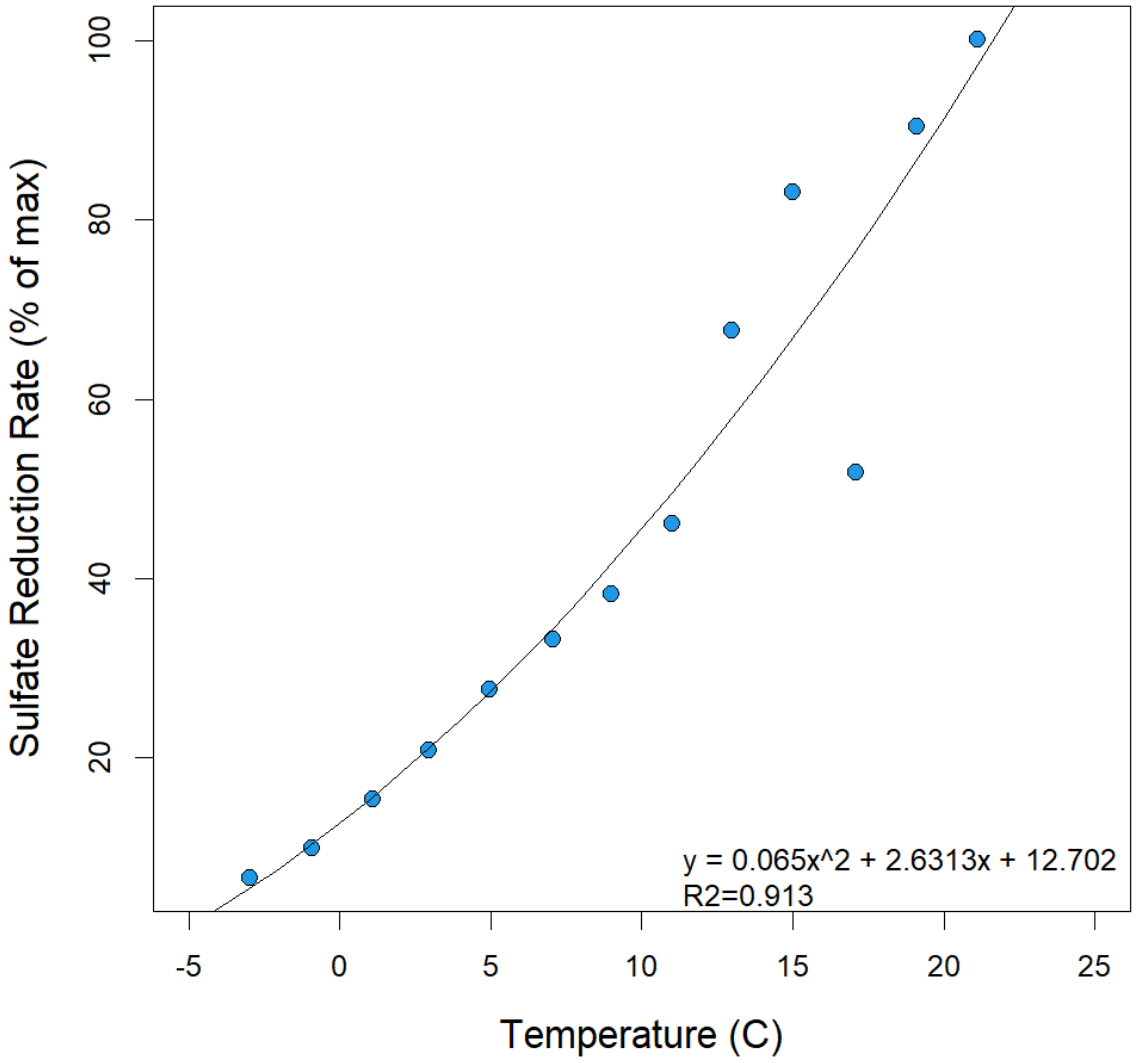

Figure 3. Temperature dependence of sulphate-reduction rate for a hypothetical mixture of SRB (data from Robador et al. 2016).

and 15.2°C at depths of 5 cm and 15 cm, respectively, and an average air temperature of 15°C. The average air temperature was comparable (14°C) during the Sep 1997 experiment of Branfireun et al. (1999), based on historical Environment Canada data for Rawson Lake (Climate ID 6036904). Branfireun et al. (2001) did not report temperatures or the dates of their experiments but noted that treatments were applied "during the snow-free period" and that MeHg samples were taken 5 weeks after the last SO_4 addition. Based on the available data, it is estimated that the average porewater temperature for the peatland/wetland studies was approximately 15°C.

For sensitivity analysis, an average annual temperature of 5°C will be assumed for the modelled area based on the reasoning that the primary zones of SO_4 reduction in the waterbodies will be relatively cool areas (e.g., anoxic environments such as hypolimnia, which typically range between 0°C and 10°C, depending on seasonality, water-column depth, mixing depth and related parameters such as transparency, fetch, etc.) and to provide a meaningful contrast with the estimated 15°C temperature of the peatland studies.

In order to estimate the extent to which using data from the studies performed in non-winter months may lead to overestimation of the annual average SO_4-reduction rates, the (relative) SO_4-reduction rates (SRR) will be calculated for temperatures of 15°C and 5°C (based on **Error! Reference source not found.**) and the expected increase in porewater-MeHg concentration (based on **Error! Reference source not found.**) scaled accordingly.

$$SRR_{temp} = 0.065 \times temp^2 + 2.6313 \times temp + 12.702$$

The temperature scaling factor will be applied to the SO_4-MeHg stoichiometric ratio of 0.65 (Table 3) to adjust estimates of change in MeHg efflux

$$F\text{-}MeHg_{(i)} = F\text{-}MeHg\text{-}Bkg \times 0.65 \times SRR_{5°C} \div SRR_{15°C} \times F\text{-}SO_{4(i)} \div F\text{-}SO_4\text{-}Bkg$$

4. Summary

The proposed approach to estimating the increase in water-column MeHg concentrations due to SO_4 loading from the Great Bear Project uses mass-balance modelling to estimate loading and concentrations, water-porewater concentration gradients to estimate vertical fluxes of SO_4 and MeHg, and empirical data from the scientific literature to estimate the relationship between changes in SO_4 loading and MeHg concentrations. The modelling assumes that steady-state, annual-average conditions apply.

The approach comprises the following steps:

1. Ambient flows will be estimated by areal prorating of flows from gauged watercourses.
2. SO_4 loadings and concentrations of each waterbody will be calculated based on annual-average flows and effluent and background SO_4 concentrations.
3. SO_4 influx to sediment porewater will be calculated based on Fick's 1st law of diffusion.
4. MeHg efflux from porewater will be modelled relative to background, based on the increase in porewater SO_4, as per the available studies conducted in peatlands.
5. The increase in water-column MeHg is calculated based on flow and the change in efflux from sediment.

Sensitivity analyses will be performed to assess the quantitative implications of uncertainty in model parameters.

Advanced Exploration Project

Great Bear Resources Ltd.'s (GBR) Response to August 19th, 2025 Letter from MDAG and August 24th, 2025 Letter from Dr. Branfireun

Great Bear Project ECA and PTTW Applications, July 7 and July 24, 2025

#	Comments	Kinross Response
MDAG Letter Dated August 19th 2025		
1. And PTTW comment	*First, the artificial separation between PTTW requirements and ECA requirements heightens the risk that MECP will fail to consider significant issues with the PTTW application that will impact on the ECA. For example, the Great Bear groundwater water model on which the PTTW and ECA are based is critically important, but flawed and unreliable as my past comments have shown. This groundwater model predicts that miners would be working deep underground during Advanced Exploration at the same time that the underground workings would be filled with water to various levels all at the same time. If the Great Bear PTTW were to be approved, the ECA would not have to address this error that invalidates statements made in Kinross' ECA document because it was approved under the PTTW. This groundwater model is discussed further below under Kinross July 24 PTTW Comments.* *My comments have pointed out how the Kinross FeFlow model fails to simulate reality at Great Bear and thus is flawed and unreliable. In turn, Kinross does not respond to and correct its failures, but instead indicates I do not understand how to ignore these failures of its model and to pretend it is working correctly. As I have pointed out before, the Kinross FeFlow model predicts that miners would be working deep underground during Advanced Exploration at the same time that the underground workings would be filled with water to various levels all at the same time. That is what the model and the contours show, but this is impossible because the FeFlow model cannot simulate reality at the Great Bear Project.*	These two comments are being addressed together due to their similarity. The reviewer's initial comment suggesting that the separation of approvals between the PTTW and ECA is artificial is not an issue that can be addressed by Kinross and difficult to understand. The reviewer uses the word "artificial" to describe the use of different regulatory instruments to manage a water taking from a natural environment and the operation and maintenance of treatment facilities. The term artificial is ambiguous as it can mean either produced by human beings or insincere. It is not clear which meaning the reviewer is intending with their comment. The reviewer, although only recently registered as a professional in Ontario, is surely aware the MECP addresses the division with respect to environmental outcomes by assigning the same reviewers to both instruments. The example given by the reviewer in the first paragraph of their quoted comments is a repeat of a previous comment. The reviewer continues to suggest in this paragraph, which he expounds upon in subsequent text, that there are significant issues with the use of a groundwater model, FeFlow to simulate the movement of groundwater in the subsurface towards underground workings. It appears that the reviewer is suggesting that FeFlow, which is a widely used groundwater model for this application and used in hundreds if not thousands of peer reviewed articles to model groundwater, has a fundamental issue such that groundwater models are "flawed and unreliable". The mathematical boundary conditions used in the model were developed to specifically simulate the interface between the saturated rock interface with the underground workings, and do not, as the reviewer claims, "invalidate(s) statements" made by Great Bear Resources. There is no debate within the scientific community about the use of these boundary conditions for these applications. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No

#	Comments	Kinross Response
		additional comment will be provided on this matter.
1.	*Second, Kinross has proposed issuing "updates" for expected contamination during Advanced Exploration including metal leaching and acid rock drainage (ML-ARD), and has issued one update in March 2025. These updates would replace a comprehensive, integrated report estimating future contamination. Kinross has provided these comprehensive, integrated reports for other aspects of the Great Bear Project like the groundwater model mentioned above, but not on environmental contamination and ML-ARD.* *Please note a fundamental concern at Great Bear and all other advanced-exploration projects is the amount and severity of the contamination that the operation would produce and release. There is no comprehensive assessment and estimation of this fundamental concern about future contamination at the Great Bear Project. Thus, there is no way to reliably assess what is needed for safe and proper environmental protection at Great Bear, although advanced exploration at Great Bear has already been designed in detail. This is an environmentally dangerous example of "putting the cart before the horse". It is a false belief that Kinross could later respond literally immediately before any significant environmental damage occurred.* *The 2009 federal ML-ARD Prediction Manual3, which must be complied with in Ontario under the Mine Rehabilitation Code for advanced exploration closure plans, points out that comprehensive and integrated information on future contamination is needed in advance. The reactive approach of "putting the cart before the horse" is rejected in this Manual. Under this Manual, no disturbance such as changing water levels and water flows should be allowed until the comprehensive and integrated information on expected contamination is submitted, reviewed, and approved. Again, Kinross is ignoring these recommendations that are based on standard procedures and best practices.* *The effect of this failure by Kinross can now be seen in Comment A.1 of the Kinross July 7 Comments. Part of this Comment says, "We believe the reviewer [Kevin Morin] has interpreted the numbers of PAG and NPAG humidity cells to represent the distribution of PAG and NPAG rock" in the March 2025 ML-ARD update. This highlights the failure of ML-ARD updates for the Great Bear Project.* *The March 2025 ML-ARD update does not state that the numbers of PAG humidity cells are not representative of PAG percentages at the site. If the numbers are not representative, then this should be stated in the March 2025 update but is not. Instead, the March 2025 update was issued out of context and with no parallel update on the percentages of PAG/NPAG rock. Thus, Kinross expects external people to know internal information that Kinross has not released and updated. In fact, Kinross has released little information on expected contamination and ML-ARD, and thus there is insufficient context for proper environmental protection and sufficient water treatment at the Great*	Great Bear has conducted a comprehensive ML/ARD characterization study for the Project following the guidance of the MEND 2009 manual, per the requirements of the Ontario Mining Act. Results and knowledge gained from these ongoing ML/ARD studies have been incorporated into the AEX Program design to ensure an environmentally acceptable project. This has included early identification of mine rock ML/ARD characteristics and optimization of the study designs to provide better resolution of those characteristics to improve the Project. The ML/ARD study has included releases of information when available, including kinetic testing data, to support regulatory review. The March 2025 Humidity Cell Tests Update document was produced to show the progress of the Project kinetic tests and provide information on key subjects such as metal release rates and lag time to net acid conditions for PAG materials. The intent of that document was clear, and no statements were made regarding volumes of PAG rock in the AEX Program. Our July 7 comment was to point out to the reviewer that the numbers of kinetic tests could not be directly extrapolated to the AEX program rock volume. Information on PAG and NPAG rock volumes and key rock types for the AEX had been previously provided to ANA in other reports. Great Bear Resources committed through the Closure Plan consultation to provide updated geochemical reports the Ministry of Energy and Mines (MEM). We provided the AEX Program ML/ARD assessment report (September 2025) to MEM and the MECP and the AEX Program Water Quality Estimate Update (August 2025) to the MECP The ML/ARD report is approximately 4,000 pages in length and contains a comprehensive compilation of extensive geochemical and mineralogical testing results and interpretations to support the AEX Program development. The water quality estimate utilizes kinetic testing results and site monitoring data, and follows industry standard practices to develop water quality estimates for the AEX Program. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

#	Comments	Kinross Response
	Bear Project. This a failure by Kinross and its consultants to provide detailed and comprehensive information and context for its ML-ARD updates, as illustrated in Comment A.1. *Independent of the PAG/NPAG categories of rock, I reached a much more important conclusion based on the March 2025 ML-ARD update. The information in this update, when scaled up to the full site conditions at Great Bear, indicated water contamination and water-quality degradation during Advanced Exploration would likely be much worse than currently predicted and designed for. This much higher contamination could be to the point that the currently proposed water treatment would fail to properly treat it. Kinross did not contest or disagree with this in its Kinross July 7 Comments.* *Therefore, water quality during and after Advanced Exploration will be worse than currently predicted and designed for, and the currently proposed water treatment will likely be insufficient and thus release additional contamination.*	
2.	*Third, Comment A.6 in the Kinross July 7 Comments states in part, "sulphate concentrations will meet background levels at the end of the mixing zone." Other experts for Grassy Narrows First Nation are addressing the impacts and effects of sulphate. My point was that there would be various forms of toxicity within the mixing zone no matter how long it was, which Kinross again ignored by simply addressing the end of the mixing zone.* *It is easy to envision adverse environmental effects greater than what is currently predicted by Kinross. For example, the river sediments at the bottom near the contaminated-water discharge will be exposed to this contamination and will adsorb some of it through time. Thus, local sediment quality degrades. Occasionally, such as during high flows, this contaminated sediment will be flushed downstream into pristine areas where it can contaminate sediment and aquatic life in its new location. As another example, benthic organisms exposed to contamination in the mixing zone would eventually die and can be carried downstream into pristine areas, releasing contamination to the pristine areas.* *Therefore, the mixing zone in the Chukuni River for Great Bear's contaminated water can produce additional, long-term contamination farther downstream not evaluated by Kinross to date. Kinross July 7 response of "sulphate concentrations will meet background levels at the end of the mixing zone" does not recognize or address this downstream contamination.*	The technical basis for approval of the ECA ISW and anticipated conditions therein for the proposed AEX Program is sufficient and has occurred as per the appropriate regulatory regime in Ontario, as per our previous responses. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
Dr. Brian Branfireun Letter Dated August 24th 2025		
Comment B.1	*In response to my concerns about baseline data deficiencies, inappropriate analytical approaches, and selective flow analyses to overstate the assimilative capacity of the Chukuni River, the Proponent simply indicates that these issues were 'addressed' in prior responses. In my opinion, this is not the case. As indicated above, prior responses from the Proponent have chosen to either simply 'disagree' with my identification of deficiencies in the permit application based on factual information presented in their own documents, or lean on purported compliance with MECP regulations. My opinion stands that there is virtually no usable background data on sulphate, mercury, and methylmercury for the project area. The response here that refers to prior insufficient responses only serves to bury the scientifically unsupportable justifications and explanations deeper in the record.*	The reviewer's assertion that there is "virtually no usable background data on sulphate, mercury, and methylmercury" is demonstrably false and mischaracterises both the scope and quality of the baseline dataset compiled for the Chukuni River and other local area waterbodies. For example, over three years of monthly sulphate monitoring data have been collected across three stations on the Chukuni River (CR-REF, CR-FDP, CR-DS), with 94% of observations above

#	Comments	Kinross Response
	In response to my determination that the project may result in significant increases in sulphate in the Chukuni River, the Proponent chose to inexplicably respond by stating that "We have demonstrated the differences between the conditions and factors measured in the Riverbank Study and the conditions in the aquatic system downstream of the project (English River system). It is not appropriate to apply the riverbank study to the methyl mercury patterns in the entire English Wabigoon system, let alone the system downstream of the Project." The Riverbank study has nothing to do with my calculations of what potential sulphate concentrations may be in the Chukuni River, so the intention of this response is unclear. If the intention is to imply that the receiving waterbody and those downstream cannot support mercury methylation, then this is factually untrue since MECP fish monitoring data indicate otherwise, with consumption advisories for methylmercury in fish in the public record that I have referred to previously. If the intention is to imply that sulphate reduction controls mercury methylation in the Wabigoon River (consistent with 30 years of scientific understanding) but that some other process other than sulphate-reduction controls methylation in the English River system, then I would be very curious to know what scientific breakthrough the Proponents have made in this regard. In my opinion they in no way "have demonstrated the differences between the conditions and factors" in prior documents, as indicated.	detection limits. Since 2022, detection limits have consistently ranged between 1 and 2 mg/L, and all 2021 observations—collected using a different analytical method—were also above detection limits. The reviewer's claim that the Proponent has relied on "selective flow analyses" to overstate assimilative capacity is similarly unfounded. The modelling approach explicitly evaluated the full range of permitted discharge conditions, including the highly conservative 7Q20 low-flow scenario as is required by MECP Policy B-1-5. The reviewer's claim that baseline sulphate concentrations will be exceeded beyond the mixing zone in the Chukuni River is demonstrably false and misrepresents both the regulatory framework underpinning the anticipated ECA ISW and Great Bear Resources' commitments to environmental protection. The proposed conditions of the ECA ISW include sulphate discharge limits specifically designed to meet background concentrations at the edge of a small mixing zone, in full alignment with Ontario's regulatory standards for environmental protection. Calculations were reviewed and confirmed as accurate by Senior Technical Staff at the MECP. Water quality modelling completed by Great Bear Resources, using the proposed effluent limits for sulphate, shows that baseline sulphate concentrations in the Chukuni River are maintained under all permitted discharge conditions, including the theoretical maximum discharge co-occurring with the low-flow 7Q20 event—a highly conservative and unlikely scenario explicitly evaluated in the assessment The reviewer has continued to dismiss empirical data, the technical realities of the AEX Program, and the regulatory standards that govern it. Great Bear Resources has responded comprehensively and transparently to all concerns raised. Reiterating unsupported claims does not constitute a valid scientific critique, and no additional comment will be provided on this matter.
Comment B.2	*In response to my calculations of potential river sulphate concentrations using the MECPs sulphate effluent limit explicitly stated in the ECAs Summary of ECA Conditions Under Consideration, the Proponents response is "We disagree that the proposed ECA will allow for a sulphate increase of 35% in the Chukuni River." As is often the case in the Proponents responses, this 'disagreement' is unsubstantiated. I used the numeric criteria exactly as stated in the ECA. The mathematics is quite simple – one typically does not "disagree" with the result of a numerical calculation without demonstrating an error. The ECA will most certainly allow an increase of this magnitude above natural background. There can also be no disagreement about what the definition of natural background concentration is, as it is the concentration of a constituent that would be found upstream of ANY pollution source. As I indicated in my prior memo, the Proponent themselves acknowledge substantial upstream contributions of sulphate from other operations – as such sulphate concentrations measured in the Chukuni River just upstream from the proposed project are several fold higher than natural background concentrations. The Proponents repeated attempt to paint the receiving water system as being not sensitive to additional sulphate loading leading to increased mercury methylation defies decades of scientific consensus and publically available data. The implication that the underlying mechanisms that contributed to the findings of the Riverbank sediment study were somehow unique and not applicable elsewhere is wholly unsupportable.*	The reviewer's claim that baseline sulphate concentrations will be exceeded beyond the mixing zone in the Chukuni River is demonstrably false and misrepresents both the regulatory framework underpinning the anticipated ECA ISW and Great Bear Resources' commitments to environmental protection. The proposed conditions of the ECA ISW include sulphate discharge limits specifically designed to meet background concentrations at the edge of a small mixing zone, in full alignment with Ontario's regulatory standards for environmental protection. Calculations were reviewed and confirmed as accurate by Senior Technical Staff at the MECP. Water quality modelling completed by Great Bear Resources, using the proposed effluent limits for sulphate, shows that baseline sulphate concentrations in the Chukuni River are maintained under all permitted discharge conditions, including the theoretical maximum discharge co-

		occurring with the low-flow 7Q20 event—a highly conservative and unlikely scenario explicitly evaluated in the assessment. The technical basis for approval of the ECA ISW and anticipated conditions therein for the proposed AEX Program is sufficient and has occurred as per the appropriate regulatory regime in Ontario, as per our previous responses. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
Comment 3	*In response to my assertion that the Conditions of the ECA are not protective with respect to sulphate and mercury methylation, the Proponent again chooses to disagree, stating that "subject to stringent conditions that include sulphate discharge limits designed to meet background concentrations at the end of the approved mixing zone. These limits were developed in accordance with Ontario's regulatory framework to ensure protection of the receiving environment.". I demonstrated quite plainly that the numerical effluent criteria in the Conditions under Consideration of the ECA would allow for exceedances of sulphate well above natural background, and that these exceedances could be quite substantial around certain flow thresholds.* *The Proponent then goes on to state that "In addition, a detailed monitoring and adaptive management program has been collaboratively developed with Wabauskang and Lac Seul First Nations, whose traditional territories include the project area. This program provides for proactive oversight and mitigation to address any unforeseen changes in water quality and reflects a shared commitment to environmental protection.". We are expected to take those statement at face value without any documentary evidence that I am aware of. It is inferred that this program concerns sulphate and changes to mercury methylation, however this is not stated explicitly.* *What is notable are the concerns that I raised in my July 7 memo that the Proponent chose* ***not*** *to respond to. There is no response to my concerns about the Proponents weak justification to the MECP to not treat effluent for sulphate, no response to my identification of Mr. MacDonnell's (Kinross) acknowledgement of upstream contributions of sulphate from other mines for decades (thus undermining the assertion that river sulphate concentrations immediately upstream of the proposed project are a representative natural background), and no response to Mr. MacDonnell's completely unsupportable statement that despite the decades of mine sulphate discharge "there is no evidence of any material change in mercury concentrations in fish tissue as a result.".* *My conclusions are unchanged. The revised PTTW and revised ECA make no movement toward protecting the downstream environment from enhanced mercury methylation and increased mercury concentrations in fish because they do not fundamentally address the source of sulphate nor effectively limit the release of sulphate to a receiving environment that is sensitive to mercury contamination.*	The reviewer's claim that baseline sulphate concentrations will be exceeded beyond the mixing zone in the Chukuni River is demonstrably false and misrepresents both the regulatory framework underpinning the anticipated ECA ISW and Great Bear Resources' commitments to environmental protection. The proposed conditions of the ECA ISW include sulphate discharge limits specifically designed to meet background concentrations at the edge of a small mixing zone, in full alignment with Ontario's regulatory standards for environmental protection. Calculations were reviewed and confirmed as accurate by Senior Technical Staff at the MECP. Modelling completed by Great Bear Resources, using the proposed effluent limits for sulphate, shows that baseline sulphate concentrations in the Chukuni River are maintained under all permitted discharge conditions, including the theoretical maximum discharge co-occurring with the low-flow 7Q20 event—a highly conservative and unlikely scenario explicitly evaluated in the assessment. The reviewer's dismissal of monitoring and adaptive management program is unfounded. This program, created in partnership with the MECP, explicitly includes provisions for monitoring sulphate and mercury methylation, with mechanisms for proactive mitigation should any adverse trends emerge. Assertions to the contrary are not supported by the evidence and do not reflect the regulatory environment or technical realities of the AEX Program. All data collected to date show that sulphate levels are low. The only known, potentially applicable, treatment technology to further reduce expected sulphate concentrations in contact water quality is Reverse Osmosis (RO). RO systems present significant operational challenges, particularly related to brine and waste management. Implementing a brine management system to address a risk that has not been demonstrated would introduce unnecessary environmental and operational burdens. Based on the feedwater quality to the AEX Effluent Treatment Plant (ETP), expected to contain low levels of sulphate, use of a sulphate removal system such as RO is not warranted during the AEX phase. Background concentrations of sulphate will be met in the Chukuni River with AEX effluent discharges as described

		above. The reviewer has continued to dismiss empirical data, the technical realities of the AEX Program, and the regulatory standards that govern it. Great Bear Resources has responded comprehensively and transparently to all concerns raised. Reiterating unsupported claims does not constitute a valid scientific critique. The technical basis for approval of the ECA ISW and anticipated conditions therein for the proposed AEX Program is sufficient and has occurred as per the appropriate regulatory regime in Ontario, as per our previous responses. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

KINROSS Great Bear

Great Bear Gold Project

August 30, 2025, Source Environmental Associate Inc. Evaluation of Great Bear Resources' Responses to Summary Comments on AEX ECA

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
C.1	The proponent should submit a finalized version of the water quality model report that incorporates all prior review comments. A revision history log should accompany the final document to clarify all changes made during the review process. The updated version should serve as the technical basis for approval assessments and ECA conditions.	Provided a response on June 18, 2025, to comments received by ANA on April 11, 2025. Also addressed by the GBR response letter sent February 5, 2025, regarding ANA letter dated September 6, 2024.	Source previously reviewed Great Bear's June 18, 2025, response, including Attachment 1 (Water Quality Model memo). Source's July 7, 2025, memorandum reflects the review conducted on the June 18 response and identifies that the draft WQM remains incomplete. The WQM report (included as Attachment 1), titled "Advanced Exploration Program (AEX) Water Quality Estimate Update, Great Bear – Draft" is dated February 1, 2024, despite the submission of follow-up materials and prior feedback from MECP, the Ontario Ministry of Energy and Mines (MINES), and ANA. The use of the same draft document after more than a year and multiple comment rounds indicates a lack of responsiveness to comments provided. Without receiving an updated version, reviewers cannot verify which data, assumptions, or scenarios have been updated in response to previous feedback. As such, this comment has not been addressed. It is noted that GBR response letter on February 5, 2025 (filename: 2025 02 06 Great Bear Response to ANA AEX_ECA_7 July 2024_Aug2024 4923-4663-7335 1) is merely a copy of August 1, 2024, Kinross response to Source's previous comments. Source has already provided responses to the August 1, 2024, Kinross Response. For ease of reference, Source's evaluation of Kinross' August 1, 2024, response is attached herein.	The technical basis for approval of the ECA ISW and anticipated conditions therein for the proposed Advanced Exploration Program (AEX) is sufficient and has occurred as per the appropriate regulatory regime in Ontario, as per our previous responses. Anticipated ECA ISW conditions include extensive follow-up monitoring, triggers for adaptive management, and contingency measures. Key technical supporting materials submitted, listed below for ease of reference (and within our previous responses) collectively demonstrate that the modelling framework has been updated since February 2024, including a recent update in August of 2025. An additional update to the water quality modelling at this stage—prior to the commencement of AEX Program activities—would not yield improvements to the engineering design of the proposed works, the conditions of the ECA ISW, or the level of protection afforded to the receiving environment beyond what has already been proposed. Great Bear Resources respectfully disagrees with the reviewer's characterisation; the apparent disagreement between Great Bear Resources and the consultants representing ANA does not equate to a lack of responsiveness by Great Bear Resources. As per our previous responses, Great Bear Resources has provided multiple rounds of updated technical materials that directly address reviewer comments and incorporate new data since the submission of the original draft application in 2022. These include: – WSP 2024. *Response to Dr. Branfireun Letter Concerning the Potential Effects of Proposed Discharge to the Chukuni River, Great Bear AEX ECA ISW Application*. October 2024. – Great Bear 2025. *ANA Comments: Review of the*

We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.2	The proponent should develop a consolidated water quality model that addresses all mine phases: construction, exploration, active closure, passive closure, and post-closure. The model should clearly define	Provided a response on June 18, 2025, to comments received by ANA on April 11, 2025. Also addressed by the GBR response letter sent February 5, 2025, regarding ANA letter dated September 6, 2024.	Similar to Comment 1, the June 18, 2025, response and Attachment 1 (WQM memo) have already been reviewed by Source as part of July 7, 2024, technical memorandum. The provided WQM does not meet the requirement for a consolidated model covering all mine phases and remains a draft document. The WQM memo provided appears to only address the exploration (operational) phase of the Great Bear AEX Program. It does not include predictions for the construction, active closure, passive closure, or post closure phases, each of which involves unique water quality risks and management requirements. While water quality estimates are included in Appendix M of the Great Bear AEX Program Closure Plan for some later phases	Please note, this is a 5-year advanced exploration program, it is not a mine, and is not subject to the *Federal Impact Assessment Act*. The technical basis for approval of the ECA ISW is sufficient and has occurred as per the appropriate regulatory regime in Ontario; please see response to Comment C.1. The technical supporting materials for the ECA ISW application are appropriately tailored to the specific activities to be authorised under that approval. Importantly closure-related activities are not the scope of an ECA ISW and are addressed under separate regulatory processes (in the Closure Plan approved by MINES), Please also refer as per our previous responses, including those distributed on June 18, 2025, to

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
			(specifically passive- and post-closure), these are not integrated into the main modeling framework. A single, consolidated model report that addresses all project phases represents is requested. This comment therefore remains outstanding. The model should clearly define: • Phase-specific inputs (e.g., water sources, contaminant loading assumptions); • Evolving water management strategies (e.g., treatment system design changes, pond retention times); • Changes in drainage, hydrogeology, and contaminant transport pathways over time; and • Projected effluent quality under realistic operating and climate scenarios for each phase. All outputs should be used to inform long-term compliance planning, effluent limit setting, and monitoring program design. This full-phase modeling approach is necessary to ensure environmental protection throughout the life of the project. It is noted that GBR response letter on February 5, 2025 (filename: 2025 02 06 Great Bear Response to ANA AEX_ECA_7 July 2024_Aug2024 4923-4663-7335 1) is merely a copy of August 1, 2024, Kinross response to Source's previous comments. Source has already provided responses to the August 1, 2024, Kinross Response. For ease of reference, Source's evaluation of Kinross' August 1, 2024, response is attached herein.	comments received by ANA on April 11, 2025. Also addressed by the GBR response letter sent February 5, 2025, regarding ANA letter dated September 6, 2024. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.3	In comparable jurisdictions such as British Columbia and Yukon, the proponents are typically required to provide underground specific source terms and node that significantly influences the water quality within the site. These model nodes are	We remind the reviewer the Project is located in Ontario. Our project is designed to comply with applicable law. Great Bear has previously provided a response to ANA regarding water	As outlined in Source's July 7, 2025, technical memorandum, this review comment was based on the evaluation of the Water Quality Model memo submitted as part of Great Bear's June 18, 2025, response. The issues raised remain unresolved because the information is fragmented across multiple submissions and has not been integrated into a consolidated Water Quality Model	Please see responses to C.1. and C.2.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	expected to inform treatment system design and regulatory limits. Moreover, during closure or temporary shutdown, flooded workings may mobilize legacy oxidation products from PAG zones or wall rock. These conditions can result in contaminant pulses that require mitigation planning, contingency treatment, and monitoring frameworks.	quality of the underground mine water on August 1, 2024. Also addressed by the GBR response letter dated February 5, 2025, in response to ANA letter dated September 6, 2024. Regarding ANA's concerns about water quality predictions, (letter dated April 11, 2025), GBR responded to ANA on June 18, 2025.	report. Without a unified document, it is difficult to assess how underground-specific source terms, model nodes, and treatment system considerations are incorporated into the overall water balance and quality predictions. This comment therefore remains outstanding. The following request was previously made in July 7, 2025, technical memorandum: • The proponent should provide a comprehensive evaluation of expected underground mine water quality. This assessment should be based on: • Site-specific geochemical characterization of underground rock types, including PAG zones; • Consideration of mine development methods, blasting residues, oxygen ingress, and water-rock interaction under dewatered and reflooded conditions; and • Modeling of contaminant release during active pumping and during reflooding events (e.g., shutdown or post closure scenarios). The predictions should be specific to each mine phase and aligned with mine development timelines. The model should also assess the implications of this water quality on treatment performance. It is noted that GBR response letter on February 5, 2025 (filename: 2025 02 06 Great Bear Response to ANA AEX_ECA_7 July 2024_Aug2024 4923-4663-7335 1) is merely a copy of August 1, 2024, Kinross response to Source's previous comments. Source has already provided responses to the August 1, 2024, Kinross Response. For ease of reference, Source's evaluation of Kinross' August 1, 2024, response is attached herein.	
C.4	The WQM report does not account for nitrogen-based contaminants (ammonia, nitrite, and nitrate) that are commonly introduced into the mine area as residues from blasting	A response was provided to ANA on February 5, 2025, in response to concerns raised about nitrogen species in a letter from ANA dated September 6, 2024.	Similarly, the July 7, 2025, technical memorandum identified that nitrogen-based contaminants introduced by blasting agents have not been adequately accounted for in the draft Water Quality Model. Kinross' response provided in the February 5, 2025, submission only states	We believe the reviewer's summary of the response by Great Bear regarding this topic is innacurate. A response concerning identifying parameters of potential concern, as well as potential effects regarding potential nitrogen loadings was provided July 2025, February 2025 and

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	agents. This omission represents a notable gap given that blasting is a planned activity during underground development.		that effluent criteria have been developed in accordance with MECP Policy B-1-5, and for parameters including nitrate and nitrite would be subject to the Surface Water Monitoring Program. Source reiterates that this response does not address the comment that the WQM should account for all nitrogen-based contaminants including ammonia, nitrate, and nitrite that are commonly introduced from the blasting activities. A consolidated and updated Water Quality Model is required to demonstrate how nitrogen species will be predicted and managed within the overall water quality and balance framework. This comment remains unaddressed. Moreover, the model contains no discussion of the type of blasting materials, volumes used, leachability, or potential release pathways for nitrogen species in site runoff or seepage water. The proponent should revise the WQM report to include a quantitative assessment of nitrogen species, specifically ammonia, nitrate, and nitrite, resulting from blasting activities. This should include: • Identification of explosive types and compositions proposed for use. • Estimated volumes of explosives to be used during the AEX Program. • Leaching potential of nitrogen compounds based on site-specific or literature-derived data. • Modeling of nitrogen species release from the underground working, ore and mine rock stockpiles; and • Evaluation of nitrogen removal performance in the ETP under expected and conservative load conditions. If nitrogen species are found to present a risk to effluent quality or receiving waters, the proponent should identify appropriate mitigation measures such as explosive	September 2024. Specifically, from that response (brackets added for additional clarity): – "Effluent criteria (as per MECP Policy B-1-5) are j**ust one aspect** of the regulatory approach in the ECA ISW application. The Surface Water Monitoring Program includes threshold criteria (mg/L) that trigger adaptive management for all parameters with Water Quality Guidelines for the Protection of Aquatic Life (WQG PAL). The approach is to maintain WQG PAL, or background water quality, as applicable, in the receiving environment downstream of a short mixing zone throughout the AEX Program (as well as in Dixie Creek and other monitored waterbodies proximate to the AEX footprint as outlined in the Surface Water Monitoring Plan). Consequently, all water quality parameters with WQG PAL (this includes nitrogen species) are regulated in relation to effluent discharge (and AEX Program activities, like blasting) and no parameters are missing or omitted from regulation, contrary to the reviewer's suggestion. This comprehensive strategy indicates that all relevant parameters are considered in the ECA ISW and are carefully managed to protect surface water quality and aquatic ecosystem health throughout the AEX Program." While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
			loading control, targeted capture systems, or ammonia/nitrite/nitrate-specific treatment technologies.	
C.5	The water quality model lacks a sensitivity analysis. The water quality model includes numerous assumptions related to hydrological inputs, geochemical conditions, and contaminant loadings that are inherently uncertain. While the proponent includes both expected and conservative geochemical source terms, there is no indication that variability in factors such as climate conditions, streamflow, groundwater inflows, or operational changes over time were tested to understand how the model would respond to these fluctuations. The proponent should complete and clearly document a sensitivity analysis as part of the water quality modeling. This analysis should explore how model outputs respond to a range of uncertain inputs, including wet and dry flow conditions, the upper and lower bounds of updated geochemical source terms, seasonal changes such as snowmelt pulses or late-summer low flows, and projected climate change impacts on site hydrology and contaminant transport.	The water quality model is appropriately conservative and consistent with standard industry practice for a project at the advanced exploration (AEX) stage. Great Bear has committed to updating the model every three years and will compare monitoring results against model predictions as part of regular compliance reporting. It is important to emphasize that any model refinements made prior to approval of the Environmental Compliance Approval for Industrial Sewage Works (ECA ISW) would not alter the mitigation measures, effluent limits, or follow-up monitoring programs already embedded in the AEX Program design. These components have been developed in coordination with the MECP using conservative assumptions to protect against the full range of potential conditions. As is best practice, multiple layers of mitigation and contingency have been incorporated to manage uncertainty, including: • Lined waste rock storage areas and lined contact water ponds to limit contaminant transport. • Flexible, modular water	As outlined in Source's July 7, 2025, technical memorandum, this review comment specifically requested a sensitivity analysis to evaluate how the water quality model responds to a range of uncertain inputs (e.g., wet and dry flow conditions, updated geochemical source terms, seasonal events like snowmelt or late-summer low flows, and projected climate change impacts). The proponent's response reiterates that the current model is "appropriately conservative" and consistent with industry practice but does not provide or commit to a sensitivity analysis. The "conservative case" used in the WQM memo, Advanced Exploration Program (AEX) Water Quality Estimate Update, Great Bear – Draft" is dated February 1, 2024, only accounts for purportedly conservative geochemical source term. While conservative inputs can offer some margin of safety, they do not replace the need to evaluate system behavior under multiple plausible scenarios. Sensitivity testing is a standard component of robust water quality modeling. Without it, the Proponent's claim that "these components have been developed in coordination with MECP using conservative assumptions to protect against the full range of potential conditions" cannot be substantiated. A conservative source term alone does not capture the combined variability of hydrologic, climatic, and operational factors that can significantly influence contaminant transport and water quality outcomes. Lastly, the response also cites a submission dated September 5, 2025; however, this date is not possible as it is in the future. It is likely referring to the September 5, 2024 submission. To allow proper review, please provide the referenced September 5, 2024 document for verification and context.	The technical basis for approval of the ECA ISW is sufficient and has occurred as per the appropriate regulatory regime in Ontario; please see response to Comment C.1 regarding water quality modelling and responses provided and geochemical characterisation, including the updated water quality from August 2025. Consistent with best practice, the AEX Program incorporates multiple layers of mitigation and contingency to manage any uncertainty and minimise potential interaction with the receiving environment. The planned measures exceed industry standards for a typical advanced exploration and include: – Full containment of all waste rock storage areas and collection ponds and use of engineered liners; – Classification of overburden piles as contact water sources, with all associated runoff directed to water treatment systems; – Deployment of flexible, modular water treatment systems designed to adapt to changes in influent chemistry; – Provision of dedicated contingency storage to accommodate variable flow volumes and unanticipated conditions. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
		treatment systems capable of adjusting to changes in influent chemistry. • Dedicated contingent storage to accommodate variable flow volumes or unexpected conditions. • Given the use of conservative inputs, proven • mitigation measures, and the commitment to regular model updates, the approach provides a robust and defensible foundation for permitting decisions. • Responses addressing concerns regarding effluent limit development were provided to ANA on August 1, 2024, and September 5, 2025.		
C.6	If PoPCs are not identified and screened, there is a high risk that key contaminants may be omitted from both the predictive model and subsequent ECA limits. This can lead to discharge of unregulated contaminants, underestimation of environmental risks, and inadequate design or monitoring of treatment systems. Recommendation: The proponent should provide an assessment of PoPCs based on the modeled predictions comparing with baseline water quality data and applicable regulatory guidelines and site-specific consideration. This process should	Responses addressing concerns regarding effluent limit development were provided to ANA on August 1, 2024, and September 5, 2025.	The issue of missing screening analysis for Parameters of Potential Concern (PoPCs) has been raised repeatedly, including in Source's July 7, 2024, and July 7, 2025, memoranda. The August 2024 response does not address the fundamental concern because: • No PoPC screening analysis or results have been provided, preventing verification of completeness. • Effluent criteria were derived from preliminary geochemical and baseline studies, which is not a substitute for a systematic PoPC assessment. • It remains unclear how geochemical test results, environmental baseline data, and site water quality model considerations were integrated into identifying PoPCs.	The technical basis for approval of the ECA ISW is sufficient and has occurred as per the appropriate regulatory regime in Ontario; please see response to Comment C.1 Great Bear has sufficiently addressed the fundamental concern regarding protection of the surface water environment during the AEX Program. For example, as per the response provided on August 1, the approach is to maintain WQG PAL (or background water quality, as applicable) in the receiving environment downstream of a short mixing zone as well as within Dixie Creek/surrounding waterbodies throughout the AEX Program. Consequently, all water quality parameters with WQG PAL are regulated in relation to the AEX Program vis a vis the proposed effluent criteria, planned rock management and water mitigation measures (e.g. liners, treatment) and trigger criteria/thresholds for adaptive

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	identify which parameters have the potential to exceed background concentrations, pose ecological or human health risks, or require active management through treatment or monitoring. The assessment should also provide justification for any constituents excluded from the model. This PoPCs assessment forms a basis		• The approach described relies heavily on the assimilative capacity of the Chukuni River rather than demonstrating how Best Achievable Technology would reduce effluent levels. • Potential contaminants of concern such as (nitrate, nitrite, aluminum, antimony, cadmium, chromium, cobalt, iron, mercury, selenium, silver, and chloride), as described in Comment 9 herein appear to be omitted from the proposed effluent discharge limits. Lastly, the response also cites a submission dated September 5, 2025; however, this date is not possible as it is in the future. It is likely referring to the September 5, 2024, submission. To allow proper review, please provide the referenced September 5, 2024, document for verification and context.	management as presented in the Surface Water Monitoring Program; no parameters are missing or omitted from regulation, contrary to the reviewer's suggestion. This comprehensive strategy indicates that all relevant parameters are considered in the ECA ISW and are carefully managed to protect surface water quality and aquatic ecosystem health throughout the AEX Program. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.7	The final AEX ECA should revise the effluent discharge limits to consider the minimum protection levels proposed in Table 1. If any parameters remain unchanged from the original MECP or Proponent submission, MECP should provide a technical rationale for their exclusion or justification for the selected limit values. Revised effluent discharge limits should be circulated to ANA and other reviewers for review and comment prior to the issuance of any ECA decision.	Great Bear provided a response regarding effluent limits to ANA in a letter sent February 5, 2025, in response to ANA comments dated September 6, 2024.	It is noted that GBR response letter on February 5, 2025 (filename: 2025 02 06 Great Bear Response to ANA AEX_ECA_7 July 2024_Aug2024 4923-4663-7335 1) is merely a copy of August 1, 2024, Kinross response to Source's previous comments. Source has already provided responses to the August 1, 2024, Kinross Response. For ease of reference, Source's evaluation of Kinross' August 1, 2024, response is attached herein. For ease of reference, a summary of those deficiencies is provided here: • **Criteria largely unchanged:** With the exception of adding a sulfate criterion, the effluent limits under consideration remain essentially unchanged from earlier drafts, despite multiple review rounds. • **Reliance on dilution rather than treatment:** The proposed approach continues to allow discharge up to provincial receiving-environment water quality guidelines after dilution in the Chukuni River, rather than setting protective,	Please refer to response provided to C.1.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
			end-of-pipe treatment-based criteria. • **Key contaminants omitted:** Several PoPCs identified by Source remain absent from the proposed effluent criteria (e.g., nitrate, nitrite, aluminum, antimony, cadmium, chromium, cobalt, iron, mercury, selenium, silver, and chloride). In the absence of regulatory limits, these contaminants could be discharged without constraint, leading to serious ecological or human health impacts. • **Overly permissive limits:** For certain metals where limits are proposed, the thresholds are **orders of magnitude higher** than levels known to cause impacts and far above limits applied in other jurisdictions or projects. Such levels would not ensure protection of aquatic life or downstream users. • **Risk to environment and human health:** Taken together, these omissions and elevated criteria represent a risk of harm to aquatic ecosystems and to human consumers of fish. For these reasons, the February 5, 2025, GBR submission does not substantively address Source's recommendation that the final AEX ECA adopt the minimum protection levels recommended in Source's September 5, 2024, memorandum. Revised effluent discharge limits should be circulated to ANA and other reviewers for comment prior to ECA issuance.	
C.8	The minimum protection levels proposed in Table 1 should apply equally to discharges to ground. The parameter list for the low point drains should be expanded to include all PoPCs identified. Revised effluent discharge limits should be circulated to ANA and other reviewers for review and comment prior to the issuance of any ECA decision.	Responses addressing concerns regarding effluent limit development were provided to ANA on August 1, 2024, and September 5, 2025.	This review comment was first raised in Source's July 7, 2025, memorandum following our review of the "Summary of ISW ECA Conditions Under Consideration" document received in June 2025. The proponent's statement that responses were provided in 2024 does not address this new comment, as the issue had not been previously raised. Source's comment is further explained in Comment 8 of July 7, 2025, technical memorandum. Specifically, the	As per the most recent ECA ISW submission, there are planned discharges to ground under normal operating conditions. PWQO will apply to low point drains in the event pipeline maintenance is required.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
			comment requested that the minimum protection levels in Table 1 apply equally to discharges to ground, that the parameter list for the low point drains include all identified PoPCs, and that revised effluent discharge limits be circulated to ANA and reviewers for input prior to any ECA decision. These points remain outstanding and were not addressed in the cited earlier responses. Lastly, the response also cites a submission dated September 5, 2025; however, this date is not possible as it is in the future. It is likely referring to the September 5, 2024, submission. To allow proper review, please provide the referenced September 5, 2024, document for verification and context.	
C.9	Discharge limit proposed is 10 times higher than the acute BC WQG and PWQO, and 100 times higher than the background Chukuni River WQ. Source is concerned that the Proponent has proposed effluent limits based on achieving water quality guidelines for the protection of aquatic life (WQG PAL) after dilution in the Chukuni River, rather than at the end-ofpipe. As stated in our earlier memorandum, proponents do not have the inherent right to discharge pollutants up to receiving environment guideline thresholds, especially when better treatment is technically achievable. In addition, several PoPCs identified by Source were omitted from the Proponent's proposed effluent limits, and no rationale was provided for these exclusions. In the absence of a robust water quality model, effluent discharge limits should adopt a precautionary approach and minimize the risk of contaminant release to the receiving environment. To this end, it	We would like to remind the review the Project is located in Ontario, and the discharge limits were derived within the policies and framework of the Ministry of Environment and Parks in Ontario. Great Bear has previously provided responses regarding effluent limits to ANA on August 1, 2025, and February 5, 2025.	As stated, discharge limit proposed is 10 times higher than the acute BC WQG and Ontario Provincial Water Quality Objective (PWQO) and 100 times higher than the background Chukuni River water quality. Acute BC WQG is also provided, which is at the same concentration as Ontario's WQG, to illustrate that the proposed discharge limits substantially exceed both provincial and background water quality levels. The response cites a submission dated August 1, 2025; however, assuming this is intended to reference the August 1, 2024, submission, the response states that effluent criteria have been developed in accordance with MECP Policy B-1-5, and that the surface water monitoring program is placed as adaptive management. As stated in previous Source's responses (September 5, 2024), Source maintains that adaptive management is not a replacement for protective effluent criteria limits. Furthermore, MECP B-1-5 policy is clear that "A mixing zone is, under no circumstances, to be used as an alternative to reasonable and practical treatment." Standard treatment technology is available and implementable for the parameters listed in column 1. Effluent criteria limits should reflect the reasonable ability of treatment to remove parameters from effluent as well as site-specific considerations related to bioaccumulation, human exposure, cumulative impacts, and other	It appears the reviewer may be unfamiliar with the regulatory processes for approval of advanced exploration activities in Ontario. Effluent criteria for the AEX Program were developed based on the calculated assimilative capacity of the Chukuni River, assuming a conservative scenario in which maximum discharge volumes coincide with low-flow conditions (7Q20), in accordance with MECP Policy B-1-5. This approach ensures that water quality objectives for the protection of aquatic life (long-term exposure) are met downstream of a defined, small mixing zone. For parameters such as arsenic and sulphate, baseline concentrations were used as the applicable benchmarks. It is important to emphasise that the simultaneous occurrence of both maximum discharge volumes and 7Q20 low-flow conditions is highly unlikely. Under average or expected operating conditions—characterised by lower discharge volumes and higher ambient flows—receiving water quality is anticipated to be significantly better than the 7Q20 modelled scenario. This further reinforces the protective nature of the proposed effluent criteria. This rationale and supporting technical basis have been communicated to ANA on multiple occasions, including in our responses dated 1 August 2025 and 5 February 2025, where detailed explanations of the effluent limit derivation and underlying assumptions were provided.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	is recommended that the following omitted PoPCs be included in the final effluent discharge limits: nitrate, nitrite, aluminum, antimony, cadmium, chromium, cobalt, iron, mercury, selenium, silver, and chloride.		ecological risks, rather than relying on the assimilative capacity of the receiving water body. The proposed discharge limits are far higher than levels treatment technology can reasonably treat and do not account for these site-specific risk pathways. As such, this comment has not been addressed. Lastly, the response also cites a submission dated September 5, 2025; however, this date is not possible as it is in the future. It is likely referring to the September 5, 2024, submission. To allow proper review, please provide the referenced September 5, 2024, document for verification and context.	While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.10	The water quality model does not appear to reflect the updated geochemical predictions based on recent MLARD testing. According to a review by Dr. Kevin Morin (Great Bear Mining Project – MDAG Review of New ECA-Related Documents for	These concerns were raised by ANA in letters dated July 7, 2024, and September 6, 2024. GBR addressed these concerns in our technical responses sent February 5th, 2025. ANA raised the same concern again	Comments in relation to the appropriateness of geochemical assessment is referred to Dr. Kevin Morin's follow-up responses. However, the latest WQM report, titled "Advanced Exploration Program (AEX) Water Quality Estimate Update, Great Bear – Draft" is still dated February 1,	Please refer to response to Comment C.1. The most recent water quality update occurred in August 2025.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	Advanced Exploration, July 2025), the proportion of underground rock classified as potentially acid generating (PAG) may be as high as 70%, approximately double the value assumed in earlier assessments. This discrepancy raises concerns about the validity of the model's underlying assumptions and the absence of a sensitivity test to explore the implications of this updated geochemical context.	in a letter sent April 25, 2025, GBR subsequently provided a response in our June 12th, 2025, technical responses	2024. Source is not aware of any update to the water quality model since February 1, 2024, and it remains uncertain how these concerns have been addressed. As such, this comment has not been addressed.	
C.11	The water quality model lacks a sensitivity analysis. The water quality model includes numerous assumptions related to hydrological inputs, geochemical conditions, and contaminant loadings that are inherently uncertain. While the proponent includes both expected and conservative geochemical source terms, there is no indication that variability in factors such as climate conditions, streamflow, groundwater inflows, or operational changes over time were tested to understand how the model would respond to these fluctuations. Although the water balance model report considers wet and dry scenarios, those variations have not been carried through to the water quality predictions. In addition, there is no indication that the model incorporates confidence intervals or uncertainty bounds around its key assumptions, such as source term variability, treatment system performance, or climate inputs. The absence of an uncertainty assessment prevents reviewers from understanding the full range of	Please refer to responses in number 5 and number 10 above.	This comment has been marked as "closed" on the basis that it is being addressed in other responses (numbers 5 and 10). However, Great Bear Resources' approach (comment and response table) of copying excerpts from the July 7, 2025, technical memorandum and providing partial responses does not address the underlying concern.	Comment is closed

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	possible outcomes and limits confidence in the model's robustness.			
C.12	The proponent should re-evaluate the ETP design to confirm whether the proposed MBBR has sufficient capacity and the necessary treatment steps to effectively remove ammonia, nitrite, and nitrate to levels protective of the receiving environment. If nitrate is expected in the effluent, a denitrification stage should be added to the treatment train.	The ETP has been designed to achieve effluent limits that meet water quality guidelines for the protection of aquatic life in the receiving environment, under all receiver flow conditions, inclusive of the 7Q20 low flow condition, as per MECP policy requirements. A denitrification stage is not required to meet applicable water quality guidelines for nitrogen species in the receiving environment. As noted in Great Bear's letter to ANA dated February 5, 2025, responding to ANA comments received on September 6, 2024, a comprehensive follow-up monitoring and adaptive management framework is in place. This framework specifically addresses nitrogen species and includes: • Regular monitoring of effluent and receiving water concentrations; • Defined trigger thresholds for key parameters; and • Contingency measures to be implemented if observed concentrations approach or exceed trigger values. This approach reflects standard practice and provides the necessary flexibility and responsiveness to manage potential variability in	Based on the Kinross Great Bear – Veolia Process memo, the influent water is expected to contain 30–50 mg N/L of ammonia, which would be biologically oxidized to nitrate through the MBBR's nitrification process. However, without a denitrification step, this would likely result in high nitrate concentration in the treated water. Since there are currently no effluent limits proposed for nitrate, it is unclear how the ETP, as designed, would ensure compliance with Water Quality Guidelines (WQG) or effluent limits protective of aquatic life. As noted in previous Source's responses (September 5, 2024), Source maintains that adaptive management is not a replacement for protective effluent criteria limits. Effluent criteria limits should reflect the reasonable ability of treatment to remove parameters from effluent as well as site-specific considerations related to bioaccumulation, human exposure, cumulative impacts, and other ecological risks, rather than relying on the assimilative capacity of the receiving water body. The proposed discharge limits are far higher than levels treatment technology can reasonably treat to. As such, this comment has not been addressed. These recommendations remain still outstanding. **Recommendation:** The proponent should re-evaluate the ETP design to confirm whether the proposed MBBR has sufficient capacity and the necessary treatment steps to effectively remove ammonia, nitrite, and nitrate to levels protective of the receiving environment. If nitrate is expected in the effluent, a denitrification stage should be added to the treatment train. **Recommendation:** The system should be modeled and validated under reasonable and conservative nitrogen loading scenarios to ensure that treated effluent meets all	The technical basis for approval of the ECA ISW is sufficient and has occurred as per the appropriate regulatory regime in Ontario; please see response to Comment C.1. Also, as per our previous responses, the proposed effluent limits are both appropriate and protective of the receiving environment. The assertion that the absence of a denitrification step compromises compliance with water quality guidelines is not accurate and overlooks several key facts: – Effluent criteria were developed using conservative assumptions, including maximum discharge volumes coinciding with 7Q20 low-flow conditions, in accordance with MECP Policy B-1-5. These criteria ensure that downstream water quality objectives for aquatic life are met—even under worst-case scenarios. – Nitrate and nitrite are not expected to pose a risk to the receiving environment under the proposed mitigation and management options and treatment configuration. There is a proposed effluent limit for ammonia, and trigger measures for adaptive management (including addition of treatment trains or holding water etc.) for nitrate, nitrite and ammonia. – Agree, adaptive management is not a substitute for effluent limits—but a complement to them. The AEX Program includes robust mitigation and management measures, active water treatment, extensive follow-up monitoring, contingency storage, and modular treatment flexibility to respond to any deviations from expected performance. This approach is consistent with MECP's risk-based permitting framework and represents industry best practice. – The proposed effluent limits reflect both the reasonable capabilities of the treatment system and site-specific environmental conditions, as developed

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
		nitrogen concentrations over time, without the need for additional treatment stages beyond what is currently proposed.	applicable discharge standards. In addition, the water quality model should be updated to reflect post-treatment concentrations of all nitrogen species, including nitrate, and assessed for compliance with downstream aquatic life guidelines. **Recommendation:** An effluent discharge limit should be established for nitrate to ensure treatment aligns with applicable provincial and federal water quality standards and to support the long-term effectiveness of the site's nitrogen management strategy.	by Hatch engineering. They are not technology-forcing, but rather grounded in what is achievable and protective, based on validated geochemical data, industry-standard treatment performance, extensive geochemical studies, and receiving water characteristics. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.13	Source remains concerned about the uncertainties and limitations in the current water quality model. It is also important to note that the proposed ECA conditions also include effluent discharge limits for sulphate which are being reviewed by methylation experts for Grassy Narrows. The proposed effluent limits leave a narrow compliance margin, and if site conditions change or the influent sulphate concentrations increase beyond current estimates, the project may not be able to meet the proposed compliance requirements without additional treatment.	Please refer to response number 5.	Great Bear Resources' approach (comment and response table) of copying excerpts from the July 7, 2025 technical memorandum and providing partial responses does not address the underlying concern. This comment is regarding Sulphate Treatment (Comment 14 in the Source's technical memorandum dated July 7, 2025). Response number 5 does not address the concerns outlined herein. The proposed ETP does not include a treatment stage for sulphate. According to email correspondence from Kinross dated June 5, 2025, in response to the MECP's Sulphate Management Information Request, the company evaluated options such as Reverse Osmosis (RO) for sulphate removal. Kinross concluded that a dedicated sulphate removal system was not warranted due to the company's predicted concentrations of sulphate in the influent water and the expense. Source remains concerned about the uncertainties and limitations in the current water quality model. It is also important to note that the proposed ECA conditions also include effluent discharge limits for sulphate which are being reviewed by methylation experts for Grassy Narrows. The proposed effluent limits leave a narrow compliance margin, and if site conditions change or the influent sulphate concentrations increase beyond current estimates, the project may not be able to meet the proposed compliance requirements without additional	The technical basis for approval of the ECA ISW is sufficient and has occurred as per the appropriate regulatory regime in Ontario; please see response to Comment C.1 and Comment C.12. All data collected to date show that sulphate levels are extremely low. The only known, potentially applicable, treatment technology to further reduce sulphate is Reverse Osmosis (RO). RO systems present significant operational challenges, particularly related to brine and waste management. Implementing a brine management system to address a risk that has not been demonstrated would introduce unnecessary environmental and operational burdens. Based on the feedwater quality to the AEX Effluent Treatment Plant (ETP), expected to contain low levels of sulphate, use of a sulphate removal system such as RO is not warranted during the AEX phase. Background concentrations of sulphate will be met in the Chukuni River with AEX effluent discharge as per MECP Policy B-1-5. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
			treatment. Given the inherent variability of site conditions during construction, exploration, and closure phases, sulphate management strategies and relevant treatment technology should be evaluated further to support compliance. **Information Request:** The information package received includes a folder titled, "9. June 6 -2025 – Sulphate management," but this folder appears to be empty. Please provide the sulphate management document for review. **Recommendation:** Relevant available sulfate treatment technologies should be assessed for feasibility, effectiveness, and operational considerations. **Recommendation:** A sulphate removal system should be assessed and included as a potential contingency measure to support compliance. A sulphate management plan should include a clear and measurable trigger mechanism, based on influent and effluent sulphate monitoring results, which would initiate protective actions. ANA and their reviewers must be given an opportunity to review and comment on the finalized report before it is used to support regulatory decisions.	
C.14	The current water balance and water quality model (WBWQM) reports are based on a few years of baseline data collected before site groundwork began and are presented as a preliminary prediction. However, it remains unclear how the water balance and water quality model will be reconciled and updated over time to reflect actual site-specific monitoring data once construction and exploration activities begin. The model should not be static throughout the life of the project as this increases	Please refer to response number 5.	The proponent's response indicates that the water balance and water quality model (WBWQM) would be updated every three years and compared against monitoring results. However, the submitted WQM memo (Advanced Exploration Program (AEX) Water Quality Estimate Update, Great Bear – Draft, February 1, 2024) is based on a steady state model. This modeling approach does not account for temporal variability or transient changes in water chemistry and hydrology. Each project phase (construction, active closure, passive closure, and post-closure) introduces distinct water quality risks and management needs. A static model cannot capture the dynamic responses of groundwater and surface water systems to dewatering, changes in site	We acknowledge the reviewer's continued concerns regarding the modeling approach and update frequency for the Water Balance and Water Quality Model (WBWQM). As previously stated, the current steady-state model reflects a conservative approach appropriate. The model will be updated every three years and compared against monitoring results to support adaptive management and ensure alignment with site conditions. It is important to note that evaluation of closure-related water quality risks and management strategies was completed as part of the Closure Plan review. The Closure Plan for the Great Bear Project has been filed and approved, and includes consideration of water

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	the risk that predicted outcomes will become misaligned with the reality on the ground as site conditions evolve. Annual comparison between modeled and observed data is essential for keeping water management strategies responsive and effective. It is recommended that the WBWQM be updated on an annual basis to reflect changes in climatic conditions, operational flows, and site water storage volumes. These regular annual updates enable operators to make informed adjustments to pond management, flow controls, and overall system performance. Ongoing monitoring of pond levels and inflow/outflow dynamics not only supports operational efficiency but also enhances the early detection of deviations that could signal system vulnerabilities.		operations, climate variability, or evolving geochemical conditions. Without transient modeling, it is unclear how the proponent intends to reconcile monitoring results with predictive outputs or use those comparisons to adaptively manage water quality. The current approach risks misalignment between predicted and actual outcomes, potentially leading to ineffective or delayed mitigation measures. In addition, the proposed three-year update interval is not sufficient for a five-year permit term. A revision at the three-year mark occurs 60% of the way through the project, meaning that if the model is inaccurate, the proponent could operate under false or outdated predictions for the majority of the permit duration. At that point, the project may also be in a different phase (e.g., shifting from construction to operation, or into closure), such that monitoring data used for recalibration would not reflect the conditions of the upcoming two years. With no further model updates scheduled within the 5-year term, there is a significant risk that the model will not represent actual site conditions during later phases of work. **Recommendation:** The proponent should develop a transient water quality model capable of simulating time-varying conditions. This would allow for meaningful comparison to monitoring data. **Recommendation:** Updates should occur at minimum at each project phase change, to ensure monitoring data remain representative of actual conditions and predictive outputs remain reliable. This is necessary to ensure meaningful comparison with monitoring data, timely detection of deviations, and effective adaptive management.	quality conditions and mitigation measures across all closure phases While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.15	Surface Water Monitoring Plan – Recommendations **Recommendation:** The final Industrial Sewage Works ECA should	The final monitoring plans will be referenced in the conditions of approval and will therefore form part of the formal requirements of the final authorization. This will include the	The Proponent's response partially addressed the July 7, 2025, comment. The original comment also requested clarification on the locations of the surface water quality monitoring locations under the SWMP. Source assumed that the monitoring locations in the SWMP were the same	Coordinates, listed tables, and maps of proposed monitoring locations are provided in the monitoring plans submitted to support both the PTTW and ECA ISW applications, including the Surface Water Monitoring Plan.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	include a complete list of surface and groundwater monitoring stations, including the locations listed in Table 1 of the AEX Surface Water Quality Workplan. Each station should also be associated with applicable regulatory thresholds (e.g., effluent limits, trigger criteria).	required surface water and groundwater monitoring locations, and corresponding UTMs.	as those listed in Table 1 of the AEX Surface Water Quality Workplan. This comment remains open pending review of the final draft ECA and attached SWMP. **Clarification:** Without coordinates or a spatial figure in the SWMP, it is difficult to assess whether the proposed water quality monitoring stations are appropriately located. Source requests confirmation from MECP/Kinross that the stations included in Table 1 of the 2023 Surface Water Quality Workplan correspond to those listed in the SWMP. **Recommendation:** Please revise the SWMP to include coordinates for the surface water quality monitoring stations. ANA and its technical reviewers need to review and provide comments prior to ECA decisions.	
C.16	Surface Water Monitoring Plan – Recommendations **Recommendation:** Trigger response plans are often broken down into several action levels, which escalate in severity from low to high risk. Table 4 provides an example structure for the Trigger Criteria that follows this standard approach. Source recommends that the MECP consider this approach for incorporation into the proposed ECA for review by ANA and others.	The proposed trigger response framework was developed in coordination with the MECP and is consistent with ECA ISW policy framework and associated guidance documents. There are no proposed changes to the wording of Trigger Criteria in this regard.	Source notes that the full comment, including Table 4, was not included in the Proponent's response to July 7, 2025, comments. Therefore, the response is missing key context and may be incomplete. The suggestions provided in Table 4 of Source's original memorandum expand upon the original proposed trigger response framework. Incorporating these recommendations would not undermine the guidance of the ECA ISW policy framework and associated guidance documents. It is important to emphasize that development of the Trigger Response Plan in coordination with MECP does not demonstrate, on its own, that the plan is sufficiently protective. Regulatory acceptance establishes a minimum compliance baseline, but it does not guarantee that the framework adequately addresses site-specific risks, ecological sensitivities, or cumulative effects. The fact that MECP was involved in its development should not preclude further improvement. Source offers these recommendations with the goal of ensuring that the TRP is as robust and protective as	see response to Comment C.1. While we acknowledge the recommendations provided, we remain confident in the structure and content of the Trigger Response Plan (TRP) is consistent with ECA ISW policy and framework and associated guidance documents. As stated in earlier responses there are no proposed changes to trigger criteria at this time by GBR. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
			possible, particularly given that adaptive management is central to the Proponent's overall mitigation strategy. A weak or incomplete TRP could undermine the effectiveness of adaptive management and increase the risk of delayed or insufficient responses to environmental stressors. **Recommendation:** Trigger response plans are often broken down into several action levels, which escalate in severity from low to high risk. Table 4 provides an example structure for the Trigger Criteria that follows this standard approach. Source recommends that GBR considers this approach for incorporation into the proposed ECA for review by ANA and others.	
C.17	Surface Water Monitoring Plan – Recommendations **Recommendation:** Trigger Criteria b should be revised to clarify which monitoring stations it applies to. Does it only apply at the end of the effluent mixing zone? Or at all impact monitoring stations?	Trigger criteria b applies to all off-site monitored surface water quality locations.	Thank you for the clarification. This comment remains open until the wording for Trigger Criteria b has been revised to clarify which monitoring stations it applies to. **Recommendation:** Trigger Criteria b should be revised to clarify that it applies to off-site surface water quality monitoring stations.	Trigger criteria identified in the Surface Water Monitoring Program for off-site monitoring locations apply to all off-site surface water monitoring locations, including Chukuni River (receiving environment) and other monitored watercourses (e.g. Dixie Creek).
C.18	Surface Water Monitoring Plan – Recommendations **Recommendation:** Trigger Criteria b references either the WQG PAL or "baseline equivalents". It is unclear which parameters will be compared against the WQG PAL, and which will be compared against "baseline equivalents".	Baseline equivalents are where baseline conditions are greater than WQG PAL, which will be documented in annual compliance reporting. There are no proposed changes to the wording of Trigger Criteria b in this regard.	The original comment has not been addressed. Wouldn't baseline period be over once construction on the Project begins? If so, the baseline conditions will not change over time with each annual report. At this time, the Proponent should have a sense of what parameters are naturally elevate above baseline concentrations. In addition, Source requested that the Trigger b concentration thresholds be defined for each parameter in the ECA. This recommendation was not addressed in the Proponent's response. **Information request:** Please confirm which parameters have baseline concentrations greater than WQG PAL, based on data gathered to date. **Recommendation:** The Trigger b concentration thresholds should be defined for each parameter in the ECA. This should include which thresholds are based on	The technical basis for approval of the ECA ISW is sufficient and will occur as per the appropriate regulatory regime in Ontario; please see response to Comment C.1 Baseline equivalents means concentration observed during baseline monitoring program, which yes, ends with the commencement of AEX Program discharges. This is to refer to existing concentrations greater than WQG PAL in baseline conditions, which are not an effect of the AEX Program (for example, arsenic in the Chukuni River). While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
			WQG PAL, and which are based on baseline concentrations.	
C.19	Surface Water Monitoring Plan – Recommendations: The intent of Trigger Criteria c should be clarified. Revised trigger response plan should be circulated to ANA and other reviewers for review and comment prior to the issuance of any ECA decision.	More plainly, Trigger Criterion C means that if concentrations of parameters with Water Quality Guidelines for the Protection of Aquatic Life (WQG PAL) are consistently increasing in the receiving environment, an "investigation of cause" will be triggered—even if there is not yet a clear long-term trend indicating that the guideline will be exceeded. There are no proposed changes to the wording of Trigger Criteria c in this regard.	Thank you for the clarification. **Recommendation:** Source requests that Trigger c be updated to include the language in the Proponent's response.	Agree, the language will be included in the final ECA ISW approval, as requested.
C.20	**Recommendation:** To ensure a proactive approach, trigger a should be revised to detect concerning trends earlier. A lower threshold (such as 80%) is recommended to initiate root cause analysis and early stage mitigation. These revised trigger levels should be consulted on, subjected to technical review, and incorporated into the proposed ECA.	The current trigger structure, including Trigger A, was developed in alignment with the MECP policy and reflects a risk-based framework that is both technically defensible and appropriately protective. Trigger A is designed to detect exceedance risk based on modelled predictions and observed data and is supported by additional triggers that respond to increasing trends and parameter variability. No single trigger is intended to operate in isolation. Rather, the full suite of triggers works together to provide early warning, guide investigation, and implement mitigation if needed. This integrated approach, combined with regular monitoring and adaptive management, ensures that potential	The response to this comment is confusing. Source's original comment requested a lower threshold (e.g., 80%) for Trigger a. At this threshold, the Proponent would initiate a root cause analysis and identify early-stage mitigations. In response, the Proponent states that "A revision to Trigger A is not warranted, no changes to the trigger criteria have been made in this regard." However, the comment later commits to the 80% trigger threshold. This comment remains open pending review of a revised TRP **Recommendation:** Please revise the trigger response framework to incorporate the lower threshold (i.e., 80%) committed to in the round 1 response. These revised trigger levels should be consulted on, subjected to technical review, and incorporated into the proposed ECA.	The technical basis for approval of the ECA ISW is sufficient and has occurred as per the appropriate regulatory regime in Ontario; please see response to Comment C.1. To clarify, the trigger criteria in the surface water monitoring program document are currently as follows: – Three consecutive final effluent sampling results exceed 90% of the monthly average effluent limit for any parameter, including sulphate, with an associated increasing trend, based on application of the Mann – Kendall non-parametric test. – There is an observed statistical trend towards increasing parameter concentrations in the receiving environment, including sulphate, mercury and methylmercury, based on application of the Mann – Kendall non-parametric test, such that there is a likelihood of applicable Water Quality Guidelines for the Protection of Aquatic Life (WQG PAL), or baseline equivalents, being exceeded in the

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
		risks are identified and addressed in a timely and effective manner. A revision to Trigger A is not warranted, no changes to the trigger criteria have been made in this regard. GBR will commit to the lower 80% trigger threshold.		receiving environment (beyond the mixing zone) should the trend continue. – Additionally, in the case of the British Columbia Protection of Aquatic Life guideline for total mercury, although the BC guideline is based on the average concentration of total mercury in water as measured over a 30-day period (based on five weekly samples); an adaptive management approach will be implemented where individual monthly results show exceedance of the guideline. In which case mercury and methylmercury sampling is to occur weekly. Should exceedances still be observed, BC's complete approach to monitoring will be followed.
C.21	**Recommendation:** Trigger Criteria b should be rewritten to ensure a proactive approach to protecting receiving environment water quality. Please see Table 4 for recommendations. These revisions should be adopted as enforceable conditions of the AEX ECA.	Revisions to Trigger Criterion B are not necessary. The existing language is consistent with MECP policy and supports a proactive, risk-based approach to protecting receiving water quality. No changes are proposed.	Please see Source's Evaluation of the response to Comment 16.	The technical basis for approval of the ECA ISW is sufficient and has occurred as per the appropriate regulatory regime in Ontario; please see response to Comment C.1
C.22	**Recommendation:** The proponent should reevaluate the ETP design to confirm whether the proposed MBBR has sufficient capacity and the necessary treatment steps to effectively remove ammonia, nitrite, and nitrate to levels protective of the receiving environment. If nitrate is expected in the effluent, a denitrification stage should be added to the treatment train.	A response was provided to ANA on February 5, 2025, addressing the concerns raised about nitrogen species in ANA's letter dated September 6, 2024. Please see response to comment 12.	Comment Closed. As suggested, Source's evaluation of response is provided in Comment 12.	
C.23	**Recommendation:** Relevant available sulfate treatment technologies should be assessed for feasibility, effectiveness, and operational considerations.	Please see response to comment 12.	The Proponent already copied and pasted this Source's comment in Comment 13. It appears redundant. Please see Comment 13 for Source's evaluation of response.	Acknowledged. Please see response to comment C. 13.

Comment ID	July 7, 2025, Source Comments & Rationale	July 10, 2025, Great Bear Resource Response	Source Evaluation of Response	Great Bear Resources Response
	Recommendation: A sulphate removal system should be assessed and included as a potential contingency measure to support compliance. A sulphate management plan should include a clear and measurable trigger mechanism, based on influent and effluent sulphate monitoring results, which would initiate protective actions. ANA and their reviewers must be given an opportunity to review and comment on the finalized report before it is used to support regulatory decisions.

Subject: Ministry of Environment, Conservation and Parks ("MECP") – Great Bear Resources Ltd. ("Great Bear") – Advanced Exploration (AEX) Program – Permit to Take Water ("PTTW") – Environmental Compliance Approval ("ECA") – ERO No. 025-0579

This letter accompanies our responses to comments sent on behalf of Asubpeeschoseewagong Anishinabek ("**ANA**") on the Great Bear Advanced Exploration (**AEX**) Program, which were submitted in the following documents:

a. Letter dated 19 August 2025 from MDAG;

b. Letter dated 24 August, 2025 from Brian Branfireun;

c. Technical Memorandum "Source Evaluation of Great Bear Resources' Responses to Summary Comments on AEX ECA" dated 30 August 2025; and

d. Technical Memorandum "Source Evaluation of Great Bear Resources' Response to Summary Comments on AEX PTTW" dated 13 September 2025.

These documents are entirely repetitive of comments to which Great Bear has already responded. As you will see, Great Bear refers MECP to its previous responses.

1. Indigenous Community interest in the AEX Activities and the Application

The Province included three communities on the consultation list for permits related to the Great Bear project: Lac Seul First Nation ("**LSFN**"), Waubuskang First Nation ("**WFN**") and ANA.

LSFN and WFN have filed letters of support for Great Bear's AEX permits, including the PTTW and ECA, and are further engaged in negotiations with Great Bear for an agreement that would establish the basis upon which the Project would proceed with their support. Conversely, ANA has been clear in its engagement with Great Bear, MINES, MECP and IAAC that it will oppose the Project regardless of the Project information, risk management measures, or Project accommodations that Great Bear offers.[1]

2. The repetitive nature of the comments

ANA's expert letters and technical memoranda raise no novel issues or concerns. Instead, they state that the responses that Great Bear has provided do not satisfy ANA. Providing the specific data and performing

[1] See page 3 of the ANA letter to IAAC and MINES on 6 March 2024.

the specific tests that ANA demands is not a reasonable approach and is not based on any credible scientific or legal foundation.

Great Bear has engaged with ANA extensively since 2022 including engagement with the many rounds of comments provided by ANA's experts.[2] These comments have become repetitive and, as a result, Great Bear has been obliged by MECP to respond comments that it has already responded to, in some cases many times. Great Bear already responded to all the issues raised by ANA in the latest round of comments so it is unproductive to provide future Great Bear response comments. The permit review record would be extended but not improved.

MECP should end this open-ended loop of repetitive comments. This approach is unnecessary and procedurally unfair to Great Bear. It also allows ANA to hijack the permitting process causing endless delay. Where there is a disagreement between ANA and Great Bear on the data provided or the testing and modeling performed, MECP must decide the issue based on the merit of the information on the record. That is MECP's role as decision-maker,

3. The Duty to Consult has been met

As stated in Great Bear's letter dated 15 August 2025, the Crown has met the Duty to Consult by the standards set out in the Ontario policy and applicable case law.[3] Moreover, MINES, MECP and Great Bear have engaged with ANA on the "higher/deeper" end of the "Consultation Spectrum".[4] ANA has had a reasonable opportunity to express their interests and to comment on all aspects of the requested permits. MECP must now make a decision on those permits.

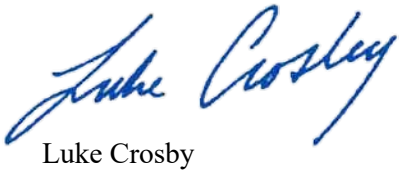
4. Concluding Comments

Great Bear has provided more than adequate information to support the issuance of the requested permits. This permit review has far exceeded all comparable permit reviews of this nature in time and volume of information requested. Accordingly, Great Bear does not intend to respond to future information requests related to the PTTW and ECA. MECP must conclude this review and issue its decision.

Thank you for your prompt attention to this urgent issue.

Sincerely,

GREAT BEAR RESOURCES LTD.



Luke Crosby

Great Bear Resources Ltd.'s (GBR) Response to September 13th, 2025 Letters from Source Environmental.

Source Evaluation of Great Bear Resources' Responses to Summary Comments on AEX ECA

Table 2: GBR Response to September 13th, 2025 Letter.

#	July 23, 2025, Source Comments & Rational	July 24th, 2025, Great Bear Resource Response	Sept 13th, 2025, Source Evaluation Response	GBR Response
C.1	*The proponent should submit an updated Water Quality Model (WQM) report that incorporates and addresses the outstanding technical issues raised in Source's memorandum titled "Review of Great Bear Advanced Exploration Program ECA ISW Application – Follow-Up Comments on Latest Technical Materials" dated July 7, 2025. ANA and their reviewers must be given an opportunity to review and comment on the updated report before it is used to support regulatory decisions.*	GBR has previously addressed this comment in its June 18, 2025, submission titled 'Great Bear Resources Ltd.'s Response to Source Environmental Associates Inc. Technical Memorandum – Review of Great Bear Advanced Exploration Program – Permit to Take Water Application for Dewatering (Updated), dated April 11, 20	Source previously reviewed Great Bear's June 18, 2025, response, including Attachment 1 (Water Quality Model memo). The Attachment 1 was considered a latest WQM memo by the Proponent. Source's July 7, 2025, memorandum, titled "Review of Great Bear Advanced Exploration Program ECA ISW Application – Follow-Up Comments on Latest Technical Materials" highlighted concerns that remains following the review of the latest WQM memo. Almost all comments concerning the WQM remain outstanding, as provided in the Source's follow-up evaluation of Kinross' response on the ECA, dated August 8, 2025. For context and tracking purposes with respect to the review of PTTW, the following background information was included in the July 7, 2025, Source's PTTW memo (C.1): The proponent's response to the previous review comment on the absence of a water quality model asserts that the PTTW Application focuses strictly on water quantity, and that matters related to water quality are instead addressed under the Environmental Compliance Approval (ECA) for Industrial Sewage Works (ISW). However, this division between water quantity and quality is problematic from a technical perspective. The PTTW Application proposes dewatering activities that will generate contact water requiring management and discharge to the environment. The projected water takings are based on predicted inflows to the underground workings and surface contact areas, which depend on both groundwater and surface water contributions. Moreover, changes to groundwater flow patterns, heads, and volumes can impact water quality throughout the site, including in areas that may not contribute flow directly to the underground workings. Altering groundwater gradients can mobilize contaminants or induce mixing between geochemically distinct water sources. These water quality effects may not be captured within the scope of the ECA, particularly if the affected groundwater is not collected and treated. As such, understanding the quality of these inflows is essential for evaluating the potential risks to receiving environments and determining appropriate mitigation strategies. Separating water quantity and water quality assessments into entirely distinct regulatory silos is therefore technically unsound. The groundwater system does not distinguish between these two elements. Contaminant loads and water volumes are inherently linked. For the purpose of environmental protection, it is critical that both aspects be evaluated together to identify how inflow water volumes and chemistry may interact and evolve, particularly in the early phases of dewatering and during periods of operational change.	We acknowledge the concerns raised in the July 7 and August 8, 2025 memoranda regarding the integration of water quantity and quality assessments. To clarify, the Water Quality Model (WQM) memo referenced in your July 7, 2025 comments was previously shared with ANA as Attachment 1 to our June 18, 2025 response. This memo represents the most current version of the WQM and was developed to support the Environmental Compliance Approval (ECA) for Industrial Sewage Works (ISW). We understand that some concerns remain regarding the scope and integration of water quality considerations within the Permit to Take Water (PTTW) application. While the PTTW application focuses on water quantity, we recognize the interconnected nature of groundwater flow and water quality. Accordingly, the Hydrogeological Monitoring Plan includes water quality triggers designed to identify and respond to potential changes in groundwater chemistry that may arise from dewatering activities. These triggers are intended to ensure that any water quality impacts are detected and addressed in a timely manner, supporting the overarching goal of environmental protection. We appreciate the importance of a holistic approach and remain committed to ensuring that both water quantity and quality considerations are appropriately addressed through the coordinated implementation of the PTTW and ECA frameworks.

#	July 23, 2025, Source Comments & Rational	July 24th, 2025, Great Bear Resource Response	Sept 13th, 2025, Source Evaluation Response	GBR Response
C.2	*The proponent should provide further detail on the implementation status of the grouting program, including the number and location of boreholes treated to date, plans and schedules for sealing remaining boreholes (both inside and outside the mine footprint), methods for verifying sealing effectiveness, and confirmation of how boreholes (both sealed and unsealed) are represented in the groundwater model.* *Further, the proponent should assess and disclose the potential hydrologic effects of both historical and planned exploration holes on model parameters, groundwater flow patterns, and water balance predictions. If necessary, sensitivity analyses should be conducted to evaluate the uncertainty introduced by these features. This information needs to be provided to validate that potential high-permeability pathways created by historical drilling activities have been adequately mitigated and incorporated into the site's hydrogeological model and water management strategy.*	GBR has previously addressed the grouting comment in its June 18, 2025, submission titled "Great Bear Resources Ltd.'s Response to Source Environmental Associates Inc. Technical Memorandum – Review of Great Bear Advanced Exploration Program – Permit to Take Water Application for Dewatering (Updated), dated April 11, 2025" and 'Great Bear Resources Ltd.'s (GBR) Response to Minesite Drainage Assessment Group Document – Great Bear Mining Project – Comments on the New 2025 PTTW Application, dated April 11, 2025'. The impact of the open exploration holes on the model results should be considered in relation to the area of their influence, their size, the size of the model and site stratigraphy. Most exploration holes are very small with a radius of less than 1", while the groundwater model domain is very large, covering 180 km2, (of which only a very small portion is influenced by open exploration holes). The area of influence of open exploration drillholes under drilling and testing conditions was 30m, it would be far less under typical, undisturbed gradient conditions. Furthermore, the open exploration holes are completed in bedrock, are capped to prevent artesian flow, and largely located in areas with thick clay cover, such that they have little influence of surface water flows. Almost none of the 109 points used for model calibration are located close to open exploration drillholes, and as such the drillholes will not have had a significant impact on the model calibration. They could have a significant impact under conditions of high gradients, such as near a dewatered underground facility, however, given they will be grouted in proximity to the ramp, the condition is not applicable and not simulated.	GBR acknowledged that open boreholes could have a significant impact under conditions of high gradients, such as near a dewatered underground facility. In its June 17, 2025 response, GBR indicated that it had initiated a grouting program in February 2024 to seal exploration boreholes, and that the program was ongoing as of that date. While GBR states that industry-standard grouting techniques are being used, it also concedes that any ungrouted boreholes intersected by underground workings could result in increased groundwater inflows until grouting is completed. Given that the proponent has drilled more than 2,500 exploration holes, it remains unclear which boreholes have been successfully grouted and which remain open. This represents a significant source of uncertainty for the hydrogeologic model and associated water management predictions. At the time of writing, no comprehensive accounting has been provided to demonstrate the status of borehole sealing across the project area. To reduce this uncertainty, the Proponent should provide a map and inventory that clearly identifies the location and grouting status (sealed versus unsealed) of all boreholes within the project boundary. Any ungrouted boreholes within the zone of influence described in the hydrogeological analysis of the PTTW Application have the potential to act as preferential flow pathways, thereby impacting model calibration, groundwater flow predictions, and ultimately the water quality prediction. Accordingly, the grouting program should also be clearly documented, summarized, and tracked for ANA's review prior to the regulatory decision on this PTTW Application. This document should also be used to reconcile with the water balance and water quality predictions of mine inflows. This comment remains unaddressed.	We acknowledge the reviewer's continued concern regarding the grouting of exploration boreholes and its potential influence on groundwater flow predictions. As previously communicated, Great Bear Resources Ltd. (GBR) addressed this comment in its June 18, 2025 submission titled "Great Bear Resources Ltd.'s Response to Source Environmental Associates Inc. Technical Memorandum – Review of Great Bear Advanced Exploration Program – Permit to Take Water Application for Dewatering (Updated), dated April 11, 2025" and in the response to the Minesite Drainage Assessment Group Document dated April 11, 2025. The potential impact of open exploration holes on the groundwater model has been carefully evaluated in relation to their physical characteristics, spatial distribution, and the overall model domain. Most boreholes are small in diameter, completed in bedrock, capped to prevent artesian flow, and located in areas with thick clay cover, limiting their influence on surface water and groundwater dynamics. Their area of influence under undisturbed gradient conditions is minimal, and they are not proximate to the majority of model calibration points. We also note that GBR is bound by the conditions and limitations of the Permit to Take Water (PTTW), which governs water takings and associated management practices. These regulatory constraints ensure that groundwater inflows and related risks are managed in accordance with provincial requirements. We remain confident that the work aligns with the permit application requirements for a Permit to Take Water (PTTW) and an Environmental Compliance Approval (ECA) in the province of Ontario. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.3	*"Table 1-1 of the PTTW application (May 2025) lists the amount of water requested from each individual source, with a stated total of 2,555 m3/day. However, summing the individual daily water taking values results in a total of approximately 2,865 m3/day (or 1.05 Mm3/year) during the construction phase and 2,805 m3/day after the first year."*	Table 1-1 was copied from the groundwater modelling report that does not include 250 m3/day taken from Dixie Creek, which is a surface water source.	Please revise the Table to reflect a correct total amount of requested water taking.	We remain confident that the work aligns with the permit application requirements for a Permit to Take Water (PTTW) and an Environmental Compliance Approval (ECA) in the province of Ontario. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.4	*"While the [GBR] response recognizes uncertainty in aquifer yield, it ultimately downplays the predicted 55% baseflow reduction without presenting concrete mitigation measures or a reasonable ecological justification. Several issues remain*	Because of the small quantity of groundwater involved, the hydrologic impact of the flow reduction in terms of hydrologic conditions, even if the percent change in the model simulated groundwater component, appears large. Unnamed Watercourse is a sizeable watercourse (9.4 km2), such that the equivalent water contribution of	While the proponent frames the predicted 55% reduction in baseflow as a small absolute volume and a contingency-only concern, this response does not address the fundamental operational and ecological risks identified in Source's original comment. Source requests for: • Trigger Criteria for Supplementation – In Comment C.5 below, GBR indicates that	We acknowledge the reviewer's continued concerns regarding the hydrologic impact to the Unnamed Watercourse and the proposed supplementation wells. These issues have been addressed in previous submissions, including our assessment of groundwater contributions, seasonal flow variability, and the

#	July 23, 2025, Source Comments & Rational	July 24th, 2025, Great Bear Resource Response	Sept 13th, 2025, Source Evaluation Response	GBR Response
	unresolved: *• Ecological Risk Mischaracterized: The assertion that Unnamed Watercourse 3 is often dry in winter does not address the potential impact of sustained flow reductions during other seasonal periods (e.g., spring and summer). A modeled 55% reduction in baseflow represents a substantial change in hydrologic regime, with potential consequences for aquatic habitat that extends beyond natural seasonal variability.* *• Lack of Proven Yield for Supplementation Wells: The response relies on bedrock permeability values from the groundwater model, which were not intended for production well design. No aquifer pump testing has been conducted to confirm that the wells can meet the required supplementation volumes.* *• Reliance on Undemonstrated Flexibility: The proponent's reliance on a "sufficiently flexible permit" to drill additional wells as needed transfers key risk management actions to a future stage, without assurance of feasibility of success. There is no backup plan for supplementation failure beyond proposing additional wells, despite the acknowledged low yield of the receiving aquifer. This reactive approach introduces the risk of prolonged periods during which supplementation is insufficient to protect the watercourse. A lag in expanding well capacity could lead to flow deficits during critical ecological windows. A proactive and tested contingency plan is needed to ensure timely and reliable delivery of supplemental flow.* *Potential Ecological Effects of Groundwater Supplementation: The use of groundwater to replace a larger portion of surface water flow (up to 55%) raises concerns about compatibility with the existing aquatic ecosystem. Groundwater may differ from surface water both in physical and chemical parameters. This potential has not been evaluated."*	groundwater to the watercourse decreases to as low as 0.1mm/year, which for context, is much smaller than the evaporation rate. This is a large part of the reason that there are periods of no flow or very little flow (<100 m3/day) are also observed during the summer and early fall conditions as well as the winter. This watercourse is a runoff dominated watercourse, and it is these factors that dominate the ecological characteristics of the feature. It is proposed to evaluate the potential flow reductions in relation to a reference watercourse, to help assess the impacts of seasonal weather variation, and largely eliminates the needs to predict unknown future climatic conditions. The proposal to use the supplementation wells should be viewed as a contingency. The 55% simulated loss is derived from a model being used to assess potential changes. Actual changes are likely to be much less and could fail to trigger the need for supplementation. The slow development of the ramp, over 5 years, also means that the drawdown cone can be assessed with time, and the need or supplementation re-assessed. The wells do not have to be available immediately. In terms of differing quality, the objective is to replace the loss of groundwater contributions from the till and shallow bedrock with water drawn from these horizons and hence providing an approximate like for like replacement.	the threshold for assessing flow reduction for this project based on local conditions is set at a 20% flow reduction relative to a reference watercourse. The PTTW must clearly define quantitative thresholds and method for initiating supplementation. • Timing of Supplementation Infrastructure – Supplementation wells must be installed, tested for sustainable yield, and proven operational prior to any construction activities that could reduce flows in Unnamed Watercourse 3. The proponent's reliance on "progressive development" and post-impact reassessment creates a risk of extended low-flow conditions before mitigation can be implemented. • Confirmation of Groundwater Quality – Once supplementation wells are installed, groundwater quality should be tested and compared against surface water at the receiving environment for assessing adequacy of the supplementation. • Contingency for Well Failure or Insufficient Yield – The plan must include specific contingencies for scenarios where wells do not meet target volumes or fail mechanically, ensuring that supplementation commitments can be met without delay during critical flow periods. These measures are necessary to ensure that supplementation is timely, effective, and capable of protecting ecological flow needs. Without them, the PTTW would permit a high risk of delayed or ineffective mitigation, leading to potentially significant and avoidable ecological impacts.	contingency nature of the supplementation strategy. As stated, the watercourse is runoff-dominated, and the modeled groundwater reduction,while expressed as a percentage, is minimal in absolute terms and unlikely to materially affect ecological conditions. The supplementation wells are proposed as a precautionary measure, with deployment contingent on observed conditions over time. We remain confident that the work aligns with the permit application requirements for a Permit to Take Water (PTTW) and an Environmental Compliance Approval (ECA) in the province of Ontario. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.5	*The proponent should conduct aquifer pump testing to confirm the sustainable yield and operational feasibility of the proposed supplementation wells. They should also evaluate the ecological flow needs of Unnamed Watercourse 3 and justify the target supplementation volume relative to accepted environmental flow thresholds. Environmental flow guidance often recommends preserving 90% or more of natural flow to protect aquatic habitat (e.g., British Columbia Environmental flow needs policy), and this should be used as a benchmark in assessing the adequacy of mitigation and management strategy. A detailed and proactive contingency plan should be provided to address the risk of insufficient flow during well development or failure. Finally, the proponent should assess the*	Pumping tests to evaluate the yield will be completed once the wells are established. Note that the threshold for assessing flow reduction for this project based on local conditions is set at a 20% flow reduction relative to a reference watercourse.	The proponent has indicated that aquifer pumping tests to evaluate the yield of supplementation wells will be completed only after wells are established, and that the threshold for assessing flow reduction will be based on a 20% reduction relative to a "reference watercourse." However, it appears that the proponent has not identified which reference watercourse will be used, nor provided the criteria for its selection. Without a defined reference system and baseline dataset, the comment remains unaddressed. Prior to any dewatering, the Proponent should: • Identify the reference watercourse(s) and selection criteria. • If not already available, collect several years of baseline flow data (high, medium, and low flow years). • Justify the 20% threshold against accepted environmental flow standards A permit condition should require completion and submission of a reference watercourse study, including baseline monitoring results and ecological flow analysis,	We disagree pumping tests to evaluate the yield are required prior to establishing the wells. We remain confident that the work aligns with the permit application requirements for a Permit to Take Water (PTTW) and an Environmental Compliance Approval (ECA) in the province of Ontario. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

#	July 23, 2025, Source Comments & Rational	July 24th, 2025, Great Bear Resource Response	Sept 13th, 2025, Source Evaluation Response	GBR Response
	potential ecological implications of replacing surface flow with groundwater. This information should be submitted to ANA and its technical reviewers for consideration prior to any decision on the PTTW application.		before work begins.	
C.6	*The proponent should conduct a sensitivity analysis on groundwater recharge rates under observed and plausible near-term drought and climate change scenarios, including multi-year precipitation deficits and higher evapotranspiration rates.*	This is assessed by comparing the water taking impacts, developed under typical, annual average conditions to very low flow conditions, which is conservative, as this considers stream flows under dry conditions to mine dewatering under wetter conditions. Using this conservative approach, the predicted flow reductions in Dixie Creek are below the threshold. Keep in mind that for operations, the flow reductions will be compared to a reference watershed, which will be experiencing the same seasonal conditions as Unnamed Watercourse 3. This eliminates the need to rely of highly theoretical calculations about possible future climate conditions.	GBR's response frames its approach as "conservative," comparing water taking impacts under typical annual conditions to low flow conditions, and asserts that this eliminates the need to evaluate future drought or climate change scenarios. However, reliance on a single "conservative" assumption does not address the underlying concern: if the model inputs carry large uncertainties, errors in those inputs may be compounded, and the predictions of flow reductions may not be protective. A sensitivity analysis is still needed to be conducted. This analysis should quantify the range of error in key parameters (e.g., recharge rates, aquifer storage, hydraulic conductivity) and test how these uncertainties influence predictions of flow reductions under both normal and stressed hydrologic conditions. Without such analysis, it cannot be demonstrated that the PTTW application adequately accounts for uncertainty or that the risk of underestimating flow reductions in Dixie Creek watershed is acceptably low. In addition, please refer to the comment C.5 for discussion on the reference watershed.	We acknowledge the reviewer's continued recommendation for a sensitivity analysis. As previously communicated, GBR has assessed water taking impacts by comparing typical annual conditions to very low flow scenarios which is a conservative approach that evaluates stream flows under dry conditions against mine dewatering during wetter periods. Predicted flow reductions in Dixie Creek remain below threshold values. For operations, flow reductions will be compared to a reference watershed experiencing the same seasonal conditions, eliminating the need for speculative modeling of future climate scenarios. We do not consider a sensitivity analysis necessary and maintain that our approach is protective and consistent with the requirements of the Permit to Take Water (PTTW). This comment has been addressed. We remain confident that the work aligns with the permit application requirements for a Permit to Take Water (PTTW) and an Environmental Compliance Approval (ECA) in the province of Ontario. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.
C.7	*The proponent should clarify the site-specific thresholds or indicators that would guide water taking decisions under low flow conditions. This should include operational protocols for modifying or reducing water takings in response to observed stress in the receiving environment. Providing this clarity would improve alignment with MECP's sustainable water use objectives.*	This has previously been assessed. Inflow into the underground is controlled by gradients and not by pumping. Adjustments in pumping from the underground only result in a change of water accumulating in the underground but do not measurably reduce flow reductions in creeks.	Comment closed.	
C.8	*The proponent should provide the transient model and associated outputs for review, including:* *• Drawdown and flow hydrographs over time* *• Simulated heads at key monitoring points and surface water features* *• Sensitivity analysis on recharge, pumping schedules, and aquifer storage* *• Calibration data, model input/output files, and documentation of model* *• Error analysis and confidence intervals for all inputs and outputs* *Given the coarseness of the model and the known*	GBR has previously addressed this comment in its June 18, 2025, submission titled 'Great Bear Resources Ltd.'s (GBR) Response to Minesite Drainage Assessment Group Document – Great Bear Mining Project – Comments on the New 2025 PTTW Application, dated April 11, 2025'. The steady state approach is accepted by groundwater professionals worldwide and is not a limitation. Additional transient work would result in smaller, but less conservative predicted changes in stream flow. However, given that, with the existing conservative approach, stream flow impacts are less than 20% of flows in Dixie Creek, there is no benefit in terms of mitigation measures to undertaking further transient modelling. Furthermore, the uncertainty introduced with the	The proponent continues to assert that steady-state modeling is "conservative" and sufficient for impact assessment. However, this claim does not address the primary concern raised in our original comment, that steady-state outputs cannot capture the timing, rate, and seasonal variability of groundwater responses to dewatering, which are critical for effective adaptive management. Uncertainty exists in both steady-state and transient models, and in modern groundwater modeling practice, transient calibration against monitoring data is a standard, accepted approach for increasing predictive confidence over time. In fact, the proponent's stated plan to "compare against a reference watercourse" would be more effective if supported by a transient framework capable of simulating seasonal variability and operational changes. Our position remains that the proponent should provide the transient modeling outputs referenced in their response, along with documentation of model assumptions, calibration, and sensitivity testing. This is necessary to: 1. Evaluate potential early-stage and seasonal impacts on surface water features.	We disagree with the reviewer's position that transient modelling should be undertaken, for reasons that have been clearly outlined in previous responses. We remain confident that the work aligns with the permit application requirements for a Permit to Take Water (PTTW) and an Environmental Compliance Approval (ECA) in the province of Ontario. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

#	July 23, 2025, Source Comments & Rational	July 24th, 2025, Great Bear Resource Response	Sept 13th, 2025, Source Evaluation Response	GBR Response
	limitations of steady-state assumptions, this additional information is essential to ensure that the predicted impacts are appropriately captured and that planned mitigation measures are effective. Without this, there is a risk that hydrologic and ecologic impacts to receiving environments may exceed predictions, with potentially adverse effects on aquatic species and habitat.	addition of storage parameters, could reduce confidence in the results. The use of steady state model results applied to very low flow conditions is already sufficiently conservative and consistent with groundwater industry standards. Finally, in practice, during operation, flow reductions will be addressed by comparison to a reference watercourse, which is experiencing the same seasonal and climatic conditions as the nearby creeks.	2. Support Trigger Action Response planning for adaptive management. 3. Assess shutdown and restart scenarios for drought or operational contingencies.	
C.9	*N/A*	N/A	This comment from July 7, 2025 Source's technical memorandum was not responded: Water Taking during Construction Activities The scoped PTTW application previously included a construction-phase water taking volume of 953 m^3/day associated with dewatering the 4 Pond excavation. In the May 2025 version of the PTTW application, this specific activity and its associated volume are no longer explicitly identified in Table 1-1. It is understood that the updated application may rely on steady-state groundwater modeling to estimate a more "conservative" (i.e., higher) overall dewatering volume, which could implicitly include this component. However, given the distinct timing and operational nature of the 4 Pond excavation dewatering, it is not clear whether this activity has been excluded, reclassified under broader underground dewatering, or otherwise accounted for. Clear documentation is needed to confirm that peak construction-phase demands have been fully captured and appropriately represented in the requested water takings.	The most recent PTTW Application includes all the takings required for construction and operations of the GBR AEX project. We remain confident that the work aligns with the permit application requirements for a Permit to Take Water (PTTW) and an Environmental Compliance Approval (ECA) in the province of Ontario. While the reviewer disagrees with this position, we have made every reasonable effort to respond to the concerns raised. We are unable to provide further clarification that would alter the reviewer's perspective and therefore consider our response complete. No additional comment will be provided on this matter.

1. **Executive Summary**

Client Name:	Kinross Gold Corporation	Project No: Great Bear	
Project Name:	Great Bear Gold Project		
Meeting Type:	In-Person [ ]	Virtual [X]	Hybrid [ ]
Location:	Virtual		
Time:	14:00 – 15:00 EDT		
Date:	November 19, 2025		
Executive Summary:	Meeting between Grassy Narrows First Nation and Kinross. Dialogue on free, prior and informed consent. Technical discussion on sulphate discharge, water management and environmental commitments. Kinross provided an update on AEX activities in regard to permitting and water use compliance. Data sharing and next steps in consultation were also discussed.		
Key Actions:	- Share updated ML/ARD reports when available for main mine - Prepare written submission on fish consumption rates and risk assessment methodology - Schedule follow up meeting on agreement and potential future funding		

2. **Attendance**

ANA:

Joseph Fobister
David Sone
Dan Mossip-Balkwill
Jackie Esmonde
Sydney Lang

GBR:

Luke Crosby
Eric Lamontagne
Aaron MacDonnell
Connor Devereaux
Ashley Moncrief
David Bursey (Bennet Jones)

Notes:

ANA – Quick introduction of team members. No one new that Kinross has not met before from ANA side.

Kinross – Most of the same team. Ashley Moncrief is our Environmental Manager and Connor Devereaux is our Permitting manager. Eric Lamontagne is also supposed to join the call. Eric is our senior project leader and most senior technical person on the project.

Kinross – Eric confirmed he is present on teleconference

ANA – Introduction from Joseph Fobester the chief negotiator for my community. Want to talk about our land protection team and our mandate comes from the people of Grassy Narrows. It was developed to protect the people, the water, the land and environment in Grassy Narrow's territory. My people have suffered from relocation racism flooding residential schools and the contamination of our water our culture has been under constant attack our spirituality was nearly wiped out through colonization my people did not give up our inherent rights. We did not give up our right to govern ourselves, we did not give up our traditional territory, our right to traditional trapping or hunting. We did not agree to have our rivers and land contaminated or poisoned, my community wants to secure a healthy environment for our children and those yet to be born. We agreed to share our land on conditions that we would continue to live our way. We have enacted laws to protect our land that extended beyond our reserve boundary is our traditional territory, this is our hunting area, our medicine, our food that is a place where we go to heal our people. Section 35 of the Canadian constitution recognizes and affirms the original treaty rights of the Anishinaabe people of Canada. These rights are constitutionally protected the United Nations declaration on the rights of Indigenous People have recognized a right to self-determination and we can move freely and we can freely determine our political status and governance. Industry must obtain free power informed consent before implementing measures that may affect us particularly regarding land and resource development and we call on you to respect our laws and our rights.

Kinross - thank you for that introduction. We originally requested the meeting and thought it would be a good opportunity to speak as we haven't done so in this format in quite some time and I appreciate we had an agenda that was prepared by Grassy Narrows and we're ready to speak to it if you want to move to those items.

ANA – we can proceed to the agenda, the first item on the agenda is to start that conversation around the need for free prior and informed consent and that relationship with grassy narrows. There is a clear ongoing request for a relationship with Grassy Narrows that's grounded in free prior and informed consent.

Kinross - We appreciate this and we've had this conversation before and you know we are we are not going to give that consent right contractually that's not something we're going to do. The provincial crown and the federal crown don't recognize the free prior informed consent right, they have policies to pursue that and to engage to try to seek to achieve consent but it's not an absolute right

ANA - so you're saying you won't honor the law of Canada and the laws of grassy narrows

Kinross - the law of Canada does not recognize a right of free prior informed consent the federal and provincial policies are to seek consensus which is what Kinross has done

ANA – I think we're going to have a problem as stated in the opening statement that we demand that you respect the laws of the land and the laws of our community

Kinross - we understand the position of grassy narrows on this matter we have a different legal interpretation, and we've had this conversation going on three years now and neither side seems it has changed their view in terms of legal interpretation.

Kinross – Also putting aside the legal interpretation Kinross has provided all the information to grassy narrows on this same level as LSFN and WFN so we've provided all the information so the practical implication of that demonstrates respect that the companies afforded in this case and also funded Grassy Narrows efforts to review the information as well

ANA - we haven't really had a fair opportunity to engage in this process because the project start four years before we learned about this uh this project.

Kinross - we've had this conversation before we believe that we've engaged with grassy narrows very transparently early upon our acquisition of this project we've provided every piece of information that we've provided to the other communities that we're consulting. From the back and forth and the letters that we've seen and that you've written in our responses we believe that grassy narrows does have a very clear understanding of the project activities, the project itself and what we've been up to so we do disagree somewhat but we acknowledge that there was a period of time before we own this property but since we've owned it we've engaged consistently and transparently since 2022

ANA - it's hard to engage with the speed this is moving because we have a lot of problems in the community we're dealing with. The ability to engage in a meaningful way is an ongoing problem because of some things you know we can't control and focus on this project.

Kinross - we understand there are challenges and that we limited means for us to address those admittedly one of the ways that we have attempted to address that is through capacity funding for advisors and experts to allow for review of the materials. We have also reached out and made offers of potential opportunities for us to help in community. It's something we remain open to a discussion beyond capacity funding through the agreement

ANA - Grassy Narrows dealing with a mercury crisis and other situations and our water was already contaminated and we need to have meaningful engagement to understand what other potential contamination may come from your operations.

Kinross - no additional contamination caused by our project is contemplated but we want to help you understand that. We want you to understand our project and our activities and we hope you'll understand it the way we do but that hasn't been the case to date but we're certainly open and will continue to share information, provide capacity support to help to understand that information and we think we've demonstrated that commitment to date

ANA – we have presented our expert reports and they disagree with some of your reporting.

Kinross – we agree there is disagreement amongst our experts on some of this and want to continue the discussion

ANA - we need to understand what you're going to put in our water and this is good segway to talk about point three in the agenda in regards to sulphate discharges. From the communications we know that this is a contaminant of particular concern. We have seen in some of the documents filed through the federal impact assessment process that indicate intention to address sulfate. Could you explain to us what is your commitment around sulfate levels and guidelines

Kinross – One clarification for the main project and IAAC process is there have been no commitments on sulfate discharge levels. We have covered desulfurization methodologies that we have included in the design of the project but not specific sulphate levels in the discharge. Our team can explain further some of the methodologies and technologies we're contemplating for the main project

ANA – In regard to advanced exploration you have ECA permit and for main mine presumable there would be an ECA permit that may address sulphate levels. Is Kinross indicating there is a sulphate objective for AEX but not the main project. Can you expand on AEX

Kinross – for AEX, we have made a commitment to meet the background concentrations of sulfate within the mixing zone of the discharge. We're also attempting to understand the relationship between sulfate and mercury in the Chukuni river watershed. We are considering attempting to replicate the riverbank study that's often referenced that was done in the Wabigoon watershed. We would look at synthesizing our effluent from the main mine and potentially mimicking the study in the same laboratory conditions. We had reached out and we were asking for some of the QAQC data and methodologies of that study as it would help us understand how to properly mirror that study in our conditions. If that information is available to us it will help us understand for our work.

For the main project we are modeling the potential of our project would have any impact on methylmercury production in the system and we have made significant commitments from the outset. This includes desulfurization of the tailings product which will make our tailings essentially NPAG. We are also looking at membrane filtration which is often reverse osmosis treatment for the process water which is the highest concentration of sulfate from the site from current modelling. These are significant capital investments that we're making to reduce sulfate concentrations now. One item to note is you can't selectively treat for sulfate if you treat for sulfate you remove all and you basically make distilled water. The by product of this is brine from membrane filtration which needs to be managed as well. This includes storage on surface so we're looking at it very seriously as we know it's a concern for the community. Those are the steps we are taking for the main mine. Again, for AEX we will meet background concentrations within the mixing zone but this is not technically feasible for the main project.

ANA - when you say you can't commit you are you saying you can't commit right now because you need to do more studies or you'll never be able to commit for the main mine

Kinross - from a technological perspective it would not be achievable is our view at this time. We have requested for detailed data supports from the Branfireun study which we've received one response from Grassy Narrows saying that they will not provide this information. There is also an External Technical Review that has been established by the federal government that will be reviewing the information provided in the Impact Statement.

ANA – We are hoping to gain an understanding of the recommendations that come out of that process and modeling work for the main mine when you share it with us.

Kinross – To clarify we will meet background but for the main project the mixing zone will be a bit. The objective for the annual average concentration for sulfate is about 400mg/L that was used as modelling assumption. The team is telling me its around 300m where we would meet background for the main mine under current assumptions.

ANA – so that is for the main project and sulphate of 400 mg/L

Kinross – the modelling looks at life of mine and where the effluent concentration will be the highest. The majority as previously mentioned comes from the tailings facility itself and also the destruction of cyanide. We need to use sulfate to destruct cyanide and all of this process water will be treated with membrane filtration

ANA – for the Grassy Narrows team it would be good to get this all in writing that there is this commitment with respect to achieving background concentrations for AEX. For the AEX achieving background within 300 meters where should we look to see that all in writing

Kinross - if the government shared a draft permit with you or proposed conditions around the AEX it is in there. It was a commitment we made directly to the provincial government for AEX. We have a draft condition in the ECA

for AEX. For the main mine you'll see it in the documents we're going to be sending to Grassy Narrows before end of year which are the technical supporting documents for the impact statement.

ANA – we need to see a copy of that and given that it's grassy narrows people who are going to be eating the fish downstream of project and the population the concern applies to

Kinross - it is our understanding that the province has shared that information. We can say we are not resisting this condition and don't think we have something formal that we could show you a declaration of non-resistance but you know we've accepted the draft permit conditions.

ANA - I think you acknowledged and think we can all agree there's been many areas of disagreement but this may an area where something can be done Grassy Narrows in response to their concerns

ANA - it sounds like Kinross is trying to get grassy narrows a letter making this commitment

Kinross - we can discuss further but it's going to be in our permit and we've agreed to the draft condition so I don't know what a further commitment would mean

Kinross – Additional clarification when you characterize a lot of things where we disagree and say nothing we can do. Kinross is taking comments seriously and doing its best to deal with the disagreements about science but different points of view by experts is not something we can address.

ANA – we are not going to agree today on a summarizing statement about how things are going but we are hearing Kinross is committed to not increasing sulfate in the Chukuni River above background within a few meters of the discharge point for AEX and to not increase above background in the Chukuni river during the life of the mine after the mixing zone of a few hundred meters. Grassy Narrows expects anyone who makes a commitment would put it in writing and stand by it.

Kinross - we're making the commitment to the government and will be a permit condition. Respectfully the commitments being made to MECP and we're confirming that to you and providing additional information.

ANA – it a very important commitment to a key concern that Grassy Narrows has made and it would be an important part of building the relationship and the trust

Kinross - We're listening, we just want to make sure we have an accurate report of what is being discussed.

ANA – due to time we should move questions about the portal construction. We know from the media reports that there's been some steps taken towards construction of the portal. The portal construction was in the permit to take water that was the subject of the successful leave to appeal application and was later withdrawn. Some of the water takings were related to the construction of the portal. What work have you completed and what are you working on and does it involve the taking of water particularly taking of water more than 50,000 per liters per day

Kinross – we can assure you that everything that we've done to date has been reviewed and inspected and is within the parameters of the existing permits that we do have today. We have completed as much as we could do without moving water. There are ponds that we have stored water and have been working with MECP understanding snow conditions given that we don't have any authority to move water. Storing water on site isn't what we want to do responsibly we would like the permission to be able to move water so that we're not creating any additional risks but right now there is no movement of water on site over the 50 000 liters a day. We have dug out the storage ponds and storing water on site. We are also doing grading to ensure the water drains to the ponds as opposed to off site. General earthworks ongoing and utilities that would fall under the closure plan. Until we have the ECA and the PTTW it's just those activities of moving materials and grading and creating pads.

ANA - Have you completed the box cut and dug out the portal?

Kinross – Yes, we've created the box cut but not to the portal. Once we break collar to go underground is where we would need the ECA and the dewatering activities for pumping water out of the area. so the surface materials have happy route until you break collar to go underground has been removed for the box cut and then the collar so once we break to go underground is where we need the ECA for the dewatering activities

ANA – To follow up you are digging but not underground. You haven't been doing underground but have you got into bedrock?

Kinross – for the portal itself we aren't going at depth yet we've only exposed the bedrock

ANA – At the collar location you've removed all the overburden down to the bedrock in the box. What is happening with rain water or water that collects in the box cut

Kinross – water is collecting there right now. We have also shot created and bolted the sides for stability of the rock features but there is no work beyond that going in that area until we can move the water out

ANA - how deep is this area from ground level?

Kinross – do you have this figure off the top of my head but we can follow up

ANA - how is this different from what you proposed to do in the PTTW application

Kinross - we're not pumping water out of here above the 50,000 L/ day limit and we're not pumping water off-site

ANA - so are you not pumping water or you're not pumping water off-site

Kinross – Both, we're not allowed to mechanically pump water beyond the threshold that was previously mentioned. The only thing that we're allowed to do is under the 50 000 liters/ day which is tracked and it's for dust suppression mitigate other potential environmental impacts. Water used for dust suppression stays on site collects in the same ponds referenced earlier.

ANA – Can you send the information about the depth, the amount of water being taken or pumped within the site on daily basis.

Kinross - Water for dust suppression we have the data and will provide

ANA - Our experts that we've been working with need ML/ARD reports, data and to evaluate potential contaminants that could be generated by this project and that they can't assess what kind of treatment is needed for example or what the impacts would be on fish, people, environment without those studies being completed

Kinross - all of this data and reports are completed and it's with the MECP. They've asked to get this data and be the ones that that exchange it with Grassy Narrows. For the AEX that's the updated metal leaching and acid rock drainage assessment report but there's another more extensive report for the main mine that will shared in December with ANA for the Impact Statement.

ANA – Understand December okay thanks for drawing that distinction. We have been receiving some of the chapters that you've been submitting and some technical reports as part of IAAC process. So these reports will be shared in similar fashion.

Kinross - As it as it becomes available we will provide it to ANA prior to sending in the formal submissions to IAAC

ANA - We touched on it previously about Grassy Narrow's concerns and how the company is responding to what our experts are saying and how the company has responded to date. It certainly appears to the community that we have experts who are raising you know significant concerns and Kinross disagrees with what the experts are saying. It is helpful to hear today talking about sulfate and what the company is doing around that but we do note that from the community's perspective it hasn't felt like a good and meaningful process to date

Kinross - yes we acknowledge and as mentioned earlier we acknowledge our experts do disagree on some of technical aspects. We shared information and what we have done to address these and we've already spoken about one which is the advanced exploration permit having a sulfate discharge limit. We have exchanged a lot of letters back and fourth and are at a point there's a lot of disagreement between our experts on some things but I don't think it's fair to say that we have not thought about them or attempted to address any of them. We have certainly made in our view a lot of reasonable changes to our project to address these issues. Some of the items we do not agree with and cannot commit to. We recommend we continue this discussion once you have had a chance to review the addition information from MECP.

Kinross - the way it was presented, reasonable people can reasonably disagree and reasonable experts could reasonably disagree but beyond that Kinross for the AEX project is following leading industry practice, it's not just experts disagreeing, Kinross is listening and doing a lot of things that are far beyond what other comparable situations

Kinross – we will add that from our perspective it will be the most heavily regulated conditioned AEX project in the province. Kinross realizes water quality is an important issue for all the communities and particularly Grassy Narrows so we're looking at what can be done and the sulphate discharge is one example.

ANA – a lot can be said about it and the disagreement is on display now but we hope with the insertion of additional Ontario personnel into the process that might help some of the communication

Kinross – we have been in discussions with MECP to engage directly with Grassy Narrows. The other alternative is there's another call similar to this. It always helps to talk and understand the other side because maybe the disagreement isn't as big as the perception

ANA - on that topic is there anything else Kinross wanted to say since you called the meeting

Kinross - we wanted to check in as we haven't done a meeting like this in a while we do have some specific questions particularly us in terms of status of the TK work that's been ongoing there's a couple of requests to validate information and reports we wanted to ask about those directly because we haven't seen any updates or received responses to some of those we did want to ask again specifically to share the riverbank backup study information and we also wanted to give an opportunity to the community and the land protection team to ask us some of the questions we've been discussing and it appears kind of news to this team that we committed to a sulfate limit for AEX for example.

ANA - we can give you some quicker responses to the questions posed. If you are planning to replicate the professor Branfireun's method we think the most effective way to do that would not be to the see the QAQC on his data but rather to send him a copy of your work plan for the experiment and to invite him to review it and others. Our expectation is that you would be sharing this type of information. He would be the best place to review your methodology and to tell you whether you are effectively replicating his methodology. In regard to the plan to use Chan et al 2005 fish consumption rates for your risk assessment and asked grassy narrows to validate. At this time Grassy Narrows does not believe that's a valid method and we are preparing a written submission to you explaining the reasons for that. For the TK study we have previously communicated that the work on that is

ongoing but there is not current project like that and it will take years not months to complete. We will let you when there is information available to share

Kinross: do you intend to share that with us

ANA: there's nothing the community could share at this time as it is in the very preliminary stages and as we communicated at the beginning the land use and occupancy studies typically take three to five years. It will also be up to the community on what is shared with Kinross from this study.

Kinross: Follow up question about the human health risk assessment. You had mentioned that our methodology or assessment may not be correct but will your response include consumption rates that we should consider for Grassy Narrows? You have disagreed with the Chan et al secondary source that we utilized but it would be helpful if you can provide the appropriate fish consumption rates

ANA: We understand you are using that as an input for the risk assessment that we haven't seen yet. That is just one part of the bigger assessment that needs to occur.

Kinross: Correct that's one piece of the overall human health risk assessment. That document comes at the end as it takes into account results from numerous other studies in the Impact Statement.

ANA: We haven't seen the methodology yet but you did share how you plan to model mercury and again we think it's best to give input early and integrated early so that we don't get to the end with a product that you consider final and then we say well you follow the wrong methodology. If the methodology can be shared sooner than later for feedback.

Kinross – We don't see an issue with that as we follow the federal guidance and IAAC TISGs but we'll circle back on that one for sure

ANA - Grassy Narrows has been quite clear hat out of the box approaches for this unique situation may be required rather than most instances whether they're provincial or federal were not developed taking a community that's been poisoned by mercury downstream of the project into account. This is important in all aspects whether it's the fish consumption guidelines or human health risk assessment work

ANA: we're a little bit over time any additional follow up before we adjourn. I'm not sure if we got all of those questions so we can follow up with an email if that is okay. The other item to touch on quickly is the agreement and we were going to come back and talk about some other pieces of it and potentially future funding. Propose that we schedule another call with a smaller group for that discussion.

Kinross: We are available in December to facilitate a follow up meeting. Appreciate everyone taking the time and see value in these conversations, we don't always agree on everything but I do think there's value in hearing each other's sides, thank you

1. Introduction

Great Bear Gold has asked for Grassy Narrows' comments on the use of fish consumption data from a 2005 report by Dr. Laurie Chan in the context of a risk assessment for the federal Impact Assessment.

A fulsome response will require Great Bear to share its proposed risk assessment methodology with Grassy Narrows, and will also require time for Grassy Narrows to obtain expert review. In addition, accurate figures for current fish consumption would require a robust current consumption survey in Grassy Narrows with a community validated methodology. However, on a preliminary basis, this submission outlines significant concerns with any reliance upon data that reflects consumption rates that are far below historical rates because of the decades-long mercury crisis. To the contrary, this Project should base its risk assessment on Grassy Narrows' Treaty-protected right to fish and its goals of remediating the river system to such a degree that this right can be fully exercised.

In addition, we outline the need to consider the unique risks to Grassy Narrows. Grassy Narrows members have already been exposed to high levels of mercury and expert evidence establishes that they cannot safely be exposed further.

We repeat our request that Great Bear share its proposed risk assessment methodology, guidelines and proposals for any other studies and assessments (including those with respect to methylation) in advance for Grassy Narrows' review. We reserve the right to make further comments after we have received details of the proposed risk assessment methodology and obtained expert advice.

2. Risk assessments and guidelines must be protective of the full scope of Grassy Narrows' Treaty protected right to fish

a) The Treaty Right to Fish

The right to fish and eat fish safely is an inherent right given to the people of Grassy Narrows by the Creator. The practice of fishing and consuming the fish is integral to Grassy Narrows' self-determination. These rights are recognized and protected internationally by the UN Declaration on the Rights of Indigenous Peoples, to which Canada is a signatory. Canada has committed to full implementation of the Declaration. The right to fish is also a Treaty right recognized and protected by section 35 of the constitution of the Crown.

Indeed, Treaty #3 Commissioner Simon Dawson reported to the Legislature that:

> "I am in a position to say that, as an inducement to the Indians to sign the Treaty, the commissioners pointed out to them that, along with the land reserves and money payments, they would forever have the use of their fisheries. This point was strongly insisted on and it had great weight with the Indians, who for some years previously had persistently refused to enter into any Treaty."

Indigenous fishing and fishing rights are different from the rights of the general population, and even different from other subsistence fishers. The US Environmental Protection Agency (EPA) developed a guide for subsistence fishing with the collaboration of representatives from Native American Tribes. It indicates:

> "EPA recognizes, however, that Native American subsistence fishers are a unique subsistence fisher population that needs to be considered separately. For Native American subsistence fishers, eating fish is not simply a dietary choice that can be completely eliminated if chemical contamination reaches unacceptable levels; rather eating fish is an integral part of their lifestyle and culture. This traditional lifestyle is a living religion that includes values about environmental responsibility and community health as taught by elders and tribal religious leaders. Therefore, methods for balancing benefits and risks from eating contaminated fish must be evaluated differently than for the general fisher population" (US Environmental Protection Agency, 2000, as quoted in Mergler, 2015, p. 23).

These observations apply equally to Grassy Narrows.

Caution must be taken in using data that does not reflect historical rights and current trends. Fish consumption is growing in Grassy Narrows. As part of the community's commitment to restore its cultural practices, younger people are learning to fish and eat what they catch. Fishing is becoming very popular. This has many benefits for Grassy Narrows' wellbeing, way of life, and nutrition. Regulatory decisions need to keep these young fishers safe while allowing them to practice their Anishinaabe way of life and support the safe revival of the fishery.

It is not acceptable, nor is it legal, to allow Grassy Narrows' fish to become, nor to remain, contaminated in a way that prevents the meaningful and safe exercise of their inherent, Aboriginal, and Treaty rights.

b) Grassy Narrows fish consumption and use prior to mercury

For countless generations, and immediately before mercury pollution came to light, fishing was a cornerstone of Grassy Narrows' sustenance, livelihood, and way of life. Grassy Narrows had

90-95% employment, mostly in the sport and commercial fishing industries (Usher, 1979, Vecsey, 1985).

Most Grassy Narrows people who worked in the fishing industry ate fish for lunch and then brought home fish for their family to eat at dinner.

In the 1960s the average Grassy Narrows person ate 200 lb of fish each year, with the vast majority of that fish being walleye (Usher, 1979).

c) Grassy Narrows' fish consumption reduced due to mercury

Grassy Narrows people have suffered from the mercury contamination of their fish, which they first learned about in 1970. Grassy Narrows' fish remain mercury contaminated, and mercury levels in walleye have not improved in a statistically significant way in the English River near Grassy Narrows since the early 1990s (Neff et al, 2012). As a result, the commercial fishery remains closed, and the Ontario Ministry of Environment Conservation and Parks continues to issue highly restrictive consumption advisories.

The mercury contamination of Grassy Narrows' fish has led to a dramatic reduction in the amount of fish that Grassy Narrows people eat, a dramatic decline in Grassy Narrows' sportfishing industry, and a cessation of the commercial fishing industry.

By 1978, Grassy Narrows fish consumption had declined by nearly 90%, and more recent consumption studies reflect a 95% decline in fish consumption compared to levels before 1970 (Chan, 2005; FNFNES, 2014).

Current fish consumption levels reflect the response of Grassy Narrows people to a high level of pollution, and a high level of impact on their health, wellbeing, rights, livelihood, environment, and way of life. They reflect an ongoing and devastating mercury crisis. Respect for Grassy Narrows' Treaty rights, in particular its right to fish, will require a reversal of this trend rather than a continuation or worsening of this state of affairs.

d) Remediation goals

Grassy Narrows has long demanded that the English River and its tributaries be returned to their uncontaminated state. In 2017 the Government of Ontario committed to partner with Grassy Narrows in the timely and comprehensive remediation of mercury and other contaminants in the English and Wabigoon Rivers.

Grassy Narrows' primary remediation objective is to:

1. Reduce mercury concentrations in fish traditionally consumed by Indigenous peoples on the river system to levels that are safe for subsistence consumption by present and future generations. Subsistence consumption includes not just the species and amounts of fish, but also the manners in which the fish were consumed and the locations in which they were fished before the river system's contamination by mercury.

   For Grassy Narrows this means reducing mercury concentrations in fish in the English River system to levels which are safe to consume 200 lbs of fish per person per year, with the large majority of that fish being walleye larger than 45cm. If that is not possible, then mercury concentrations should be reduced to pre-contamination background levels.

Additional remedial objectives support the primary objective and include:

2. Eliminate significant ongoing and potential future sources of mercury to the English-Wabigoon Rivers system from the Dryden Mill Site and vicinity, and other potential industrial sources.

3. Eliminate ongoing, and potential future, sources of mercury to the English-Wabigoon Rivers system from mill contaminated sediments (including banks, wetlands, floodplains, and wood wastes), with priority given to those contaminated sediments that contribute most to mercury levels in fish.

4. Reduce mercury uptake in the food chain by reducing mercury methylation and bioavailability.

5. Reduce mercury concentrations in sediment, water, and biota to levels that would be present if there were no discharges from the Dryden mill and other industrial sources.

6. If other contaminants associated with the mill pose a risk to human health and/or the environment, then reduce levels of those contaminants in fish and other biota with focus on fish that are consumed by Indigenous peoples.

There are further objectives with respect to employment and benefits for Grassy Narrows people, respect for Grassy Narrows' Indigenous knowledge, and respect for Treaty rights.

While the formal remediation objectives for the project have yet to be set by the Minister, there has been near consensus at the English and Wabigoon Rivers Remediation Panel on these, or similar, objectives.

All decisions with respect to pollution in the river system must be made in a way that supports the timely and comprehensive achievement of these remediation goals.

e) The Chan Report (2005) is not a valid basis for risk assessment

Great Bear proposes to use the Chan Report (2005) as a basis for estimating Grassy Narrows fish consumption. The Chan Report is flawed and should not be relied upon for risk assessment.

Chan's report merely corroborates the fact the Grassy Narrows people reduced their fish consumption by approximately 90% in response to the brutal impacts of a decades-long and ongoing mercury crisis. This standard, which reflects sustained attacks on Grassy Narrows ability to enjoy their Treaty right to fish, is not a benchmark to guide future industrial activities. To the contrary, it must be reversed. Any reasonable risk assessment should protect Grassy Narrows right to fish and therefore must be based on their 1960s fish consumption rate (200 lb of fish each year, mostly walleye). Anything less is inconsistent with Grassy Narrows' goal and Ontario's legal obligation to comprehensively remediate mercury in the English River system and support Grassy Narrows's ability to safely practice their right to fish.

However, even if the Chan Report's dramatically reduced fish consumption rates are used, such rates still result in mercury exposure levels in Grassy Narrows that, on average, exceed US EPA guideline levels, and often exceed Health Canada levels. For example, Dr. Mergler (2015) considered mercury exposure using Dr. Chan's data and found that in Grassy Narrows in 2003, the average mercury intake over the year was 0.2µg/kg body weight/day, with men having higher average intakes compared to women (0.3 µg/kg body weight/day vs. 0.1µg/kg body weight/day).

There is an important caveat to using this data. Average intake data included people who do not eat fish; if the analysis had included only fish-eaters, the average mercury intake would have been higher.

By season, the highest mercury intake was by men in summer and spring (3.7 µg/kg body weight/day). Approximately 25% had estimated intakes above the Canadian TDI and 41% were above the US-EPA RfD. The average mercury intake for Grassy Narrows women in 2003 was above the US-EPA RfD of 0.1 µg/kg body weight/day.

As Mergler shows, even at Chan's dramatically reduced fish consumption rates, mercury exposures in Grassy Narrows often exceeded established (not site-specific) guideline levels.

f) Probabilistic and seasonal approach to fish consumption estimates

A reliable risk assessment process must follow a rigorous probabilistic approach. Some shoddy risk assessments use only average exposure levels. This approach is especially problematic in Grassy Narrows where many people have been forced to dramatically reduce their fish consumption due to mercury. Reliance on averages obscures and masks the most serious risks facing those who continue to practice their right to fish.

It is critical to account for the full range of fish consumption rates and exposure levels within Grassy Narrows. For example, Chan calculated that the average yearly local fish consumption in Grassy Narrows in 2003 was 20g/day, but in older men (+61 years of age) consumption averaged 60g/day. A community average approach would fail to identify and address the three-fold higher exposure for male Elders and would likely fail to protect them.

Even in Chan's relatively small sample size, which made no effort to target heavy consumers of fish, there were individuals who experienced seasonal exposure 12x the mean. While Chan's mean 2003 hair mercury was 1.3 µg/g, the highest individual hair segment was 15.5 µg/g. In 2004, Harada reported that one person had a concentration of 25 µg/g (Mergler, 2015, p.52). Again, simply using the mean would not protect the individuals most in need of protection – those who continue to practice their right to fish regularly.

The pattern of fish consumption in Grassy Narrows includes periods of high fish use when out on the land at family cabins and landuse areas. Walleye make up approximately 90% of fish consumed and large fish are favoured for their high yield and ease of preparation. While 45 cm length-standardized walleye in a body of water may have 0.7 ppm (µg/g) mercury, larger walleye may have a 2 ppm or higher.

Importantly, the specific fetal impacts and impact upon pregnant persons must be taken into account. For example, a pregnant person who weighs 100 kg may eat 500g/day of flesh from a large walleye containing two ppm mercury each day for four days while at their family cabin. This would translate into exposure of 10 µg/kg/day, many times above both EPA and Health Canada guideline levels, for a period of time that is critical in the development of the fetus.

Again, simply using averages with respect to consumption and fish mercury would obscure and fail to protect against this important risk to the next generation.

> "There is now a very large number of studies on prenatal exposure to mercury and adverse health effects, most notably on children's neurodevelopment" (Mergler, 2015, p. 34). Furthermore, "A growing number of birth cohort studies show that the foetus is particularly sensitive to methylmercury neurotoxicity and even very low concentrations of exposure can affect future cognitive capacity and behaviour" (Mergler, 2015, p. 48).

Fetal and early childhood impacts can be severe and lifelong. Scientific evidence consistently shows that prenatal and early childhood exposure to mercury is linked to lasting reductions in children's cognitive abilities. These deficits persist into adolescence and adulthood, with higher prenatal mercury levels associated with increased rates of learning disabilities and long-term impairments in brain function and intelligence. While current reference doses are meant to protect fetuses and children, they may not be sufficiently protective because mercury concentrations in cord blood can exceed those in maternal blood (Mergler, 2015, pp. 14-15).

"A 22-year follow-up study of children of mothers with high mercury exposure shows that there are still deficits in major domains of brain function as well as general intelligence in relation to their cord blood mercury concentrations; the geometric mean of their current blood mercury concentrations was 2.53µg/L and hair mercury 0.68µg/g. The lowest reference dose for the protection of foetus and children is the US EPA reference dose (5.8 µg/L blood mercury; 1 µg/g hair mercury)" (Mergler, 2015, p. 14-15).

A risk assessment should account for heavy land users/fishers, higher mercury levels in large fish, the practice of eating large fish, the patterns of fish consumption, and the most at-risk segments of the Grassy Narrows population. It should use a methodology capable of protecting all Grassy Narrows people and should be robust at least at two standard deviations from the mean.

3. Guidelines for mercury consumption must be site-specific

a) Tailored Impact Statement Guidelines requires no increase in mercury methylation downstream of the Project

The starting point for Great Bear's risk assessment is the Impact Assessment Agency of Canada's (IAAC) Tailored Impact Statement Guidelines (TISG) (2024), which requires

Great Bear to demonstrate no increase in methylation of mercury in the waters downstream of the project. The TISG directs that the Impact Statement must:

> "describe the methods for **ensuring that the rate of methylation of mercury downstream of the Project does not increase as a result of the Project**, taking into account physicochemical parameters, biological parameters, and chemical constituents of surface water that can contribute to the methylation of mercury" (IAAC, 2024, p. 59, emphasis added).

IAAC also directs Great Bear to take into account existing mercury exposure in Grassy Narrows and to ensure no increase in methylmercury in the fish, including those fish consumed by people of Grassy Narrows. The TISG states:

> "Efforts should be made to ensure that existing methylmercury exposure in nearby human receptors are factored into the HHRA, particularly when assessing impacts on Grassy Narrows First Nation community members in the HHRA." (IAAC, 2024, p. 90).

> "The Impact Statement must describe the proposed mitigation and enhancement measures for any potential effects on the health of Indigenous Peoples. In particular, the Impact Statement must: …identify mitigation to **avoid human health effects caused by changes to the quality of country foods from potential changes in mercury methylation rates downstream of the project site**" (IAAC, 2024, p. 93, emphasis added).

No matter what guideline is chosen to assess risk of mercury exposure for fish consumption for the Great Bear project, the project cannot contribute to any increase to mercury methylation downstream.

b) No additional exposure is safe for Grassy Narrows

Grassy Narrows is unique due to their high past, and ongoing, exposure to mercury. Indeed, in a nationwide Health Canada mercury biomonitoring programme running from 1970-1992, among 71,842 measurements from 38, 571 individuals the highest mercury reading recorded was a man from Grassy Narrows who had 660 ppb mercury in his blood/hair samples (Philibert et al, 2020).

Given these unique circumstances, standard risk assessment procedures do not apply because they have been developed as guidance for lifetime safe fish consumption in the general population, which has not been exposed to high levels of mercury. Those guidelines are not

protective for a community like Grassy Narrows, which has already been exposed to “high concentrations of mercury in fish for many years and individuals and the community are suffering the effects” (Mergler, 2015, p.24).

According to Dr. Donna Mergler, professor emerita and renowned expert in mercury’s impact on human health, “When estimating the risk for mercury poisoning in Grassy Narrows, it is necessary to account [for] past exposures (including prenatal exposure), as well as present exposures" (Mergler, 2015 p.27).

Furthermore, “further exposure will build on the damage already present. The guidelines for mercury intake refer to ‘over a lifetime’. If exposures have been higher in the past than at present, the intake guidelines do not apply since over the lifespan, one’s intake will be higher than those recommended by the guidelines” (Mergler, 2015, p. 25).

Based on detailed review of decades of research on mercury in general and on the impact of mercury poisoning in Grassy Narrows, Dr. Mergler’s expert opinion is that “There is no question that the mercury already present in the Grassy Narrows area poses important risks to health and well-being to the community and that any further addition of mercury would increase that risk” (Mergler, 2015, p. 27).

After reviewing the extensive scientific literature on mercury and on Grassy Narrows, Mergler concludes that “Any increase of exposure to this already ‘sensitive’ community would further compound the harm to the health and well-being of the present and future generations” (Mergler, 2015, p. 53).

In summary, Grassy Narrows people are unique because of their past and ongoing mercury exposure. Many Grassy Narrows people have already exceeded the lifetime safe exposure to mercury amount and are experiencing intense impacts to their health and wellbeing as a result. Grassy Narrows requires that the mercury levels in their fish, and the consequent exposure to Grassy Narrows people be reduced. No increase to the levels of mercury in fish in the English River and its tributaries is safe for Grassy Narrows. Indeed, the levels of mercury in fish must decrease.

c) Existing guidelines do not apply

As noted above, Dr. Mergler’s expert opinion is that existing intake guidelines for mercury exposure “do not apply” for Grassy Narrows since community members have experienced high past exposure, which the guidelines do not account for. Grassy Narrows requires a more protective, site-specific methodology that prohibits any activity that does not contribute to the

return of mercury levels to their pre-contamination background level or support the achievement of the remediation objectives.

This protective, site-specific risk assessment methodology and guideline should be developed with Grassy Narrows and their experts and should obtain Grassy Narrows' consent.

d) Alternative guidelines

Should Great Bear refuse to develop protective site-specific guidelines, despite the overwhelming expert evidence about the unique circumstances for Grassy Narrows, the most protective guidelines available must be used a starting point and then adapted to reflect the unique situation in Grassy Narrows. As noted above, Dr. Mergler's expert opinion establishes that "a population that has already suffered effects from mercury contamination and other harmful risk factors for poor health may also be considered 'sensitive'" (Mergler, 2015, p.52). "Persons whose systems have already been altered by previous exposures are more sensitive than the general population" (Mergler, 2015, p.47). Therefore, unlike the general population, in Grassy Narrows all people must be considered 'sensitive' and child-bearers and children must be considered extra sensitive to mercury.

With respect to fish mercury concentrations, Health and Welfare Canada in 1979 recommended a limit of 0.2 ppm mercury in fish for consumption in Grassy Narrows. Nearly all 45 cm length-standardized walleye in the English River system exceed this threshold.

However, the USA EPA value for fish derived specifically for subsistence fishers is far more protective than Health and Welfare Canada's and is set at 0.049 ppm (Mergler, 2015 p.10).

There are now multiple mercury intake guidelines for the general population. As Dr. Mergler explains:

> "The guidelines were developed to recommend **tolerable daily intake (TDI) or weekly intake (TWI)** of mercury. The Canadian provisional tolerable daily intake for pregnant women, women of reproductive age and infants of 0.2µg/kg body weight/day is twice the US EPA of 0.1µg/kg body weight/day and slightly higher than the proposed revision of the FAO/WHO reference dose (0.19 µg/kg body weight/day) (see section 2). The US EPA reference dose is based on **cord blood concentrations**, while the JECDA and Canadian recommendations are based on **hair concentrations"** (Mergler, 2015, p.44).

The US-EPA uses the term Reference Dose (RfD), defined as "an estimate of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects during a lifetime" (Mergler, 2015, p. 21). Dr. Mergler notes that,

> "there is scientific evidence to support that the EPA RfD, based on cord blood, may be too high since cord blood contains 60-70% more mercury than maternal blood, and approximately 100% higher for the upper 5% and recent studies have observed neurotoxic effects in children at these levels of prenatal exposure" (Mergler, 2015 p.11).

Canada uses Toxicity Reference Values (TRVs) to derive Total Daily Intake, (TDI) defined as "the maximum amount of a chemical that can be ingested on a daily basis over a lifetime without increased risk of adverse health effects'" (Mergler, 2015, p.26).

Mergler notes that "The Canadian Total Daily Intake is based on maternal hair at birth and did not take into account placental bioconcentration and thus did not account for the fact that hair mercury concentrations decrease over pregnancy" (Mergler, 2015, p.23).

Peer reviewed scientific publications by Mergler and her team have found health impacts associated with mercury in Grassy Narrows at levels of exposure below the Health Canada guideline level (Mergler, 2025; Philibert et al, 2022, 2024a, 2024b).

Mergler comments that,

> "Given the information on estimated methylmercury intake from past and present exposures in Grassy Narrows, there are already effects on their health and well-being from mercury exposure and the EPA RfD would be more suitable for the Grassy Narrows population." (Mergler, 2015 p.22).

In summary, the US EPA guidelines for fish mercury and human mercury intake are the most protective existing guidelines and therefore the most relevant to Grassy Narrows. However, even the US EPA guideline is not sufficiently protective against fetal impacts and do not take into account high past exposure. Mergler concludes that "All of these reference doses are high for Grassy Narrows since the population has already been exposed to levels that are higher, and in many cases, considerably higher than these" (Mergler, 2015 p.44).

4. Conclusion

As Grassy Narrows has emphasized from its earliest engagement with Kinross, one-size-fits all approaches fail to protect Grassy Narrows because of its unique circumstances. Grassy

Narrows' mercury crisis, cumulative impacts, and site-specific considerations must be adressed to create tailored solutions that ensure that the impacts of the past are not repeated, prolonged, or compounded. This applies to the risk assessment.

The expert evidence shared here, supports the following conclusions:

1. Grassy Narrows people used to fish and eat fish extensively on the English River system before the mercury crisis, mostly large walleye (200 lb/person/year).
2. Grassy Narrows people have been forced to dramatically reduce their fish consumption due to mercury contamination.
3. All regulatory decisions about industrial activities impacting on Grassy Narrows must support the return of Grassy Narrows' fish to safe levels of mercury so that Grassy Narrows can restore and resume their pre-contamination fish consumption, livelihood, and way of life.
4. Grassy Narrows people have already exceeded their lifetime tolerable exposure to mercury and are experiencing intense impacts as a result.
5. No amount of further exposure or increased mercury levels in their environment or fish is safe for Grassy Narrows. Mercury levels must be reduced.
6. Existing mercury guidelines do not apply for Grassy Narrows, but if Kinross insists on using existing guidelines rather than site-specific ones, the US EPA guidelines are the more appropriate starting point.
7. The outcome of the risk assessment must result in measures that are protective of those who eat the most fish in Grassy Narrows, those at most risk, the practice of eating large fish, and the seasons / community events where they eat the most fish.

As Grassy Narrows has noted elsewhere, it is premature to assess risk for this project because the ML-ARD studies and reliable water quality models required to reliably quantify which contaminants will be generated by the project, and in what quantities, have yet to be completed or they have not been provided to Grassy Narrows. Without that information the effectiveness of the water treatment plant and other mitigation measures cannot be assessed, nor can the risks and impacts on the receiving and downstream environment and people.

Overview	29
1. Mercury is highly toxic to human health. Impacts include foetal and child development, neurological disorders and cardiovascular changes.	30
2. Adults can be impacted at levels well below the old threshold level for risk of 50 µg/g in hair.	32

PAGE

3. Fetuses and children can be impacted at far lower levels than adults 34
4. Mercury is bio-concentrated across the placenta. 35
5. Population level impacts can be found at much lower levels of exposure than clear individual impacts 36
6. Developmental impacts of mercury have life-long impacts. 37
7. The health impacts of mercury exposure in adults can take a long time to manifest and can be long lasting and degenerative. 40
8. Fish is the most important source of mercury in humans. Other sources of mercury in humans include fish eating wildlife (ducks, otters, etc.) and dental fillings 42
9. In 1979 the Health and Welfare Canada recommended a limit of 0.2 ppm in fish as a fish consumption limit for Grassy Narrows and White Dog. 43
10. The Canadian reference dose for preventing fetal neurotoxicity and developmental impacts is double that recommended by US EPA. 44
11. Eating fish has a number of important health benefits. 44
12. The Ontario Guide for Sport Fish Eaters 47
13. People who have already experienced elevated mercury exposure 47
14. Conclusions with respect to Grassy Narrows 48

Appendix A – Curriculum Vitae

INTRODUCTION

I am a professor emerita at the *Université du Québec à Montréal* (UQAM), where I was a professor in the Department of Biological Sciences from 1970 to 2006. I hold a doctorate in physiology from McGill University. I am a former chair of the department (1982-1984), head of the doctoral program in environmental sciences (1993) and chair of the UQAM Institute for Environmental Sciences (2001-2003). I founded the Center for Interdisciplinary Research on Well-being, Health, Environment and Society (CINBIOSE) in 1985, and was director at different periods until 2000. From 1998 to 2013, I was director of the CINBIOSE World Health Organization-Pan American Health Organization Collaborating Center for the Prevention of Work and Environment-related illnesses. I was co-coordinator of the Latin American Community of Practice in Ecosystem Approaches to Human Health (2005-2013). Since 2008, I head the pan-Canadian research team on Gender, Environment and Health. I have been a member of the Quebec Council for Science and Technology (1984-1989) and the Science Advisory Board of the International Joint Commission of the Great Lakes (2001-2011). My teaching, research and writing have focused on the early neurotoxic effects in humans of environmental pollutants generally, including mercury. In 2006, I chaired an international scientific group which wrote a consensus document on mercury and human health. I have authored over 150 peer-reviewed scientific articles, including 50 scientific papers on the subject of mercury exposure and effects in freshwater fish-eating populations. I have given keynote addresses on mercury and human health at major international conferences and numerous presentations on the subject at national and international meeting, including the Office of Science and Technology Policy of the United States' White House (1988). I have written reports on mercury and health as it relates to the members of Grassy Narrows First Nation. My curriculum vitae appears in Appendix A of this Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare an expert report that responds to several questions. I am solely responsible for the preparation of this report.

QUESTIONS

1. For the documents referred to below, please indicate if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto.

A. The Grassy Narrows-Earthroots request, dated January 2014, of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May, July, September and November 2014 insofar as they relate to your area of expertise and the subject matter for your report.

B. Literature Review of the Mercury Disability Board, dated September 2010. This document (consisting of two reviews) is referred to in the September 2014 submission.

1.1 For the documents referred to below, please indicate your views on them to the extent they relate to the subject matter of your expert report and are within your area of expertise:

C. The article by Harada, et al. entitled "Mercury Poisoning in First Nations Groups in Ontario: 35 Years of Minamata Disease in Canada" (translated from the Japanese version published in the Journal of Minamata Studies in 2011).

D. The article by Takaoka, et al. entitled "Signs and Symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" published in the journal Science of the Total Environment in 2014.

2. Regarding the subject of mercury and human health:

a. Is mercury toxic to humans? If so, on the scale of toxic substances in the environment, where does mercury rank in terms of overall toxicity risk to humans?
b. If so, what are the clinical human health impacts of mercury?
c. Does exposure to mercury increase the risk of other health problems developing and, if so, identify those other health problems?

3. At what levels of exposure to mercury have adverse clinical health impacts on adults been documented in the scientific literature?

4. Does exposure to mercury affect the development of fetuses and children and, if so, what are the effects, and for what duration of time, if any, will those effects persist? At what exposure levels have these developmental effects been documented in the scientific literature?

5. Are there sub-clinical effects:

a. *In a community where mercury-related neurologic clinical disorders are present, could there be other persons with sub-clinical signs and symptoms?*
b. *What is the nature of these effects at each exposure level that have been documented in the scientific literature; and*
c. *Are developmental effects of mercury exposure affected by low socio-economic status based on such factors as education, income, etc.?*

6. *What are the sub-clinical population level effects, if any, of exposure to mercury? Compare these effects to individual clinical effects and to the mercury levels at which they are found? Comment on the nature and severity of the effect of these impacts at a community level?*

7. *Does mercury bio-concentrate across the placenta and, if so, what is the average concentration factor? What is the concentration factor at the 95th percentile?*

8. *Is there a delay in the manifestation of health effects following exposure to mercury? How do mercury impacts change with aging?*

9. *What evidence is there, if any, that mercury changes the rate or severity of degenerative neurological conditions such as Alzheimers, ALS, etc.?*

10. *What is the most important source of mercury in humans? How would you characterize the levels of mercury, if any, in piscivorous wildlife, such as ducks, loons, and otters? What effect, if any, do dental fillings have on human mercury body burden? How would you characterize the risk of methyl mercury exposure from eating wild fish alone compared to the total mercury risk in an Aboriginal population that also eats ducks, otters, store fish, and has dental fillings?*

11. *What is the Health Canada – World Health Organization recommended fish mercury content limit (measured in parts per million – ppm) for subsistence eaters? What is the mercury limit measured in ppm for legal possession of lake fish meant for sale in Ontario?*

12. *In general, what is a reference dose? Compare the Canadian reference dose for preventing fetal neurotoxicity and developmental impacts with the reference dose adopted by the Environmental Protection Agency in the United States ("USEPA")? What caveats, if any, come with using the USEPA reference dose? Which of the two reference doses, in your professional opinion, is more appropriate and safe to use (1) for the general population, and (2) at Grassy Narrows, and why?*

13. *How does the USEPA reference dose, if at all, account for bio-concentration across the placenta? If it does not account for bio-concentration, how would it need to be modified in order to do so? How does the Canadian reference dose, if at all, account for bio-concentration across the placenta?*

14. *What are the health benefits, if any, of eating fish? What are the health benefits, if any, of the practice of fishing?*

15. *If there are health benefits to eating fish what, in your professional opinion and in the scientific literature of which you are aware, should be done with respect to practices that lead to the bio-accumulation of mercury in fish? How would this principle apply at Grassy Narrows?*

16. *How would you characterize the appropriateness of the health guidance contained in the Ontario Guide for Sport Fish Eaters for indigenous communities who eat fish? Which reference dose is used in developing the Guide?*

17. *Compare with the general population, the level of sensitivity of those who already have experienced elevated mercury exposure, or show symptoms of mercury poisoning, upon further exposure? Comment on the appropriateness of intake guidelines designed for the general population when applied to people exhibiting symptoms consistent with mercury poisoning?*

Grassy Narrows

18. *For document B listed above, and if not already addressed in response to question 1, please indicate the following:*

    a. *What role, if any, did you play in the preparation of document B?*
    b. *Are the findings and conclusions contained in document B still valid today? If not, indicate what material changes have occurred since the release of document B that would cause the need for significant revisions in its findings and conclusions?*
    c. *What would be the revised findings and conclusions, if any?*

19. *If not otherwise answered in response to question 1, above, please indicate if the statements are accurate that are contained in the first six pages of the September 2014 supplementary submission listed in item A that are attributed to your document B report?*

20. *Are you aware of a more thorough long-term study than that of Dr. Harada and his colleagues from Japan (including Takaoka and Fujino, et al.), on the issue of mercury exposure and effects at Grassy Narrows?*

21. *What risks, if any, do current mercury levels in pike and walleye present to the people of Grassy Narrows who eat fish caught from local waters?*

22. What risk is there, if any, to the health of people at Grassy Narrows who eat fish caught from local waters if mercury levels were to increase? How low an increase in fish mercury level would pose a health risk, if any?

ORGANIZATION OF EXPERT REPORT

The Expert Report is organized into two parts. Part 1 provides short summary answers to the questions listed above.

Part 2 updates the review of the scientific literature presented in the document entitled *Literature Review: The Impact of Mercury on Human Health* prepared by Dr. H.M. Chan and myself for the Mercury Disability Board in 2009, and in 2010 with a review of Dr. Harada's studies (Document B). Taken together, these provide the greater context and scientific background for the summary answers provided in Part 1.

PART 1

SUMMARY ANSWERS TO QUESTIONS

Question 1:

1. For the documents referred to below, please indicate if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto.

> ***A. The Grassy Narrows-Earthroots request, dated January 2014, of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May, July, September and November 2014 insofar as they relate to your area of expertise and the subject matter for your report.***

Answer to Question 1A: The information contained in these documents as concerns my expertise on mercury exposure and human health are accurate, with the following details

- **[IEA request, supplemental information, September, 2014 p. 3]** I verified this information with a colleague at the Minamata Institute, Dr. Mineshi Sakamoto, who informed me that the diagnostic criteria for Minamata disease have not changed. These

are the same diagnostic criteria that Dr. Harada used in Grassy Narrows. In Japan, a Law Concerning Special Measures to Provide Relief to Minamata Disease Victims, passed in 2009 was enacted in April, 2010[1]. On May 1, 2010, then Prime Minister Hatoyama attended and gave prayers at the Memorial Service for the Victims of Minamata Disease and was the first prime minister to do so. On the same day, the acceptance of applications for relief started, and eligible persons began to receive a lump sum payment in October 2010. By 2012, there were 48,327 applications for lump-sum payment and 16,824 applications for Minamata Disease Victims' Passbook. It is noteworthy that as early as 1977, the Japanese Ministry of the Environment initiated dredging because " even though the discharge of the methylmercury compound was stopped, the residual presence of mercury in the substratum of nearby waters could still cause the contamination of water and marine lives, making it necessary to remove the contaminated base sediment.

- **[IEA request, supplemental information, September, 2014 p. 8]** The information written up in the Toronto Star (2003) was, in part, in error. I verified this information with Dr. Laurie Chan. While Dr, Chan did express his alarm at the high prevalence of persons still suffering from neurological symptoms after 30 years, he did not head a Health Canada financed study of neurological effects in Grassy Narrows. He did examine mercury in fish, fish consumption patterns and human exposure in Grassy Narrows[2].

- **[IEA request. Supplemental information, November, 2014]** While the psychological, social and economic impacts, cited in the Donnan 1986 report, are accurate, they do not do justice to the overall impact of mercury contamination and the ensuing reduced consumption of fish on the physical and mental health and well-being within the Grassy Narrow community.

- **[IEA request. Supplemental information, November, 2014; p. 13]** more precisely: the value for fish advisories at 0.049 µg/g is the EPA screening value for fish was derived specifically for subsistence fishers[3]. (see answer to Question 11)

- **[IEA request. Supplemental information, November, 2014; p. 13]** more precisely: as indicated in the text, the 0.2 µ/g wet weight was a recommendation made by the Medical Services Branch of Health and Welfare Canada for Grassy Narrows and White Dog in 1979.

- **[IEA request. Supplemental information, November, 2014; p. 15]** I would rephrase the term 'the scientific literature recommends' in the following terms: There is scientific

[1] Japan Ministry of the Environment (2013)

[2] Chan (2005)

[3] EPA Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories Volume 2 Risk Assessment and Fish Consumption Limits Third Edition, p. 1-6 (2000)

evidence to support that the EPA RfD, based on cord blood, may be too high since cord blood contains 60-70% more mercury than maternal blood, and approximately 100% higher for the upper 5% and recent studies have observed neurotoxic effects in children at these levels of prenatal exposure (see question 7 and Part 2; section 4).

B. Literature Review of the Mercury Disability Board, dated September 2010. This document (consisting of two reviews) is referred to in the September 2014 submission

Answer to Question 1B:

I was co-author of these reports and the information contained in these reports is still timely. Studies since that time further support and confirm the conclusions of these reports.

Question 1.1: For the documents referred to below, please indicate your views on them to the extent they relate to the subject matter of your expert report and are within your area of expertise:

C. The article by Harada, et al. entitled "Mercury Poisoning in First Nations Groups in Ontario: 35 Years of Minamata Disease in Canada" (translated from the Japanese version published in the Journal of Minamata Studies in 2011).

Answer to question 1.1 C.

In the article, Dr. Harada describes his experience over the past 35 years in the diagnosis of Minamata Disease in Grassy Narrows and White Dog. Dr. Harada was a clinical neurologist, with world-renowned expertise on Minamata Disease, who began examining patients with Minamata disease in 1961 and was the first to describe Foetal Minamata Disease from prenatal mercury exposure.

He relates in this article that since 1975 he has examined persons from Grassy Narrows and White Dog for signs and symptoms of Monamata Disease. Over the years, he has diagnosed many cases of Minamata Disease in these two communities. The studies up to 2004 are reviewed in our report to the Mecury Disability Board (see Document B).

In 2010, he lead a team, which included 5 neurologists/psychiatrists and internal medicine specialists in neurology. In Grassy Narrows, they examined 73 persons above the age of 20 years on the basis of the diagnostic criteria applied in Japan since 1975 for Minamata Disease. The team identified 30 persons with Minamata Disease and a further 12 persons with "suspected Miniamata Disease", within which there were 5 cases reminiscent of Minimata developmental disorders from fetal exposure. Dr. Harada notes in this report that "fetal influence remains to be

studied … there is no plan of investigation as of now."

The article reflects a great degree of thoughtfulness and care on the part of the physicians involved and, as Dr. Harada so aptly stated, ".. the undoubtable fact that Minamata Disease occurred in the corresponding districts in Canada, based on [their] long term investigation result."

D. The article by Takaoka, et al. entitled "Signs and Symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" published in the journal Science of the Total Environment in 2014.

Answer to question 1.1D.

In this article Takaoka and co-authors describe a comparison of signs and symptoms of 80 residents from Grassy Narrows above the age of 16 years with 88 mercury exposed Japanese residents and 164 Japanese non-exposed control residents. The group from Grassy Narrows was divided into 2 groups according to age: older from 45 years old to 76 years old and younger (less than 45 years of age). The age of the two Japanese groups were similar to the older Grassy Narrows group. Their findings were:

- Although the Japanese exposed group reported more subjective symptoms, the more specific mercury related complaints were similar for the Japanese exposed and the Grassy Narrows older group.

- Neurological findings and quantitative sensory measurements were similar in the Grassy Narrows Older and Japanese Exposed groups than in the Japanese Control group.

- The results for the younger Grassy Narrows group fell between those of the Grassy Narrow Older and Japanese Control groups.

- The authors mention the limitations of such a comparison due primarily to different living conditions and cultures, but emphasize the diagnostic validity of the examination.

- The authors conclude that the data collected from methylmercury-exposed indigenous residents of Grassy Narrows suggest that they were poisoned by methylmercury. The health abnormalities also appear to exist in a milder form in the younger generations from Grassy Narrows.

The findings of this study are consistent with the scientific literature on mercury poisoning. In the absence of an epidemiologic study on neurotoxic effects of mercury exposure in Grassy Narrows, the study presents an innovative way of examining similarities and differences in signs and symptoms in communities who have been exposed to mercury. Ideally, it would have been

useful to examine the signs and symptoms in Grassy Narrow residents with respect to past and present exposure and use a local reference group.

Question 2: Regarding the subject of mercury and human health:

a. Is mercury toxic to humans? If so, on the scale of toxic substances in the environment, where does mercury rank in terms of overall toxicity risk to humans?

Answer to Question 2a

Mercury is definitely toxic to humans. Every few years, the United States Agency for Toxic Substances establishes a Priority List of Hazardous Substances, which includes substances that have been determined to be of greatest public health concern to persons at or near National Priority List sites[1][2]. While this list considers aspects other than toxicity, it includes a measure of toxicity. The 2013, Registry[3] gives mercury the highest attributable toxicity points, at the same levels as arsenic and polychlorinated biphenyls (PCBs) and ranks mercury ranks third (after arsenic and lead) on the overall priority scoring list of 785 hazardous substances. It is noteworthy that mercury has held this ranking since 1991, when the first list was established.

b. If so, what are the clinical human health impacts of mercury?

The most severe clinical impacts of fetal and adult exposure to methyl mercury are the neurodegenerative diseases: Foetal Minamata Disease and Minamata Disease, respectively.

Clinical effects in adults : Gait disturbance, loss of balance, speech disturbance constriction of visual fields, sensory disturbances (numbness, loss of feeling or tingling in extremities and around the mouth), hearing disturbances, muscle weakness, muscle cramps

Clinical effects of in utero exposure : severe cerebral palsy-like symptoms, even when their mothers have mild or no manifestation of the poisoning: mental retardation, cerebellar ataxia (coordination and balance problems), primitive reflexes (present in infants, which should disappear in adulthood), dysarthria (muscle speech disorders), and hyperkinesia (uncontrolled muscular movements).

c. Does exposure to mercury increase the risk of other health problems developing and, if so, identify those other health problems?

[1] Agency for Toxic Substances Registry (http://www.atsdr.cdc.gov/spl/)
[2] It should be noted that this priority list is not a list of "most toxic" substances, but rather a prioritization of substances based on a combination of their frequency, toxicity, and potential for human exposure at NPL sites ((http://www.atsdr.cdc.gov/spl/))
[3] Agency for Toxic Substances Registry. Support Document to the 2013 list of hazardous substances that will be the subject of toxicological profiles.

Mercury has been shown to increase the risk for learning disabilities in children and, in adults, the risk for cardiovascular disorders, such as myocardial infarction and hypertension. There is some evidence of an association between mercury exposure and metabolic syndrome, diabetes and autoimmune disorders, but more studies are required to confirm or not these associations (see Part 2, section 1)

Question 3: At what levels of exposure to mercury have adverse clinical health impacts on adults been documented in the scientific literature? What are the reported adverse clinical health effects in adults at these levels?

Answer to Question 3:

For clinical neurological effects in adults, case reports of moderate to severe neurological symptoms in patients with blood mercury concentrations from 12 – 38 µg/L[1,2].

It should be noted that, for adults, it is difficult to establish a level of exposure since mercury-related subtle neurological alterations may have existed since conception and the biomarkers of mercury exposure (hair and blood) only represent recent exposure. Thus, adults who have been prenatally exposed to mercury, with continued exposure through childhood and early adulthood, may suffer clinical effects that are not related to their current mercury exposure, but to their past exposure. Furthermore, the large majority of studies on adults include persons who eat marine fish, which have considerably higher concentrations of beneficial nutrients such as omega-3 fatty acids and selenium, compared to freshwater fish.

Question 4: Does exposure to mercury effect the development of fetuses and children and, if so, what are the effects, and for what duration of time, if any, will those effects persist? At what exposure levels have these developmental effects been documented in the scientific literature?

Answer to Question 4:

There is a very substantial scientific literature showing prenatal and early childhood exposure to mercury is associated with a decrease in children's intellectual capacities. This has been confirmed in animal studies and in brain imaging and electrophysiological examinations (see Part 2; sections 5 and 6).

[1] Silbernagel et al. (2011)
[2] Groth (2008)

Follow-up studies of mercury-exposed children indicate that these deficits persist over time. For example, a study of Canadian Inuit children at 8 years of age, exposed prenatally to mercury, showed that 17.2% of the children whose cord blood mercury was above 7.5µg/L were below the clinical cut-off for learning disabilities compared to 4.3% for the others[1].

A 22-year follow-up study of children of mothers with high mercury exposure[2] shows that there are still deficits in major domains of brain function as well as general intelligence in relation to their cord blood mercury concentrations; the geometric mean of their current blood mercury concentrations was 2.53µg/L and hair mercury 0.68µg/g.

The lowest reference dose for the protection of foetus and children is the US EPA reference dose (5.8 µg/L blood mercury; 1 µg/g hair mercury), which includes a tenfold uncertainty factor[3]. However, since the mercury in the cord blood is higher than in mother's blood, it may be too high (see part 2, section 4).

Question 5: Are there sub-clinical effects:

a. *In a community where mercury-related neurologic clinical disorders are present, could there be other persons with sub-clinical signs and symptoms?*
b. *Nature of these effects at each exposure level that have been documented in the scientific literature; and*
c. *Developmental effects of mercury, if any, in children in families with low socio-economic status based on such factors as education, income, etc.?*

Answer to Question 5a:

Clinical manifestations of mercury poisoning constitute the tip of the iceberg with respect to the harmful health effects of mercury exposure. In a contaminated environment, for every person with clinical manifestations, there are many more with sub-clinical signs and symptoms and even more with symptoms of decreased well-being, which affect a person's physical, mental and social capacities.

Answer to Question 5b:

In adults, the tip of the iceberg is composed of people with the most severe classical symptoms of mercury poisoning (described in answer to question 2b), a higher number of mercury-exposed persons present signs and symptoms that are less severe, but debilitating, such as poorer cognition, motor deficits, vision problems and cataracts. Cognitive deficits have been

[1] Jacobson et al. (2005)
[2] Debes et al. (2015)
[3] Rice (2004)

observed in freshwater fish-eating communities with hair mercury concentrations that ranged from 0.56 to 13.6 µg/g, with half of the participants having levels below 6 µg/g.

For cardiovascular effects, an analysis of existing studies by an expert committee indicate a twofold increased risk for myocardial infarction at equivalent hair concentrations less than 1.66µg/L[1] (see Part 2, section 1)

In children, the most severe classical symptoms of mercury exposure in their development years is described in question 2b. Many more children are exposed to lesser concentrations.

There is consensus on the fact that mercury exposure is associated with delayed learning, shortened attention span, memory deficits, delayed language acquisition, poorer motor control or coordination (see part 2, sections 5 and 6)

Even at very low concentrations of prenatal and early childhood exposures (maternal mean hair mercury 0. 0.53 (range 0–2.3) µg/g)[2], some of these effects are present in the developing child and the frequency and severity of these problems increases with the exposure dose.

In the study of Inuit children mentioned above, mothers' hair mercury at birth ranged from 1.4µg/g – 15 µg/g.

Electrophysiological and neuro-imaging techniques have confirmed altered brain activity in children with prenatal exposure to mercury

Answer to Question 5c.

In addition to mercury exposure, children's development can be affected by other factors, such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle, little access to health care, poor schooling, minimal parental stimulation (see Part 2, section 6).

Developmental mercury exposure can compound the effects of these conditions, resulting in, for example, a larger percentage of children with learning disabilities (see Part 2, Section 6, Figures 4,5 and 6)) .

Question 6: What are the sub-clinical population level effects, if any, of exposure to mercury? Comment on the nature and severity of the effect of these impacts at a community level? What are the levels of mercury exposure documented in the scientific literature at which these effects can occur?

[1] Guallar et al. (2002)
[2] Oken et al. (2008)

Answer to Question 6:

For adults, sub-clinical effects include poorer cognitive functions, poorer vision, poor motor function and earlier age-related cataracts. These affect people's capacity to earn their living and carry out daily activities (see part 2 section . Overall the community's capacity to develop is hindered. In some studies, cardiovascular and metabolic changes have been reported in relation to mercury exposure, but results are inconsistent and co-factors, such as nutritional status and lifestyle, may play a role (see Part 2, sections 1 and 2).

For children, even a small decrease in average cognitive function has striking repercussions for the community. For example, an average decrease of 5 IQ points, among exposed children means that, in this community, twice as many children have severe learning difficulties and half as many children are gifted (see Part 2, sections 5 and 6).

When other harmful factors (poor nutrition, lack of stimulation, poor education) are present, the effects of mercury may be greater (see Part 2, section 6). In a study of an Inuit community, an average loos of 4.8 IQ points resulted in over four times more children with learning disability[1]. (Part 2, section 6)

The loss of cognitive function has life-long effects for these children who do less well in school. Educational level is an important determinant of later-life earning capacity and health status.

Question 7: Does mercury bio-concentrate across the placenta and, if so, what is the average concentration factor? What is the concentration factor at the 95th percentile?

Answer to question 7:

Throughout pregnancy, the placenta concentrates methylmercury and blood mercury concentration in the umbilical cord, which nourishes the foetus, is higher than in the mother's blood.

At birth, the average cord mercury blood concentration is almost double that of the mother, while for one in twenty that concentration can be over three and a half times more.(see part 2, section 4)

[1] Jacobson (2015)

Question 8: Is there a delay in the manifestation of health effects following exposure to mercury? How do mercury impacts change with aging?

Answer to Question 8:

Minamata Disease is a progressive disorder and some infants, who had a normal appearance at birth, slowly developed the disease over time.[1]

Studies of persons from the Minamata region show that even those that do not have the diagnosed disease show more signs of aging compared to persons from other regions (see Part 2, section 7 and Figure 6)).

The aging brain is more sensitive to toxic assault and studies of aging fish-eaters exposed to mercury have shown mercury-related progressive visual disorders, even when exposure was reduced, and a higher prevalence of age-related cataracts.(see Part 2, section 7

Question 9: What evidence is there, if any, that mercury changes the rate or severity of degenerative neurological conditions such as Alzheimers, ALS, etc.?

Answer to Question 9:

To my knowledge, there is no evidence of a higher prevalence of Alzheimer's disease or amyotrophic lateral sclerosis (ALS). The features of fœtal Minamata Disease are similar to cerebral palsy. However, because of the pervasive neurologic effects of mercury exposure, there may be misdiagnoses.

Question 10: What is the most important source of mercury in humans? How would you characterize the levels of mercury, if any, in piscivorous wildlife, such as ducks, loons, and otters? What effect, if any, do dental fillings have on human mercury body burden? How would you characterize the risk of methyl mercury exposure from eating wild fish alone compared to the total mercury risk in an Aboriginal population that also eats ducks, otters, store fish, and has dental fillings?

Answer to Question 10:

The most important source of mercury exposure in humans is from the consumption of fish and fish-eating animals (see Part 2, section 8).

Mercury is accumulated and biomagnified through the food chain; the process is initiated through the action of bacteria that transform inorganic mercury, present in the water, to

[1] Maruyama et al, (2012)

methylmercury.

Larger fish eat many small fish, incorporating all of their mercury. Fowl and mammals that eat fish will likewise accumulate mercury in the same way.

At the top of the food chain are humans. The risk depends on the total amount of mercury from each of the foods.

The risk for mercury exposure in Aboriginal populations that eat fish and fish-eating animals has been shown to be considerably higher than in other populations

A study of adult dietary practices among 7 Eeyou Istchee (Cree) communities in the James Bay area showed that blood mercury concentrations 3 – 20 times higher than those reported in the Canadian Health Measures Survey (CHMS) [1], which did not include Aboriginal communities living on reserves. (see Part 2, section 9).

In the study of the Cree community mentioned above, the geometric mean for blood mercury of persons with the highest traditional food intake was 5.3µg/L, for those who consumed the least traditional food, it was 3µg/L,[2] while for the general adult Canadian population, it is approximately 0.8 µg/L[3].

A further source of methylmercury exposure may come from wild rice that grows in sediments that have been contaminated with mercury.

Mercury in dental amalgams is inorganic mercury and it can be measured in blood and urine, but not in hair. In the Canadian Health Measures Survey, blood mercury concentrations increased with the number of dental amalgams. The geometric mean for those with no mercury-based dental amalgams is 0.6 µg/L, while those who have over 26 amalgams, it is 1.24µg/L[4].

Question 11: What is the Health Canada – World Health Organization recommended fish mercury content limit (measured in parts per million – ppm) for subsistence eaters? What is the mercury limit measured in ppm for legal possession of lake fish meant for sale in Ontario?

Answer to Question 11:

---

[1] Johnson-Down et al. (2015)
[2] Johnson-Down et al. (2012)
[3] Lye et al. (2013)
[4] Lye et al. (2013)

There are different types of recommended limits concerning fish consumption: (i) amount of mercury in the fish (expressed in mg/kg, µg/g or ppm); (ii) the amount of mercury considered safe to consume on a daily basis, considering persons' weight (µg/kg/day) over a lifetime; (iii) the average amount of fish that should be eaten (g/day or fish meals/month), based on a risk assessment of risks and benefits. Table 1 contains some of these recommendations from different agencies.

Table 1 Recommendations by different national and international agencies for limits for mercury on fish, mercury consumption and fish consumption

	Canada	Ontario	US-EPA	WHO/FAO
MERCURY IN FISH				
Commercial sale	0.5 ppm[a]			
Fishing for sale				
Recreational			0.4 ppm[c]	
Women of child-bearing age and children under 15		0.26 ppm[b] Do not eat: 0.52 ppm		
Others		0.61 ppm[b] Do not eat: 1.84 ppm		
Subsistence	0.2 ppm[h]		0.049 ppm[c]	
METHYL MERCURY IN THE PLATE				
Intake dose	0.2µg/kg body weight/day[d]		0.1µg/kg body weight/day[e]	0.23µg/kg body weight/day[f]
FISH CONSUMPTION				
General				
1-4 year old	10g/day[g]			
5-11 year old	14g/day[g]			
Adults	22g/day[g]			
Subsistence fishing				
1-4 year old	20g/day[g]			
5-11 year old	33g/day[g]			
Adults	40g/day[g]			

a. There are some exceptions to this for a few marine fish, with higher concentrations
b. These are the values used by the *Ontario Guide for Sport Fisher Eaters (2013-2014)* to provide information on fish consumption for anglers (and their families) who consume

moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch. Specific information is available for each lake.

h. Health and Welfare Canada recommendation for Grassy Narrows and White Dog in 1979.

Question 12: In general, what is a reference dose? Compare the Canadian reference dose for preventing fetal neurotoxicity and developmental impacts with the reference dose adopted by the Environmental Protection Agency in the United States ("USEPA")? What caveats, if any, come with using the USEPA reference dose? Which of the two reference doses, in your professional opinion, is more appropriate and safe to use (1) for the general population, and (2) at Grassy Narrows, and why?

Answer to Question 12:

The US-EPA uses the term Reference Dose (RfD), defined as ''an estimate of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects during a lifetime.''[1] Some scientists have raised the issue that this RfD may be too high because it is based on cord blood and does not take into account methylmercury accumulation in the placenta[2].

Canada uses Toxicity Reference Values (TRVs) to derive Total Daily Intake, (TDI) defined as "the maximum amount of a chemical that can be ingested on a daily basis over a lifetime without increased risk of adverse health effects.

As indicated in the table above, for methylmercury, the US-EPA RfD is 0.1µg/kg body weight/day, while the Canadian TDI is 0.2µg/kg body weight/day.

My opinion is that the US-EPA reference offers better protection against the harmful effects of exposure to methyl mercury to all populations. Mercury intake for most of the general Canadian

[1] cited in Rice (2004)
[2] Stern (2005)

population is well below this intake.

In 2003, Chan[1] calculated the intake of mercury in the Grassy Narrow community and estimated mercury intake from fish consumption using the actual values that were measured in fish species from the various lakes and the reported portion size per fish meal.

In Grassy Narrows, in 2003, the average mercury intake over the year was 0.2µg/kg body weight/day, with men having higher average intakes compared to women (0.3 µg/kg body weight/day vs 0.1µg/kg body weight/day). The average intakes included people who don't eat fish; if the analysis was only on fish-eaters, the average mercury intake would have been higher.

By season, the highest mercury intake was by men in summer and spring (3.7 µg/kg body weight/day). Approximately 25% had estimated intakes above the Canadian TDI and 41% were above the US-EPA RfD.

The average mercury intake for Grassy Narrows women in 2003 was above the US-EPA RfD of 0.1 µg/kg body weight/day. It should be noted that this includes all women who were surveyed, including those that don't eat fish.

Cord blood data from Grassy Narrows between 1978 and 1992 shows that they were much higher (see Part 2, section 14a and Figure 8). Today, these persons are between the ages of 23 and 37 years old.

Given the information on estimated methymercury intake from past and present exposures in Grassy Narrows, there are already effects on their health and well-being from mercury exposure and the EPA RfD would be more suitable for the Grassy Narrows population. However, this does not take into account the health, social and economic benefits of fishing and fish consumption.

Question 13: How does the USEPA reference dose, if at all, account for bio-concentration across the placenta? If it does not account for bio-concentration, how would it need to be modified in order to do so? How does the Canadian reference dose, if at all, account for bio-concentration across the placenta?

Answer to Question 13:

The US-EPA reference dose, which is based on cord blood, does not take into account bio-concentration across the placenta. It is based on a cord blood concentration of 58 µ/L and then uses a tenfold security factor to arrive at a cord blood concentration of 5.8µg/L from which mercury intake is derived as 0.1µg/kg body weight/day. Mahaffey, who was one of the

[1] Chan (2005)

committee members who set the EPA RfD suggests that it should be based on a value of 3.5 µg/L to take into account bioconcentration[1]. The relation between maternal mercury intake and cord blood is not necessarily linear[2] and what one can say at this point is that it would be lower than 0.1µg/kg body weight/day.

The Canadian Total Daily Intake is based on used maternal hair at birth[3] and did not take into account placental bioconcentration and thus did not account for the fact that hair mercury concentrations decrease over pregnancy (see Part 2; figure 2).

Question 14: What are the health benefits, if any, of eating fish? What are the health benefits, if any, of the practice of fishing?

Answer to Question 14:

Fish is a highly nutritious food, providing a wide variety of nutrients, including omega-3 fatty acids (see Part 2, section 11).

In utero and throughout lifespan, omega-3 fatty acids are likewise positive physical and mental health outcomes, including children's neurodevelopment,
vision, blood pressure, cardiac function, vascular reactivity and lipids.

Studies of children exposed to mercury through fish consumption show the negative effects of mercury exposure and the positive effects of omega-3 fatty acids on neurodevelopment. Studies of adults, as well, have shown the opposing effects of mercury and omega-3 fatty acids and visual function, as well as for the risk of myocardial infarction (Part 2, section 11, Figure 7)

The US-EPA advisory for subsistence fishing was developed in collaboration with representatives from Native American tribes. It indicates : "EPA recognizes, however, that Native American subsistence fishers are a unique subsistence fisher population that needs to be considered separately. For Native American subsistence fishers, eating fish is not simply a dietary choice that can be completely eliminated if chemical contamination reaches unacceptable levels; rather eating fish is an integral part of their lifestyle and culture. This traditional lifestyle is a living religion that includes values about environmental responsibility and community health as taught by elders and tribal religious leaders. Therefore, methods for balancing benefits and risks from eating contaminated fish must be evaluated differently than for the general fisher population"[4]."

[1] Mahaffey (2009)
[2] Stern (2003)
[3] Legrand et al (2010)
[4] US Environmental Protection Agency *Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories Volume 2 Risk Assessment and Fish Consumption Limits Third Edition (2000) p. 16*

Question 15: If there are health benefits to eating fish what, in your professional opinion and in the scientific literature of which you are aware, should be done with respect to practices that lead to the bio-accumulation of mercury in fish? How would this principle apply at Grassy Narrows?

Answer to Question 15:

In my professional opinion, based on the existing scientific literature, fish-eating practices should seek to maximize the nutritional benefits from fish consumption and minimize the toxic risk from mercury and other contaminants.

The Grassy Narrows community has been exposed to high concentrations mercury in fish for many years and individuals and the community are suffering the effects. **It would only add toxic insult to toxic injury to further expose this population to mercury**

While the community needs the nutrition from the fish, their intake of mercury needs to be minimal. To achieve this there needs to be a comprehensive plan:

- to reduce mercury at the source in the lake sediments;
- to never increase the mercury load in this environment;
- to eat more fish with little mercury;
- to initiate schooling and health programs to address the issue of mercury poisoning in this community.

Question 16: How would you characterize the appropriateness of the health guidance contained in the Ontario Guide for Sport Fish Eaters for indigenous communities who eat fish? Which reference dose is used in developing the Guide?

Answer to Question 16:

The Ontario Guide for Sport Fish Eaters is designed for "anglers (and their families) who consume moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch." The guide note that the advisory is based on the Canadian TDI. Their fish advisory recommends that "for women of child-bearing age and children under 15 years old, restrictions on consuming sport fish containing mercury begin at levels of 0.26 parts per million. Complete restriction (i.e., do not eat) is advised for levels above 0.52 parts per million. For the general population, consumption restrictions begin at levels above 0.61 parts per million. Complete restriction is advised for levels above 1.84 parts per million."[1]

[1] Ontario Ministry of the Environment. 2013-2014 Guide to Eating Ontario Sport Fish, p. 16,

The guide clearly indicates that it is not for heavy fish eaters. In Grassy Narrows, using the 2003 information on fish consumption from Chan, approximately 16% of persons eat more than 9 fish meals/month, and the average mercury content for several of the fish species in many of the lakes is above 0.52 ppm.

Question 17: Compare with the general population, the level of sensitivity of those who already have experienced elevated mercury exposure, or show symptoms of mercury poisoning, upon further exposure? Comment on the appropriateness of intake guidelines designed for the general population when applied to people exhibiting symptoms consistent with mercury poisoning?

Answer to Question 17:

There is ample evidence from animal and human studies that mercury modifies normal functioning of many systems, and in particular, the nervous system. While some of these changes result in symptoms and signs of damage, many remain undetectable because of the body's capacity to adapt. There is, however, a limit to this physiological adaptation and further exposure will build on the damage already present.

The guidelines for mercury intake refer to "over a lifetime". If exposures have been higher in the past than at present, the intake guidelines do not apply since over the lifespan, one's intake will be higher than those recommended by the guidelines.

Grassy Narrows

Question 18: For document B listed above, and if not already addressed in response to question 1, please indicate the following:

- ***a. What role, if any, did you play in the preparation of document B?***
- ***b. Are the findings and conclusions contained in document B still valid today? If not, indicate what material changes have occurred since the release of document B that would cause the need for significant revisions in its findings and conclusions?***
- ***c. What would be the revised findings and conclusions, if any?***

Answer to Question !8a:

I prepared document B in collaboration with Dr. Laurie Chan, Professor and holder of the Canada Research Chair in Toxicology and Environmental Health.

Answer to Question !8b:

The findings and conclusion of document B, which was submitted to the Mercury Disability Board in 2010, are still valid today. Since that time the science of mercury exposure and its effects on human health has continued to advance substantially and Part 2 of the present document updates the scientific evidence since that time. Studies published since 2010 on the effects of mercury on health and well-being, confirm the conclusions contained in Document B.

Answer to Question !8c:

The more recent studies indicate effects of mercury exposure are present at lower levels than previously thought and that they are long-lasting.

Question 19: If not otherwise answered in response to question 1, above, please indicate if the statements are accurate that are contained in the first six pages of the September 2014 supplementary submission listed in item A that are attributed to your document B report?

Answer to Question 19:

The statements are accurate and the scientific literature of the past 5 years provide strong confirmation. One further update : The law Concerning Special Measures to Provide Relief to Minamata Disease Victims, passed in 2009 was enacted in April, 2010 (see question 1 above).

Question 20: Are you aware of a more thorough long-term study than that of Dr. Harada and his colleagues from Japan (including Takaoka and Fujino, et al.), on the issue of mercury exposure and effects at Grassy Narrows?

Answer to Question 20:

Dr. Harada was a clinical neurologist, with world-renowned expertise on Minamata Disease, who began examining patients with Minamata Disease in 1961. He carried out a most thorough study of clinical manifestations of Minamata Disease in Grassy Narrows. No other group of scientists have carried extensive health studies with this community, although, as we indicated in the MDB report and Dr. Harada mentions in his 2011 report, there is a need for studies on the long-term effects of foetal exposure and the overall impact of mercury exposure on the physical and mental well-being of this community.

Question 21: What risks, if any, do current mercury levels in pike and walleye present to the people of Grassy Narrows who eat fish caught from local waters?

Answer to Question 21:

According to the 2005 report by Chan[1], the average mercury concentration in walleye in the lakes that are around Grassy Narrows (Ball Lake, Garden Lake and Indian Lake) are above almost all fish advisories guidelines for consumption. They are between twelve to twenty times higher than the US-EPA screening value for subsistence fish-eating. Northern Pike from these lakes, which are twelve to eighteen times higher than the screening value. Using the Ontario Fish advisories, all of the walleye and northern pike from these lakes are above the 'do not eat' concentration for women of child-bearing age and children (0.52 µg/g), while for the others, there would be restrictions for Ball and Indian Lake since the average mercury concentration in fish is above 0.62 µg/g).

Historical data from the English-Wabigoon River system from 1975 onwards show that there were much higher exposures in the past. While these high concentrations for walleye and northern pike declined rapidly from 1975 to 1985, the decline was much less and often stable until 2010[2].

When estimating the risk for mercury poisoning in Grassy Narrows, it is necessary to take into account past and present exposures, including prenatal exposure. Even without actual data, it is clear that the risk for mercury poisoning is very high for walleye and northern pike fish-eaters.

It should also be mentioned that particularly for *in utero* exposures, immediately after ingestion of the fish, there would be a very large peak of mercury exposure at a critical moments in fetal development. Prenatal effects may differ depending upon the moment of this peak exposure during foetal development.

Question 22: What risk is there, if any, to the health of people at Grassy Narrows who eat fish caught from local waters if mercury levels were to increase?

Answer to Question 22:

There is no question that the mercury already present in the Grassy Narrow area poses important risks to health and well-being to the community and that any further addition of mercury would increase that risk. It would, indeed be adding insult to injury. In my opinion, based on the scientific literature and Dr. Harada's work, it would be shameless, and I would call it irresponsible, to add more mercury to this mercury-laden environment. The health and well being of this community has already been harmed not only through mercury poisoning of those

[1] Chan (2005)
[2] Neff et al. (2012)

who continue to eat fish, but also and by depriving important nutrients to those who reduced their fish consumption because of the mercury.

PART 2

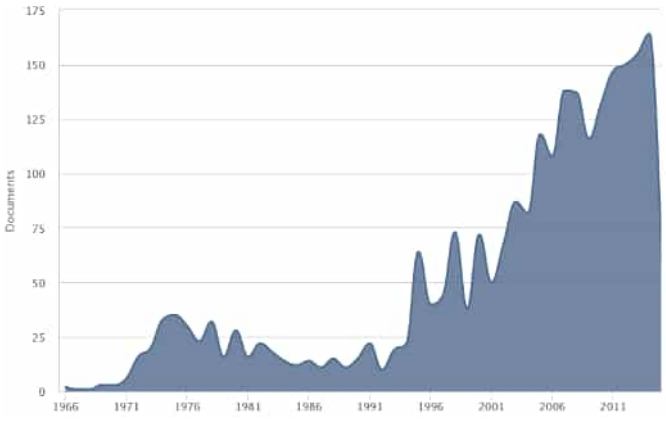
OVERVIEW

"At first, methyl mercury research was impaired by inappropriate attention to narrow case definitions and uncertain chemical speciation. It also ignored the link between ecotoxicity and human toxicity. As a result, serious delays affected the recognition of methyl mercury as a cause of serious human poisonings in Minamata, Japan. Developmental neurotoxicity was first reported in 1952, but despite accumulating evidence, the vulnerability of the developing nervous system was not taken into account in risk assessment internationally until approximately 50 years later. Imprecision in exposure assessment and other forms of uncertainty tended to cause an underestimation of methyl mercury toxicity and repeatedly led to calls for more research rather than prevention."

Grandjean et al, 2010

This review on general mercury and health facts sought to provide the most up-to-date information on mercury and human health, building on the information contained in the document entitled *Literature Review: The Impact of Mercury on Human Health* prepared by Dr. H.M. Chan and myself for the Mercury Disability Board in 2009, updated in 2010 with a review of Dr. Harada's studies. The two documents provide the scientific background for the answers to the questions above. Since 2010, over 800 articles have been published on methyl mercury and fish, with half in the medical domain. Figure 1 shows the evolution of articles on methyl mercury and fish since 1966. Approximately half of these are on health issues.

Figure 1 Evolution of scientific articles on methyl mercury and fish since 1966



The literature review, here, is not exhaustive and serves to respond to the questions that were posed. Relevant published scientific reviews and studies, since we wrote the report for the Mercury Disability Board in 2010 were identified, and where, possible, an emphasis placed on

those that examined methyl mercury exposure and health effects in Canadian First Nation and Inuit communities.

The studies of the past years, reviewed here, support the following conclusions:

- There is no doubt that at the levels of exposure experienced in Grassy Narrows, the community has suffered and continues to suffer from mercury poisoning, individually and collectively.
- The scientific literature continues to provide evidence for Dr. Masazumi Harada and colleagues' clinical findings, reviewed by Chan and Mergler for the MDB[1] on the similarities between the neurologic signs and symptoms of persons from Grassy Narrows and White Dog and Minimata Disease in Japan. Using the diagnostic criteria for Minamata Disease, in Harada's 2010 he diagnosed Minamata Disease in 30 people from Grassy Narrows and 12 persons with 'suspected MInimata Disease.' (see question 1 C).
- The reduction of consumption of local fish and wildlife resulting from mercury pollution of the area deprived the people of Grassy Narrows of healthful nutrients, which have been shown to be beneficial for a large number of physiological functions and to be preventive for many and diseases.
- It is surprising that although the Japanese neurologists have identified many cases of Minamata Disease in Grassy Narrows and many persons have illnesses that have been associated with mercury intoxication, there has never been a scientifically sound epidemiologic study of the impact of pre and post natal mercury exposure on the health and well-being of this community.
- Any increase of exposure to this already 'sensitive' community to mercury contamination from sources, such as mining, logging and reservoirs, would further compound the harm to the health and well-being of the present and future generations.

1. Mercury is highly toxic to human health. Impacts include foetal and child development, neurological disorders and cardiovascular changes.

The effects of mercury from fish consumption on the nervous system has been extensively studied since the Minamata disaster and there is consensus on mercury neurotoxicity and its harmful neurologic effects during foetal and child development and in adults. Epidemiologic studies of exposed populations show **increased risk for neurodevelopmental deficits, loss of cognitive and motor functions and visual deficits[2]. C**hanges in brain functioning in methyl mercury-exposed persons have been confirmed in electrophysiological[3] and brain imaging[4]

[1] Chan and Mergler (2010)
[2] Grandjean et al. (2010)
[3] Ethier et al, (2012)
[4] White et al. (2011)

studies. Experimental studies with mercury-exposed animals provide extensive information on the mechanisms that underlie mercury toxicity[1].

More recently, the possible effects of mercury on other health endpoints have been examined. In 2011, the Environmental Protection Agency of the United States convened a workshop of experts on methylmercury exposure and cardiovascular endpoints[2]. The authors concluded that there was strong evidence for the relation between biomarkers of mercury exposure, measures in toenails or hair and **myocardial infarction (MI). It is noteworthy that the range of the equivalent hair mercury exposure of the studies reviewed by this committee was from 0.34µg/g to 1.66µg/g[3].** Among the studies, upon which their conclusions were based, was an international study that showed a doubling of the risk for a first myocardial infarctus for men in the highest quintile of hair mercury.

In addition, several studies have shown associations between biomarkers of methyl mercury exposure and other **cardiovascular disorders,** including hypertension and changes in heart rate variability profiles[4]. In a study of Cree adults[5], the authors observed a positive association between altered heart rate variability parameters and blood mercury, after considering fish nutrients (omega-3 fatty acids and selenium) and other contaminants (lead and polychlorinated biphenyls) that are also present in the traditional diet of this population.

There is some evidence that mercury exposure increases the risk for **Type II diabetes**, but it is inconsistent. A recent 18-year follow-up study[6] of 3875 young United States' adults (20-32 years old), free of diabetes at the onset of the study, showed that those with the highest mercury exposure (equivalent of 1.2 – 1.5 µg/g hair mercury) had an elevated risk for diabetes compared to those with the lowest exposure, while another follow-up study of 2 cohorts did not show an association of incident cases of Type 2 diabetes and toenail mercury. concentrations[7]. An analysis of data from the Korean National Health and Nutrition Examination Survey showed and increased risk for **metabolic syndrome** in men with respect to blood mercury, but not in women[8].

A recent study used the data from the United States' National Health and Nutrition Evaluation on 1352 women of reproductive age women (16 – 49 years) to examine biomarkers of the immune system. Low levels of blood and hair mercury, generally considered safe, were

[8] Chung et al, (2014)

associated with subclinical **autoimmunity** among reproductive-age females.[1]. The authors put forward that methylmercury exposure may be relevant to future autoimmune disease risk.

2. Adults can be impacted at levels well below the old threshold level for risk of 50 µg/g in hair.

With the increasing information from research on risks of methyl mercury exposure and the evolution in our understanding of how subtle functional alterations in many individuals can translate into important risks for a community (see Part 2, section 5), regulatory agencies continue to revise recommended threshold levels for risk.

In Canada in the 1970's, the agency that later became the First Nation and Inuit Health Branch of Health Canada considered blood mercury levels below 20 µg/L (or 6 mg/kg in hair) as being "acceptable" and levels greater than 100 µg/L in blood (or 30 mg/kg in hair) as "at risk" based on the knowledge at that time and the unusually high mercury concentrations observed in Grassy Narrows and Whitedog[2]. Today, Health Canada provides different threshold levels for risk depending on age and sex. Legrand and co-authors[3] summarized existing Health Canada methyl mercury blood guidance values for the general population and expanded them to include a harmonized provisional interim blood guidance value. The threshold action levels for pregnant women, women from birth to 49 years and men less than 18 years was reduced but those for women above 50 years and men over 18 years, they are the same as in the 1970s. The table below is adapted from the table in the article by Legrand et al. in 2010 entitled:

Table 2 Overview of Health Canada Existing and Harmonized Blood Methylmercury Guidance Values

	Blood mercury threshold action levels			
	1	2	3	4
• pregnant women • women from birth to 49 years • men less than 18 years	less than 8 µg/L	8 – 40 µg/L	above 40 µg/L	
• women above 50 years • men above 18	less than 20 µg/L	20 -100 µg/L		
• women and men all ages				above 100µg/L

[1] Somers et al. (2015)
[2] Legrand et al. (2010)
[3] Legrand et al. (2010)

Action levels :

1. No follow-up required
2. Repeat blood/hair test in 6 months ; provide dietary advice
3. Repeat blood/hair test immediately ; schedule an appointment with a public health professional to review exposure history to identify sources of mercury exposure; provide dietary advice;
4. Repeat blood/hair test immediately ; schedule an appointment with a public health professional to review exposure history to identify sources of mercury exposure ; provide dietary advice ; refer study participant to a physician or medical toxicologist for assessment and follow-up in terms of checking basic neurological signs and symptoms and making a decision concerning appropriateness of any therapeutic intervention

Other regulatory agencies have one reference dose for all, based on the studies of prenatal exposure and effects. The US-EPA reference dose for oral exposure to methyl mercury is 0.1µg/kg body weight/day, which corresponds to mercury concentration of 5.8 µg/L (1 µg/g hair mercury)[1]. The Joint Expert Committee on Food Additives and Contaminants (JECFA) of the Food and Agriculture Organization (FAO) and the World Health Organization (WHO) proposed 1.6µ/kg body weight/ week (0.23µg/kg body weight/day)[2]. However, a recent review of the JEFCA guidelines by the European Food Safety Authority (EFSA)[3], published in 2012 and based on European data for fish consumption, proposed that the tolerable weekly intake be reduced to 1.3 µg/kg/week (0.19µg/kg body weight/day).

It is difficult to propose a threshold value for adults since few studies have focused on adult men and non-pregnant women since the developing foetus and child are more vulnerable to toxics and mercury is actively transported from the mother to the foetus. Moreover, the results on the studies on adults are inconsistent, probably due to the fact that the adults under study have different life histories (including prenatal exposure), life styles and nutrition (including difference in consumption of marine and fresh-water fish). The Health Canada guidelines in the Table above consider blood mercury of 20µg/L, which is approximately 10µg/g hair mercury.

A study of Taiwanese 240 adults (36 – 70 years old), who had lived in the region of a chloralkali plant that had been in operation between 1942 and 1985, was undertaken in 2005[4]. Mean total blood mercury was 17.3 ± 10.9 µg/L, with 90% methyl mercury. Comparison of those in the 75th percentile (greater or equal to 19.2µg/L; mean 27.1 ± 10.9) to the others (mean 11.6 ± 4.7 µg/L) showed higher abnormality rates for tests of remote memory, mental manipulation, orientation and verbal fluency, but not for tests covering recent memory, attention, abstract thinking, language and drawing. The authors indicate that they do not have information on historic

exposures.

3. Fetuses and children can be impacted at far lower levels than adults.

There is now a very large number of studies on prenatal exposure to mercury and adverse health effects, most notably on children's neurodevelopment. In their review of the literature, EFSA[1] identified 34 articles of children's neurodevelopment in relation to prenatal exposure since 2003; the results of these studies motivate their recommendation to reduce the threshold for intake from 1.6µ/kg body weight/week to 1.3 µ/kg body weight/week, which would correspond to a decrease in blood mercury from 12 µg/L to 9.6 µg/L. As noted above, Health Canada considers a guidance level for blood mercury of 8 µg/L (hair mercury 2µg/g considering a ratio of 250:1) for pregnant women and women of reproductive age.

The lowest reference dose for the protection of foetus and children is the US EPA reference dose, which was based on three cohort studies of fish-eating populations[2]. It was derived by taking the lower limit of the benchmark dose[3] for cord blood and dividing it by an uncertainty factor of ten to account for variability in elimination half-life and pharmacodynamics variability[4]. It does not take into account bioaccumulation of mercury across the placenta (see section 4 below). Recent studies, however, suggest that measurable neurobehavourial effects may be present at cord blood concentrations near the US EPA reference dose.[5,6,7]

It is noteworthy that the birth cohort studies of mother-child pairs in the Seychelles[8] Islands continue to show little or no effects of mercury exposure despite concentrations similar and even higher than those which have demonstrated mercury-related effects on performance on neuropsychological tests and on electrophysiological and imaging. However, the authors of the Seychelles' studies note that the benchmark dose estimates that serve as the basis for regulatory decision-making have been largely comparable across the Seychelles, Faroese and New Zealand studies. Several hypotheses have been proposed to explain the differences between this fish-eating population and others, such as nutrients in the ocean fish in this area and possible genetic heritage factors. Indeed, in longitudinal analysis of young children's development, positive effects of omega-3 fatty acids were observed as well as small negative effects of prenatal mercury[9] and a study of school achievement showed a slight negative

[1] EFSA (2012)
[2] Rice (2004)
[3] The Benchmark Dose Level is the lower 95th percentile of the dose that corresponds to a specific change in an adverse response.

[9] Stokes-Riner et al. (2011)

association with postnatal mercury in boys[1].

4. Mercury is bio-concentrated across the placenta.

Throughout pregnancy, the placenta concentrates methylmercury and blood mercury concentration in the umbilical cord, which nourishes the foetus, is higher than in the mother's blood. A recent meta-analysis of cord to maternal blood ratios for methylmercury from 10 studies, using different modeling techniques, showed a mean cord to maternal blood ratio of 1.89 with the uppermost 95th percentile of 3.63.[2]. Thus, at birth, the average cord mercury blood concentration will be almost double that of the mother, while for one in twenty that concentration can be over three and a half times more.

Because methyl mercury is concentrated across the placenta, biomarkers of maternal methyl mercury decrease throughout pregnancy as the methyl mercury is taken up by the placenta. Figure 2 shows the decline in hair mercury concentrations during pregnancy for women with different frequencies of fish consumption[3].

For biomonitoring purposes, blood mercury concentrations are measured in women of child-bearing age and not in cord blood. In the study illustrated in the figure below mean maternal blood methyl mercury in the first trimester was 0.48 µg/L and at birth 0.26 µg/L. Mean cord blood concentrations (0.45 µg/L) were similar to mothers' blood methyl mercury concentrations in early pregnancy.

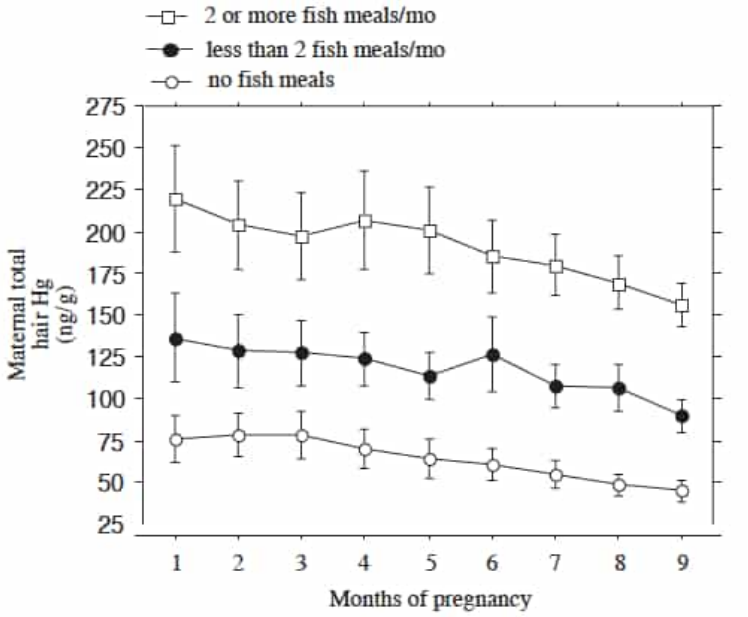
Figure 2. Decline in Hair Mercury Concentrations During Pregnancy for Women with Different Frequencies of Fish Consumption



from Morrissette et al. (2004)

5. Population level impacts can be found at much lower levels of exposure than clear individual impacts (eg. lower IQ). These can have major impacts at a community level.

The threshold concentrations of all of the above-mentioned agencies were based on neurobehavioral outcomes and not on illnesses. These statistically significant but individually subtle effects can greatly impact a community.

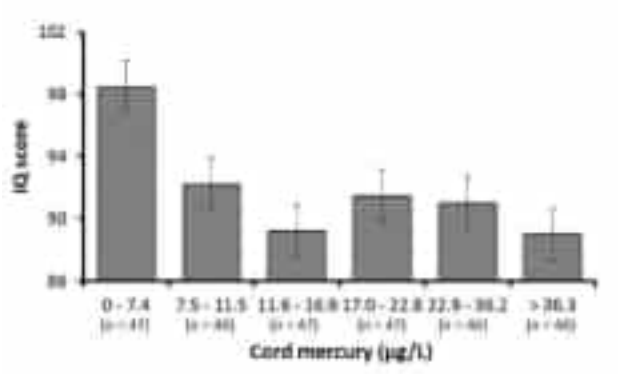
A recent video made by Dr. Bruce Lanphear of Simon Fraser University entitled 'Little Things Matter' (https://www.youtube.com/watch?v=E6KoMAbz1Bw) well describes the impact of very small quantities of toxic substances on children's neurodevelopment. Even **a small decrease in the learning capacity of children in a community has striking repercussions for the community**[1]. For example, an average decrease of 5 IQ points, among exposed children means that, in this community, twice as many children have severe learning difficulties and half as many children are gifted. The effects are amplified if the children have other problems, including poor nutrition, low intellectual stimulation or other toxicant exposures.

In a study of school-age Inuit children from 14 villages in Artic Quebec, children with **cord blood mercury equal to or greater than ≥ 7.5 µg/L were four times as likely to have an IQ score**

[1] Lanphear B. (2015)

below 80, the clinical cut-off for borderline intellectual disability[1], compared to those with lower cord mercury. It is noteworthy that since some of the IQ sub-tests are culturally sensitive, for this study, these tests were modified and validated for this population. The scores ranged from 61 – 125.

Figure 3. Test scores with respect to cord blood mercury in Inuit children 8-14 years old



from Jacobson et al, 2015

6. Developmental impacts of mercury have life-long impacts.

There is increasing evidence that prenatal exposure to mercury has lifelong effects. Subsequent to the Minamata disaster, many children born to asymptomatic mothers with high concentrations of methyl mercury during pregnancy, appeared normal at birth but developed a progressive neurological disorder called Minamata fetal disease[2]. At lower levels, prenatal exposure to methyl mercury is associated with a decrease in children's later cognitive functions, affecting their learning capacity and success in school and in later life.
Recent studies which have examined **long term effect of low-level prenatal exposure on brain activity,** using electrophysiological or neuro-imaging techniques, have confirmed altered brain activity in children with prenatal exposure to mercury[3,4,5,6]

In the United States, researchers have calculated that neurodevelopmental effects of methyl mercury in that country accounts for a loss of $8.7 billion dollars annually in earning capacity[1].

[1] Jacobson et al. (2015)
[2] Grandjean et al. (2010)
[3] White et al. (2011)
[4] Ethier et al. (2012)
[5] Yorifuji et al. (2013)
[6] Boucher et al. (2010)

The authors of the above-mentioned study of prenatal exposure and cognitive effects in Inuit children point out that intellectual disability on school-age IQ is a measure that is predictive of occupational success in adulthood.

In the above-mentioned study of Inuit children, the adjusted[1] mean IQ of the **lowest exposure group was 4.8 points (5%) higher than the others**. However comparing the percentage below 80, the clinical cut-off for borderline intellectual disability: **only 4.3% of the lowest exposure group** were in this category compared to **17.2% for the more exposed.**

In addition, some studies suggest that there may be associations between attention deficits and/or impulsive or hyperactive behaviour in relation to methyl mercury exposure. **The** birth cohort study of **8 – 14 year old Inuit children** shows that **problems of attention and teacher reported symptoms of attention deficits/hyperactive disorders (ADHD) were associated with higher prenatal mercury concentrations, but not current exposures**[2]. In a study in the United States of 8 year old children living near a contaminated site (superfund site), increased risk for inattention impulsive/hyperactive behaviour for boys, but not for girls, was associated with maternal hair mercury, measured close to child's birth, equal to or above 1µg/g.

Several authors have raised the issue of the combined effects of toxic exposures on children's development in communities with other risk factors, such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle. Weiss and Bellinger[3] refer to the 'social ecology of children's vulnerability to environmental pollutants'. The impact of toxic exposures on children who are vulnerable because of other risk factors is greater on the community.

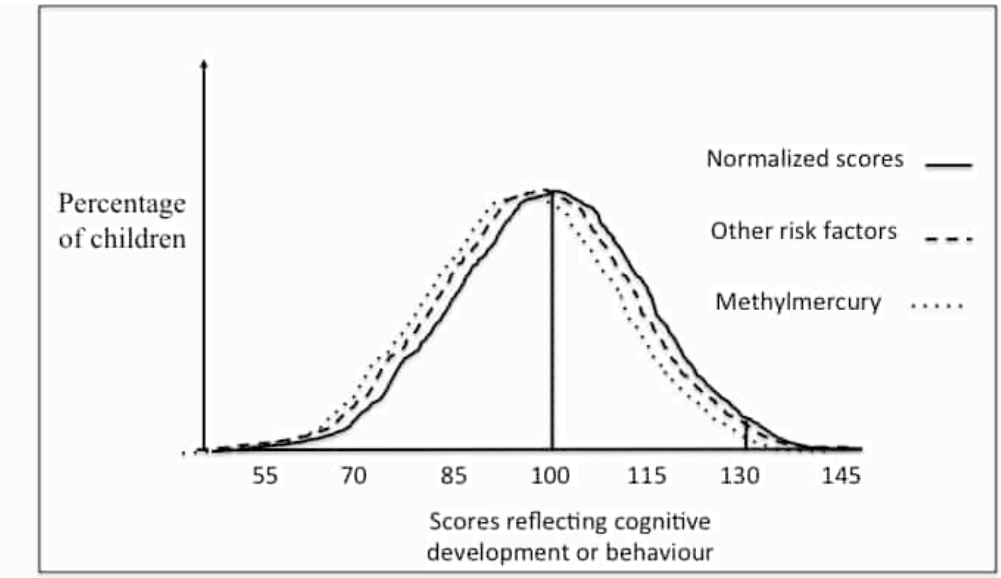
Figure 4 below shows how methyl mercury compounds the effects of other risk factors on intellectual capacities. Children's average cognitive capacities or behavior are influenced by factors such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle, pushing the 'normal curve' towards the left, with more children suffering from learning difficulties. Methyl mercury exposure further pushes the curve towards the left.

[1] In this study, to assess the contribution of mercury, IQ scores were adjusted for cord lead, current PCB153, cord DHA, cord selenium, social environment

[2] Boucher et al. (2012)

[3] Weiss and Belanger (2006)

Figure 4 Estimated distribution of intellectual capacities with methyl mercury exposure combined with other factors. The normal curve moves towards the left, towards lower scores.



The impact of exposure may also be passed on from one generation to the next[1], not only through the fetal environment, but also through the care that parents who function less well because of their exposure are able to give to their children. It can become a vicious circle, as shown in Figure 5. The way in which boys and girls experience these effects may differ[2]. Boys and girls who drop out of school may occupy poorer jobs or no jobs and act out their dissatisfaction in different ways. For girls, early pregnancy may be a further consequence. Although associations between early pregnancy and school achievement, living conditions and income have been studied in aboriginal and non-aboriginal communities[3], the possible contribution of exposure to contaminants to these situations has not been examined.

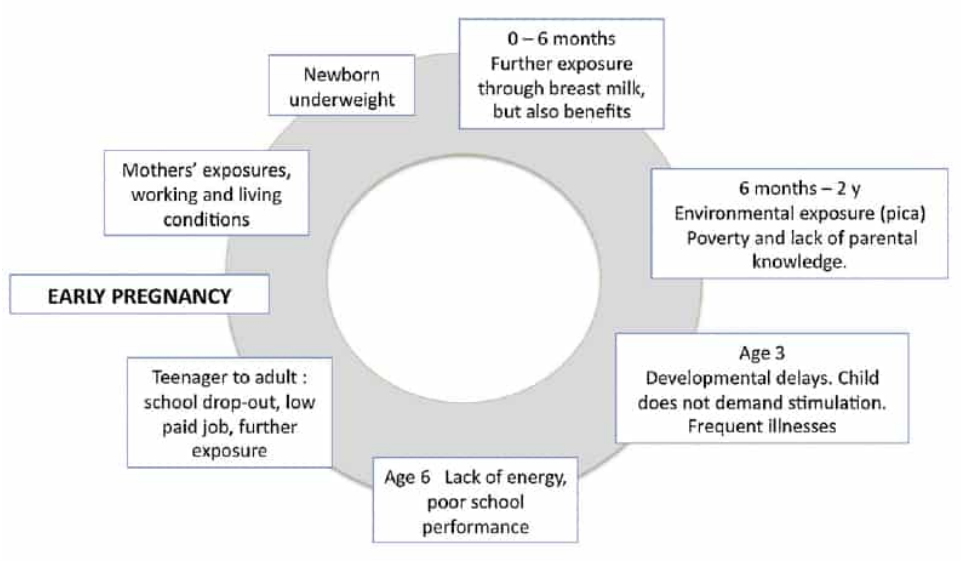
Figure 5 Impact of Environmental Exposure from One Generation to the Next



From Mergler (2012)

7. The health impacts of mercury exposure in adults can take a long time to manifest and can be long lasting and degenerative.

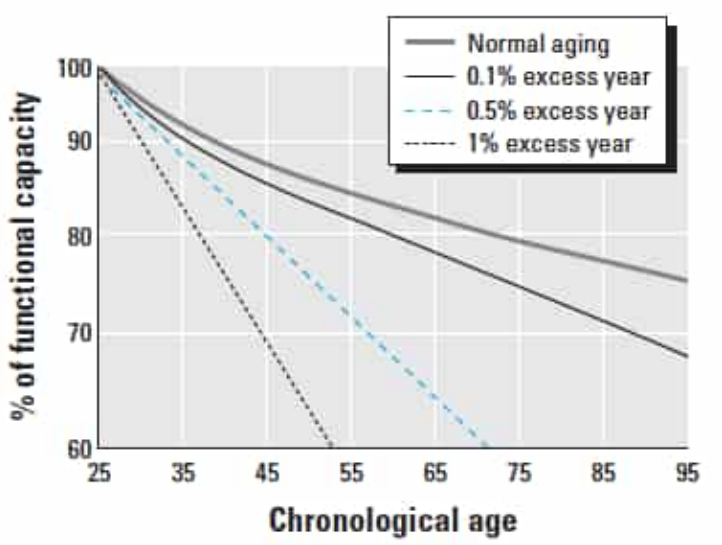
Adverse effects of methyl mercury exposure in adults can result from pre-natal and childhood exposure and/or exposure during adulthood. However, the harm may not be immediately evident. Even with high exposures during adulthood, such as those that occurred in Iraq and in Minamata, there was often a delay between exposure and mild to severe neurological effects exposure, varying from weeks to years[1]. A study in Japan[2] compared the subjective complaints and activities of daily living (ADL score) of a randomly chosen sample of 750 persons, classified into three groups with respect to estimated previous exposure to methyl mercury; all had lived in their current residence for over 40 years. While no difference was observed between exposure categories for the 40-49 year olds, as they got older there was a strong dose-effect relation, with those in the higher group showing the worst scores. Further data from Minamata and the surrounding areas suggest that, in later life, exposed persons display a higher prevalence of psychiatric problems[3], hypertension[4], lower urinary tract disorders[5].

[1] Weiss et al. (2002)
[2] Ushijima et al. (2012)
[3] Yorifuji et al. (2011)
[4] Yorifuji et al. (2009)
[5] Hara et al. (2013)

In adult subsistence fish-eaters of the Brazilian Amazon region, hair mercury concentrations have been associated with deficits in visual functions[1] and motor performance[2]. Age-related decrease in near visual acuity and the prevalence of age-related cataracts were higher among those with higher exposures to mercury[3,4] . In a follow-up study of persons in this region, who continued to eat the same amount of fish, but preferentially those with less mercury, the resulting decrease in hair mercury was associated with an improvement in motor functions, but visual functions continued to decrease in relation to their past exposure levels[5].

Studies of non-human primates dosed with methylmercury, the latency period increased as the dose decreased[6]. In Figure 6, taken from Weiss (2002), the impact of slight increases in loss of functional capacity with age is illustrated. Like with small decrements in IQ in children which have a large impact on society, small decrements in functional capacity with age likewise impact the aging process. Again with poor nutrition, living conditions and access to health facilities, the decrease in functional capacities is greater.

Figure 6 Impact of Slight Increases in Loss of Functional Capacity with Age



From Weiss (2002)

[4] Lemire et al. (2010)
[5] Fillion et al. (2011a)
[6] Weiss (2002)

To better understand the mechanisms involved in adult exposure to methyl mercury, researchers have examined the brains of animals chronically exposed to methyl mercury over a period of time. These studies show extensive alterations in the cortical regions of the brain[1,2] Autopsies performed on the brains of children and adults from the Minamata disaster show different patterns of mercury related impairment, more diffuse in children and more concentrated in specific areas in adults[3].

Methyl mercury from fish consumption has also been associated with chronic conditions in adults although the contribution of previous prenatal and/or postnatal exposure vs. current exposure is difficult to determine. In the study cited above of a Taiwanese population living near a deserted chloralkali plant, there was no historical data and the researchers were unable to determine the contribution of past exposures to their neurologic deficits, which were associated with current exposure concentrations. In this same population, the authors found that current mercury blood concentrations were associated with increased risk of insulin resistance[4].

8. Fish is the most important source of mercury in humans. Other sources of mercury in humans include fish eating wildlife (ducks, otters, etc.), dental fillings, etc. Estimates of mercury impacts based on MeHg or fish alone may underestimate the total impact.

Humans are exposed to both inorganic mercury and organic mercury (usually in the form of methyl mercury). Exposure to inorganic mercury is usually through mercury vapours from occupational and industrial sources; mercury amalgams in dental fillings can also be a source of exposure to inorganic mercury. When inhaled or swallowed, this form of mercury passes passively into the blood and is excreted through the urine. Contrary to methyl mercury, it is not actively taken up by tissues, such as the brain or the placenta and the concentration in mother's blood is similar to that in cord blood[5].

Methyl mercury has been used in industrial processes; the methyl mercury poisoning disaster in Iraq in the early seventies was due to the methyl mercury containing fungicide that was consumed by humans[6]. However, outside of accidental exposures, human exposure to methyl mercury is very largely through fish consumption and to a lesser extent through consumption of fish-eating birds and mammals.

To estimate the total intake of methyl mercury, one needs to consider the entire diet, including

[1] Dasari et al. (2010)
[2] Kong et al. (2012)

[4] Chang et al . (2011)
[5] Morisette et al. (2004)
[6] Grandjean et al. (2010)

fish-eating birds and mammals. The Environment Canada website on mercury in the food chain, updated in 2013 well describes how mercury accumulates through the food chain (https://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=D721AC1F-1).

Some salient points are made in this document :

- *Because mercury is a persistent substance, it can build up, or bioaccumulate, in living organisms, inflicting increasing levels of harm on higher order species such as predatory fish and fish eating birds and mammals through a process know as "biomagnification".*
- *In the environment, particularly lakes, waterways and wetlands, mercury can be converted to a highly toxic, organic compound called methylmercury through biogeochemical interactions.*
- *The most important pathway for mercury bioaccumulation is through the food chain. In the water, plants and small organisms like plankton take up mercury through passive surface absorption or through food intake. … Methyl mercury biomagnifies through the food chain as predators eat other organisms and absorb the contaminants that their food sources contained.*
- *Over time, an individual who consumes plants or prey contaminated with methyl mercury will acquire levels greater than in either its habitat or its food. As a result, top predators acquire greater body burdens of mercury than the fish they consume.*
- *In some cases, methylmercury levels in carnivorous fish, such as freshwater bass, walleye and pike … bioaccumulate up to a million times greater than in the surrounding water.*
- *Piscivorous (fish eating) predators such as loons, merganser ducks, osprey, eagles, herons, and kingfishers, generally have very high concentrations of mercury.*
- *In addition, mercury has been found in predatory mammals such as otters from south central Ontario.*

9. In 1979 the Health and Welfare Canada recommended a limit of 0.2 ppm in fish as a fish consumption limit for Grassy Narrows and White Dog. The limit for possession of fish for sale is 0.5 ppm wet weight.

In 1973, a Task Force on Organic Mercury in the Environment was established by the Minister of National Health and Welfare (currently Health Canada) "in order to respond to the problem of high and unusual mercury levels in relation to the health and well-being of residents of Grassy Narrows and Whitedog, Ontario"[1]. A biomonitoring program was initiated. In 1979, The Health and Welfare Canada recommended a limit of 0.2 ppm in fish for consumption in Grassy Narrows and Whitedog.

[1] cited in Legrand et al. (2010)

The Canadian limit of fish for commercial purposes of 0.5 ppm wet weight is based on the fact that in the general population, fish consumption is not very high. Data from the 2007-2009 Canadian Health Measures Survey (CHMS), which does not include people living on reserves or in remote regions, show that most Canadians eat (82.6%) eat less than three meals of fish and/or shellfish per week. Overall blood mercury levels are low, with median values at 0.81µg/L and the 95th percentile 4.70 µg/L. Blood mercury levels increase with fish consumption. Among pregnant women, 98% are below the Health Canada guideline for blood mercury (8µg/L).

In contrast, a study of diet among 7 Istchee (Cree) communities in the James Bay area showed that blood mercury concentrations 3 – 20 times higher than those reported in the CHMS; blood mercury increased with inland traditional food intake[1]. Another study of persons from the Wapekeka and Kasabonika communities[2] showed hair mercury concentrations 1.5 times higher in persons who ate more than 1 meal of wildlife/week (age adjusted hair mercury concentration (2.96 ± 0.3 µg/g)

10. The Canadian reference dose for preventing fetal neurotoxicity and developmental impacts is double that recommended by US EPA.

In section 2, the different guidelines for mercury exposures are presented. The guidelines were developed to recommend **tolerable daily intake (TDI) or weekly intake (TWI)** of mercury. The Canadian provisional tolerable daily intake for pregnant women, women of reproductive age and infants of 0.2µg/kg body weight/day is twice the US EPA of 0.1µg/kg body weight/day and slightly higher than the proposed revision of the FAO/WHO reference dose (0.19µg/kg body weight/day) (see section 2). The US EPA reference dose is based on **cord blood concentrations**, while the JECFA and Canadian recommendations are based on **hair concentrations**. The Canadian recommendation used a 5-fold uncertainty factor to account for inter-individual variability[3]. The studies that support this recommendation used maternal hair mercury concentrations at birth which are lower than those at the beginning of pregnancy due to placental accumulation (see figure 2 in section 4). All of these reference doses are high for Grassy Narrow since the population has already been exposed to levels that are higher, and in many cases, considerably higher than these.

11. Eating fish has a number of important health benefits. Serious efforts should be made to avoid practices which lead to bio-accumulation of mercury in fish so that the health benefits of fish can be enjoyed while minimizing health impacts from mercury.

Fish is a highly nutritious food, providing a wide variety of nutrients, including omega-3 fatty

[1] Johnson-Down et al. (2015)
[2] Seabert et al. (2014)
[3] Legrand et al. (2010)

acids. In a review of the cardio vascular benefits of omega-3 fatty acids, Mori[1] writes: "Many clinical and epidemiological studies have shown that the polyunsaturated n-3 fatty acids EPA and DHA from fish and fish oils, provide cardiovascular protection, particularly in the setting of secondary prevention. Omega-3 fatty acids beneficially influence a number of cardiometabolic risk factors including blood pressure, cardiac function, vascular reactivity and lipids, as well as having anti-platelet, anti-inflammatory and anti-oxidative actions". Omega-3 fatty acids are likewise positively associated with neuropsychological and neurophysiological outcomes throughout the lifespan.[2,3] Indeed, **today, most studies of mercury toxicity from consumption of fish and fish-eating animals take into account the positive effects of omega-3 fatty acids.**

An article describing a study of myocardial infarction in a Swedish and Finnish cohort well illustrates the benefits associated with omega-3 fatty acids and risks associated with methylmercury from fish consumption[4]. Their model of risk, presented in Figure 7, shows that at lower concentrations of methyl mercury, even a small increase in omega-3 fatty acids can have an important impact in reducing the risk of myocardial infarction, but at higher concentrations of methylmercury, the beneficial effects are counteracted.

[1] Mori (2014)
[2] Bernard et al (2013)
[3] Virtanen et al. (2013)
[4] Wennberg et al (2012)

Figure 7. Risk for Myocardial Infarction with respect to hair mercury concentrations and the percentage of omega -3 fatty acids (s-PUFA) in blood

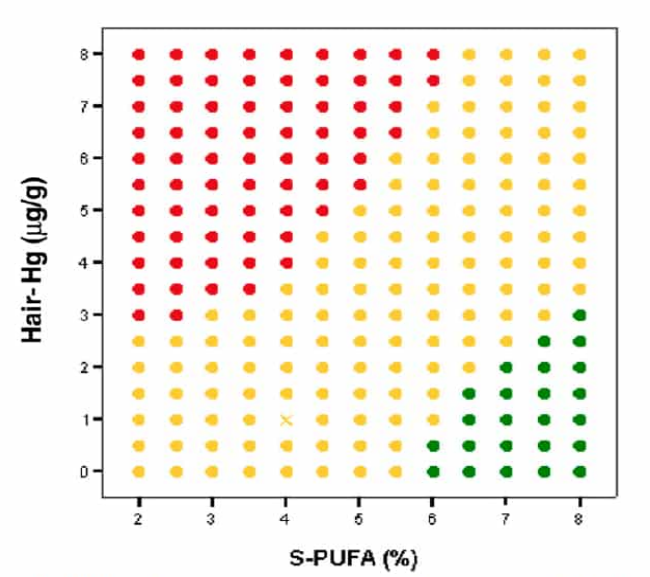

FIGURE 3. Associations of concentrations of long-chain n−3 S-PUFA and Hair-Hg with risk reduction (green circles; upper 95% CI limit for model-based RR <1.0) or increased risk of myocardial infarction (red circles; lower 95% CI limit RR >1.0), with the reference point (RR = 1.0; yellow X) set to S-PUFA = 4.0% and Hair-Hg = 1.0 µg/g; yellow circles denote no statistical evidence of an effect. Hair-Hg, amount of mercury in hair; S-PUFA, PUFAs in serum.

From Wennberg et al. (2012)

Like in many other birth cohort studies, the studies of Inuit children described above, which showed negative effects of prenatal mercury exposure on school-aged children's performance on neurobehavioural tests[1,2], likewise show positive effects of **cord blood DHA**; the benefits and risks are likewise reflected in electrophysiological measurements[3.]

In adult freshwater fish eaters from the Brazilian Amazon, although omega-3 fatty acid concentrations are low compared to consumers of marine fish and mammals, positive effects of omega-3 fatty acids have been observed with better visual functions[4]

The serum omega-3 fatty acids in First Nation inland communities increases with proportion of

[2] Jacobson et al. (2015)
[3] Boucher et al (2011)
[4] Fillion et al, (2011)(2013)

traditional diet meals[1,2]

12. The Ontario Guide for Sport Fish Eaters is not appropriate for Indigenous communities who eat fish as part of their cultural practice. It assumes that fish are eaten relatively infrequently.

The Ontario Guide for Sport Fisher Eaters (2013-2014) indicates that "The advice in this guide is designed for anglers (and their families) who consume moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch. This maximum recommended consumption frequency was based on the results of surveys indicating that most anglers do not consume sport fish more frequently than 8 meals per month. However, many of these fish can be safely consumed more frequently. Anyone who consumes sport fish more frequently than 8 meals per month is advised to contact the Sport Fish Contaminant Monitoring Program (416-327-6816 or 1-800-820-2716, sportfish.moe@ontario.ca." [3]

The US-EPA developed a guide for subsistence fishing with the collaboration of representatives from Native American tribes. It indicates : "EPA recognizes, however, that Native American subsistence fishers are a unique subsistence fisher population that needs to be considered separately. For Native American subsistence fishers, eating fish is not simply a dietary choice that can be completely eliminated if chemical contamination reaches unacceptable levels; rather eating fish is an integral part of their lifestyle and culture. This traditional lifestyle is a living religion that includes values about environmental responsibility and community health as taught by elders and tribal religious leaders. Therefore, methods for balancing benefits and risks from eating contaminated fish must be evaluated differently than for the general fisher population"[4].

13. People who have already experienced elevated mercury exposure, or are showing symptoms of mercury poisoning, may be more sensitive to further exposure than the general population.

Both animal and human studies have shown long latency effects of methyl mercury exposure.[5] Adding further toxic exposure can add further harm to systems that have already been affected. A large number of human and animal studies have shown neuronal and metabolic changes in the absence of manifest signs and symptoms. Persons whose systems have already been altered by previous exposures are more sensitive than the general population.

14. CONCLUSIONS WITH RESPECT TO GRASSY NARROWS

This updated analysis of the scientific literature provides substantial further support and confirm the Chan and Mergler conclusions in the report to the Mercury Disability Board (MDB) in 2009[1] **:**

14a There is no doubt that at the levels of exposure experienced in Grassy Narrows, many people have suffered and are suffering from mercury poisoning.

- Further scientific knowledge of the past 6 years inform us that damage occurs at concentrations much lower than those previously considered harmless, with important impacts not only for individuals but also on the entire community.
- A growing number of birth cohort studies show that the foetus is particularly sensitive to methyl mercury neurotoxicity and even very low concentrations of exposure can affect future cognitive capacity and behavior.
- In 1996, the Research and Development, Environmental Contaminants, Medical Services Branch of Health Canada presented a report on the mercury and child development research project for the Grassy Narrows Band Council[2]. Although the report has numerous methodological problems as regards data analyses[3] and data presentation is confusing, there is information on children's exposure :
    - For the 139 children included in the study, the authors report that between 1978 and 1990 average cord blood concentrations was 8.67 µg/L, with a maximum value of 78.5 and 10% above 20 µg/L.
    - One child born in 1979, who was not included in the study, had a cord blood mercury concentration above 120 µg/g, while another born in 1978 had over 80 µg/g.
    - Overall, there was an important decrease in cord blood mercury concentrations between 1978 and 1991, however, in 1992, there appears to be an increase .
    - The mean hair mercury concentration of the participants at the time of the study was 3.90 g/g with the maximum at 26 µg/g.
    - Figure 8, taken from this report, shows the cord mercury concentrations measured in Grassy Narrows over time.

---

[1] Chan and Mergler (2009)

[2] Research and Development, Environmental Contaminants, Medical Services Branch of Health Canada (1996)

[3] The analyses that were carried out were insufficient to arrive at any conclusions and particularly the conclusion that there were no effects.

- **At these cord blood concentrations, there is consensus from the current scientific literature that there would be effects on children's neurodevelopment.**

Figure 8 Umbilical cord blood levels/year measured in Grassy Narrows

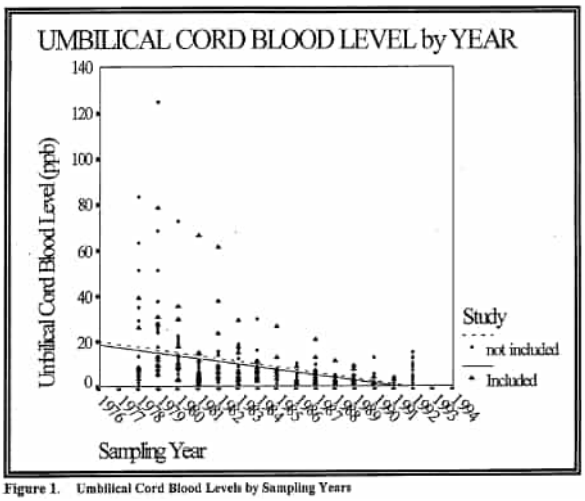

Figure 1. Umbilical Cord Blood Levels by Sampling Years

From the Mercury and Child Development Research Project, Grassy Narrows, Research and Development, Environment Contaminants, Medical Services Branch, Health Canada (1996)

- In a history of Minamata Disease published in 1995[1], Harada describes the diagnosis of the initial cases in 1956. He recounts that by 1960, "while the number of grave cases with acute Minamata Disease in the initial stage was decreasing, the numbers of chronic Minamata patients who manifested symptoms gradually over an extended period of time was on the increase."
- Recent studies from MInamata, supported by findings from animal research, show that methyl mercury accelerates the aging process.
- A large number of animal studies and several human electrophysiological and imaging studies are elucidating the mechanistic basis for mercury neurotoxicity.
- While the nervous system is the primary target organ for methyl mercury, studies indicate that the cardiovascular system and metabolic pathways may also be affected by methyl mercury.

[1] Harada (1995)

14 b. The scientific literature continues to support Dr. Masazumi Harada and colleagues' clinical findings, reviewed by Chan and Mergler for the MDB[1] on the similarities between the neurologic signs and symptoms of persons from Grassy Narrows and White Dog and Minimata Disease in Japan.

- In their early reports[2,3], Harada and colleagues had examined 89 persons from Grassy Narrows and Whitedog and indicated that no one presented all of the classical signs and symptoms of Minamata Disease, although many persons presented one or more classical signs of the disease. Although they did not carry out statistical analyses, they provide evidence of dose-effect relations.

- In 2002[4], the same neurologists examined 57 persons of whom 9 had been examined in 1975. The authors classified 11 of the 57 persons with Minimata Disease, 12 with Minamata Disease and other complications and 22 with "light Minamata Disease".

- None of the persons Harada found with levels over 50 in 1975 survived to be re-tested in 2002. Of the 9 who were re-examined none fell into the Minamata Disease category, but for 7 of the 9, symptoms and signs had worsened.

- In 2004, this team examined 187 persons, among whom they identified 60 of Minamata Disease and 54 cases of the disease with complications. Twenty seven had participated as well in 1975. In their review of Dr. Harada's follow-up studies (1975 - 2004)[5], the Chan and Mergler report point outs that **the most valuable information of this report was the evolution of neurologic signs and symptoms consistent with mercury poisoning in those that were tested in the two periods.**

- In 2011, Harada and his co-workers[6] wrote a review of the work that they had carried out in Grassy Narrows and White Dog since 1975, including a further study carried out in 2010. In 2010, they performed neurologic assessments of 73 persons from Grassy Narrows and 87 from White Dog over 20 years old. The report indicated that under the diagnostic criteria used in Minamata City, 33.7% of the group that they examined were diagnosed as Minamata Disease patients; and 25.0% as suspected Minamata Disease cases (see more details in answer to question 1.1 c) .

---

[1] Chan and Mergler (2010)
[2] Harada et al. (1976)
[3] Harada et al. (1977)
[4] Harada et al. (2005)
[5] Harada et al. (unpublished report)
[6] Harada et al. (2011)

- Using the findings from the 2010 examinations, Takoaka and coworkers[1] compared the neurologic signs and symptoms of 80 volunteers aged 16 to 76 from Grassy Narrows and Japanese exposed and control groups. From the observed similarities, particularly between the Grassy Narrows older group and the Japanese exposed group, the authors conclude that "clinical signs and symptoms of the residents of Grassy Narrows are almost the same as those recorded for Minamata disease in Japan." (see more details in answer to question 1.1 d)
- It should be noted that Dr. Harada and his team sought to determine whether persons exposed to mercury in Grassy Narrows and White Dog presented a neurological clinical profile similar to Minamata Disease. While they identified cases and possible cases using the Minamata Disease criteria, they did not examine the possible contribution of mercury into other disorders or the impact of more subtle changes of nervous system functions, particularly during foetal exposure and childhood, which occur at lower concentrations of exposure. .
- Both Harada et al (2011) and Takaoka et al (2014) mention that the participants in their studies presented a high prevalence of several health disorders, including hypertension and diabetes among the participants, **but the possible contribution of mercury to these conditions has not been examined.**

14 c. Because of mercury contamination in the region, the people of Grassy Narrows were obliged to reduce their consumption of local fish and wildlife and were thus deprived of healthful nutrients, which have been shown to be beneficial for a large number of physiological functions and to be preventive for many and diseases.

- The historically high mercury concentrations in fish forced the community to greatly decrease their fish and wildlife consumption, depriving them of the nutritional and social benefits[2] of a traditional diet.
- In a 2003 study of 87 persons from Grassy Narrows[3], 61% reported that they currently fish in the surrounding area, 31% reported that they used to but no longer had fished in the area, and 8% reported they have never fished in the area. Of these participants, 9% reported eating more traditional food compared to 10 years ago, 55% reported eating about the same, and 36% reported eating less. Reasons provided for a decrease in the consumption of traditional foods included
    - changes in the family structure;
    - decreased hunting and fishing practices;
    - decreased availability;

[1] Takaoka et al. (2014)
[2] Wheatley and Wheatley (2000)
[3] Chan (2005)

  - concerns about the safety/contamination of the food;
  - the convenience of market foods.

- Although there has been marked decrease in mercury in fish in the English-Wabigoon River system,[1] recent concentrations of mercury in fish[2] and fish-eating wildlife[3] oblige the community to limit consumption of fish and wildlife.
- Kinghorn et al[4] analyzed fish mercury concentrations in 4 fish species from seven lakes in the Grassy Narrows territory and describe the relation between fish length with respect to mercury concentration. They note that the fish harvested from Grassy Narrows lakes show stronger associations between fish length and mercury compared to those from the Wabaseemong territory. The authors indicated that this may be because "these lakes are closest to the Dryden spill site. Higher levels of mercury in the sediment of these lakes may affect the rate of uptake of mercury in the fish that live predominantly within them."
- For a report in 2005, Chan calculated mercury intake and hair concentrations for 87 persons from Grassy Narrows and 55 from Wabaseemoong measured in 2003. In Grassy Narrows, the average yearly local fish consumption in Grassy Narrows was 20g/day, but in older men (+61 years of age) it averaged 60g/day. When all of the hair segments were analyzed, mean hair mercury was 1.3 µg/g with a maximum of 7.1 µg/g. The highest individual hair segment was 15.5 µg/g. Hair mercury increased with mercury intake from fish consumption. In 2004, Harada reported that one persons had a concentration of 25 µg/g and 2003, Chan reported that persons from the White Dog area had hair concentrations of 60µg/g.
- The 2012 report on fish Contaminant Monitoring near Grassy Narrows First Nation by the Environmental Monitoring and Reporting Branch Ontario Ministry of the Environment[5] shows elevated mercury in the 50 km area around Grassy Narrows in walleye and much lower concentrations in Whitefish. For walleye, with the exception of one site where the report indicates that fish can be eaten with restriction, all the other sites indicate DO NOT EAT. Whitefish present much lower concentrations, which may still pose a risk to subsistence eaters.
- The 2012 above-mentioned report presents separate values for sensitive populations, defined as women of child-bearing age and children under 15 years old, and for the general population. Given the recent information on mercury reviewed above, a population that has already suffered effects from mercury contamination and other harmful risk factors for poor health may also be considered 'sensitive'.

Grassy Narrows : a sensitive population

- Prior to the events and poisoning that occurred due to mercury contamination, the Grassy Narrows community had undergone important upheaval that negatively impacted their lives and lifestyle.[1,2,3] The toxic effects of mercury would compound the effects of these stresses on the nervous system and their health status.

- Because of the high prevalence of disease, coupled to mercury intoxication, in the communities of Grassy Narrows and White Dog, in the 2010 MDB report, Chan and Mergler point out " It is paramount that members of the two communities receive the necessary medical care and support. In contrast, residents in Minamata, Japan enjoy superb health care from neurologists and therapists even they had not officially been classified as victims of Minamata Disease".

- It is surprising that although the Japanese neurologists have identified many cases of Minamata Disease in Grassy Narrows and many persons have illness that have been associated with mercury intoxication, there has never been a scientifically sound epidemiologic study of the impact of pre and post natal mercury exposure on the health and well-being of this community.

- There are many sources of mercury contamination. The river and lake systems around Grassy Narrows have been polluted by industrial activities; hydro-electric reservoirs and logging can also contribute to the mercury burden in this ecosystem. Any increase of exposure to this already 'sensitive' community would further compound the harm to the health and well-being of the present and future generations.
